The forty-fifth annual report of the Imperial Cancer Research Fund was presented to the annual meeting held at the Royal College of Surgeons on April 21 with the Earl of Halifax, president of the Fund, in the chair. The Fund continues to be well sustained by the gifts of the public. Last year these amounted to £14,000—an increase of £10,000, due to a single donation of that amount. The public support is the more noteworthy because to the bulk of people these annual reports must be as remote as if they were written in one of the less familiar foreign languages.

Several members of the scientific staff have been engaged since 1939 in the study of Bittner's milk virus of mouse mammary cancer, but it is admitted that it is difficult to feel absolute confidence in the conclusions so far reached. There are some indications that infection of the mouse with the milk virus occurs by way of the lymphatics of the nasopharynx, but those concerned are hesitant to draw this conclusion because of certain experimental difficulties.

An investigation of spontaneous mammary tumours in the mouse is proceeding on the hypothesis that spontaneous mammary cancer is dependent upon the combined action of three factors—an inherited tendency, the action of oestrogen, and the presence of a virus. Experimental animals have been obtained by mating low-cancer-line females with high-cancer-line males, and in certain matings of this kind the hybrids have been found always free from mammary cancer. Experiments reported previously had indicated that adenomas in mouse mammae might be regarded as evidence of the presence of the milk factor of mammary cancer, provided that an amount of oestrogen detectable by vaginal cornification was present in the mice bearing the adenomas. An account is now given of further work in this field, which, however, has not yet reached any decisive conclusions. Quantitative data are urgently called for in the many problems involving the use of the mouse mammary gland.

Some work on the action of thiol compounds in the induction of skin cancer in mice by synthetic carcinogens is almost completed. The anti-carcinogenic property of BAL, the most potent thiol used, has been found to be much lower than its therapeutic properties in arsenical poisoning. All the thiol compounds tested, in particular BAL, are less potent as inhibitors of skin tumour induction than such substances as bromobenzene or maleic anhydride.

One of the members of the scientific staff has been engaged in a critical study of the situation in the field of viruses in relation to cancer, but this work also is not sufficiently advanced to justify a report of the findings. One problem that has arisen may be mentioned. It has been found desirable to preserve active homogenized stocks of transplantable tumours for comparative and quantitative studies. Forty years ago Salvin Moore successfully transplanted mouse carcinomata and sarcomata after exposure to the temperature of liquid air, and other workers have grown sarcomata after freezing them with CO₂ snow. The general conclusion has been that it is possible for a few cells to remain viable though exposed to freezing temperatures, and certain aspects of this problem are now being studied with the immediate objective of further improving this potentially valuable method of preserving certain transplantable tumours.

Another continuing investigation concerns the action of chemical substances on cancer. As yet no compound examined has shown a specific lethal action on cancer cells. The members of the scientific staff at Mill Hill under the Director, Dr. W. E. Gye, number eight, with one visiting research worker.

Sir Harold Gillies, consultant adviser to the Ministry of Health and Scottish Department of Health, left Britain on April 24 for a 3-weeks tour of Yugoslavia under British Council auspices. He gave lectures and demonstrations on plastic surgery at Belgrade and in provincial centres. Sir Harold is already well known in Yugoslavia, for in 1946 he was leader of the Unrra plastic surgery team there.

Preparations and Appliances

A "TRILENE" BY-PASS TAP

Dr. A. H. GALLEY, assistant anaesthetist to King's College Hospital, writes: It is now generally accepted that trichloroethylene ("trilene") must not be used during closed-circuit anaesthesia owing to the possibility of the formation of breakdown products which can produce cranial-nerve palsies. Until Marrett (*Journal*, Feb. 28, p. 403) introduced his apparatus a few weeks ago, however, there was no anaesthetic machine on the market with a safety device to prevent the use of trilene when the absorber circuit was in operation. For some time I have been engaged in designing a simple attachment which

FIG. 1.—The by-pass tap.

could be incorporated into a Boyle apparatus—the most popular anaesthetic machine—to achieve this object. As will be seen from Fig. 1, it consists of a by-pass tap; and Fig. 2 shows how it can be incorporated between the ether and trilene bottles (the rubber tube cut short in Fig. 2 would normally be connected to the CO₂-absorber circuit). When the tap is turned to the left ("absorber" position) the

gases from the flowmeters and ether bottle are short-circuited to the CO₂ absorber by a permanently attached rubber tube (cut short in the photograph), thus by-passing the trilene bottle and preventing the possibility of this anaesthetic from gaining access to the closed circuit even if the trilene tap is inadvertently left "on." When the by-pass tap is turned to the right ("open" position) the machine can be used in the usual manner with the Magill semi-open rebreathing-bag assembly.

FIG. 2.—The by-pass tap incorporated into the Boyle apparatus.

It will be noted that the trilene bottle has to be the one furthest from the flowmeters in order for this device to work; some machines have the trilene (or chloroform) bottle nearest to the flowmeters, but the change-over can be effected quite simply by unscrewing and interchanging the glass containers for ether and trilene. Fortunately, Boyle's apparatus is usually built on the unit system—i.e., flowmeter unit, ether-bottle unit, etc.—and the by-pass tap has been designed as a small unit which readily fits into place (Fig. 2). The tap illustrated has been made for me by Medical and Industrial Equipment Ltd., of 12, New Cavendish Street, London, W.1, to fit their own machine, but they are able to supply a similar tap to fit any Boyle's apparatus designed on the unit system.

Reports of Societies

HYPOTHALAMUS AND WATER METABOLISM

In the Section of Endocrinology of the Royal Society of Medicine on April 28, with Mr. L. R. BROSTER in the chair, the subject under discussion was the hypothalamus and water metabolism.

Dr. G. W. HARRIS said that it was possible for the hypothalamus to influence water metabolism through the sweating mechanism, through vasomotor control, and through the pituitary gland. He confined his remarks to the effect exerted by the pituitary. Both the posterior and anterior pituitary affected water metabolism. It had been shown many years ago that the intravenous injection of posterior pituitary extract decreased the urinary flow. He described experiments with rabbits to ascertain the effects on the diuretic process of stimulating the pituitary stalk: there was an abrupt diminution in the urinary output and this antidiuretic effect was maintained for a long period. The extent of this inhibition varied according to the position of the stimulating electrode in relation to the hypothyseal tract and the intensity of the stimulation. As the urinary output fell the relative chloride output increased. As urinary output recovered, the chloride secretion fell. Most of the endocrine glands seemed to be under nervous control. The position would be clearer if it were possible to demonstrate how the nervous system affected the secretion of the anterior pituitary.

Dr. W. J. O'CONNOR described some recent work carried out by Prof. Verney on dogs, the results of which showed the effect on diuresis of changes in the osmotic pressure of the blood in the carotid arteries.

Clinical Significance.

Dr. RAYMOND GREENE drew attention to the clinical significance of these experiments. Before he knew anything about the early work of Prof. Verney and his collaborators he was impressed by the fact that extreme and prolonged anxiety in human beings did not, as was often asserted, give rise invariably to loss of weight. He had collected a series of cases in which anxiety had apparently produced a sudden and rapid increase of weight, which was in his view due rather to water retention than to true obesity. He outlined the case of a woman who was married in 1939, when her weight was 56 kg. Her husband went abroad and was missing at Singapore. As soon as the news of the tragedy reached her she began to put on weight. She was treated by a low carbohydrate diet without avail, and then with a diuretic in addition. Her weight fell slightly but did not return to its normal level. She was taken into hospital, where her weight again fell, but as soon as she went back to her job it rose again. After about a year she formed a new attachment and forgot about dieting. Her mental health improved, and her weight in a very short time went down to normal. He thought that this was an example in clinical medicine of what might be called Verney's syndrome. In response to anxiety there was an increase in the output of antidiuretic substance from the posterior pituitary and an increase in weight, which was usually taken to be obesity, but was in fact an accumulation of fluid in the body.

In the course of the discussion which followed one member asked how nervous polyuria fitted into this picture, and another whether the posterior pituitary had any effect on salivary flow. Another question was, Could this work be applied to nocturnal enuresis in children, who had water retention during the day and at night an uncontrolled polyuria. Dr. Raymond Greene said that he felt sure that the suggestion concerning enuresis was correct. He had asked mothers who brought such children to him about the colour of the urine passed during the night, and in a fair proportion of cases, though not in all, the mothers had been struck by the fact that, whereas the child passed a deeply coloured concentrated urine during the day, the urine

passed at night was so free from colouring matter that the sheets were not stained.

Dr. O'Connor said that in the experiment he had described all the dogs had been subjected to what was in effect a sympathectomy. The operation was designed to prevent nervous influences acting on the kidney. If an emotional stress was produced in a normal dog an increase in the production of antidiuretic substance was the exception rather than the rule, whereas in the partially sympathectomized dog there would be an increase. That might be of interest in connexion with nervous polyuria in that nervous excitement was not necessarily associated with increased output. He knew of no convincing evidence that the amounts of antidiuretic substance had any effect on salivary flow.

LEMPERT FENESTRATION OPERATION

RESULTS IN OTOSCLEROSIS

Dr JULIUS LEMPert, of New York, addressed an unusually crowded meeting of the Section of Otology of the Royal Society of Medicine on May 7 on his fenestration operation for the restoration of hearing in clinical otosclerosis. He showed a colour film, which ran for nearly an hour, illustrating every detail of the operation. His remarks were based upon a continuous study and analysis during the past ten years of the results of 3,700 fenestration operations, of observations made in the performance of 450 revisions, and of the histological findings in animal experiments.

Pre-operative and Operative Factors

Dr. Lempert said that, while it was important to have pure tone audiometer tests both by air and bone conduction, these must be supplemented by the tuning-fork (512, 1024, and 2048 d.v.) and voice tests. No otologist should ever perform a fenestration operation without first personally testing the patient to determine the chances of restoration of practical hearing. He should never work on the findings of another otologist. Only the development of simple uncomplicated tests would be acceptable in the long run. If following a well-performed fenestration operation an impressive improvement in hearing could not be demonstrated audiometrically, it might be assumed that the cochlear functional reservoir was incorrectly evaluated pre-operatively.

The creation of a new vestibular fenestra to replace the functionally impeded oval window resulted in improved mobilization of endolymph by air-borne sound, which in turn could result in restoration of practical hearing, if the existing cochlear nerve function was adequate. A tympanic air space hermetically sealed by the tympanic membrane was essential following fenestration so that the endolymph could be mobilized by air-borne sound out of phase. The newly created vestibular fenestra must be sealed by a viable tympano-meatal flap to protect the membranous labyrinth from degeneration, which would lead to a total loss of hearing.

Post-operative Factors

The danger of post-operative infection had been largely overcome by the use of systemic penicillin. As a result of experience gained with revisions and animal research it had been found that osteogenetic closure of the fenestra was mainly influenced by (1) the site chosen for the creation of the fenestra, (2) the inherent natural tendency for osteogenetic repair to take place in the freshly injured histological bony layer of the fenestra rim, and (3) bone dust and bone splinters left behind in the region of the fenestra gap and within the perilymphatic space.

He spoke in particular of these bone particles, which, if they were not meticulously removed, would endanger the result of the operation. Every careful otologist practising fenestral surgery must have observed that in fracturing and

pulverizing this region bone dust and splinters unavoidably fell into the perilymphatic space and were irretrievable. He was convinced that they were a much more serious threat to the maintenance of practicable serviceable hearing as a result of fenestral surgery than bone dust and splinters resting in the region of the fenestral rim. His new technique had been developed with a view to preventing the creation of bone splinters and bone dust, and he illustrated pictorially how by working with a burr the bony capsule was slowly and gradually worn down and bone dust prevented from falling within the space.

Assessment of Results

Careful post-operative testing by pure tone audiometry and its comparison with pre-operative audiometric readings was the most scientific method of evaluating the results obtained. A patient's statement that his hearing was improved following operation was acceptable only when it could be audiometrically substantiated. There was no clinical evidence of secondary cochlear nerve changes in these cases, but as such changes had only rarely been observed in the non-operated ear of the patient the conclusion that the operation prevented such changes could not as yet be drawn. Following the successful performance of the fenestral operation in one ear an improvement of hearing in the non-operated ear had never been observed.

Finally Dr. Lempert said that the balanced technique whereby the fenestra was created in the dome of the vestibule when carefully performed could result in the restoration of permanent, serviceable, unaided hearing, acceptable both to the otologist and to his patient, and there was evidence that the "bone-dust-free nov-ovalis" technique would prove to be another successful advance. He then showed by means of his film the entire technique of the operation, from the pre-operative examination of the patient to her return to the consulting-room three weeks after operation for demonstration of what appeared to be a perfect result.

Permanence of Results

No time was left for discussion, but Mr. TERENCE CAWTHORNE, Mr. SIMSON HALL, and the President of the Section, Mr. DONALD WATSON, joined in tributes to the lecturer and raised a few further points, to which Dr. Lempert replied.

Dr. Lempert said that of 100 found suitable for this operation 80 would be found immediately after operation to have had their hearing restored to the practical level for the three speech frequencies, but after two years only 60 of those 80 would be found to have maintained such hearing. In other words, 75% of those who had been successfully operated on showed the permanent result of good unaided hearing. This percentage might be increased when the cases in which bone dust had been avoided came to have their results assessed. It was necessary for the patient to stay in bed for about five days after operation; the patient could leave hospital in ten days, and a week afterwards should be going about his affairs as usual.

To avoid post-operative infection the most satisfactory means was to promote rapid healing. In the ordinary way with prompt skin grafting there should be a dry and completely healed cavity within three weeks. But there were cases which would stay dry for a while and then begin to desquamate. Some mild staphylococcal infection might occur. He had tried many things. Sulphathiazole powder answered in some cases, but not in all, and the same was true of sulphadiazine, gentian violet, and plain boric acid. The worst thing to use was silver nitrate.

In submitting patients to this treatment, Dr. Lempert continued, regard must be paid to the importance to them of unaided hearing. Quite 80% of the deafened people who came to him wore hearing-aids and could hear very well with them, but they wanted operation in order that their infirmity might not be apparent. They did not want to be seen with a "crutch," and therefore they submitted to the fenestration operation. But if they could make their social and economic contacts satisfactorily with a hearing-aid there was no justification for the operation.

SOCIAL MEDICINE

The Section of Epidemiology and State Medicine of the Royal Society of Medicine, with the president, Dr. W. S. C. COPEMAN, visited the Institute of Social Medicine at Oxford on April 23. The director, Prof. J. A. Ryle, welcomed the visitors in an introductory address in which the aims and organization of the Institute were described. The afternoon session was devoted to short communications by members of the scientific staff and to demonstrations of modern mechanical methods for recording and analysing statistical data.

Industrial Accidents

Dr. W. T. RUSSELL dealt with industrial accidents, primarily from the statistical aspect. The importance of well-designed record cards and of co-operation between operatives and supervisors in reporting all accidents, however trivial, was stressed. Before 1921 statistical records were on an industrial rather than an occupational basis, with the result that high-risk operations might be diluted or even masked by being placed in the same category as low-risk operations in the same industry. Although occupational morbidity figures tended to be influenced by selective recruitment on account of aptitude or fitness for particular types of work, they were generally more reliable than mortality rates. The old and the unfit tended to seek lighter work, and only the last occupation was recorded on the death certificate.

Despite recent improvements, due partly to legislation and partly to voluntary effort, industrial hazards remained an important factor in loss of production, with 230,000 recorded accidents and 826 fatalities in England and Wales in 1946. In a recent survey the accident and sickness records were correlated and compared at different age groups. The rates were much higher than the averages at ages under 20 years and continued to decline even after the age of 50.

Details were given of an investigation by Drs. A. M. STEWART and J. P. W. HUGHES into the incidence of tuberculosis in the boot and shoe trade in Leicester and Northampton, which is approximately twice as high as in comparable groups in other industries in these areas. This was known as long ago as 1915, when the first M.R.C. report on the subject was published. With the aid of mass radiography and detailed analyses of the collected data according to age, job, and environment, valuable conclusions emerged. Although there was little evidence to show that leather or other materials were contaminated, the homes and the working conditions in the smaller factories were far from satisfactory.

The effect of excessive fluorine in the water supplies in certain areas on the incidence of dental caries and fluorosis and on the aetiology of juvenile osteochondritis (Scheuermann's disease) was discussed by Drs. F. H. KEMP and D. C. WILSON, who showed specimens and radiographs. An animated discussion followed on the papers and on different aspects, present and projected, of the work of the Institute.

The building up of local health services of a uniformly high standard throughout London should be one of the benefits of the National Health Service, declared Mr. John Edwards, Parliamentary Secretary to the Ministry of Health, when he opened the Caversham Road Day Nursery, St. Paneras, London, recently. In London maternity and child welfare and school health services were at present subject to a patchwork of controlling bodies. The services were interrelated and should be under a common control. That was one of the things which the National Health Service Act brought about. From July 5 the L.C.C. would be responsible for providing all those services. That, besides enabling the highest degree of co-ordination to be obtained, would make possible the building up of local health services of a uniformly high standard throughout the country. Continuity of the health services for children would be secured from infancy onwards, since the County Council was both the local health authority and the local education authority. But the L.C.C. had wisely recognized that it was important that the management of those domestic health services for which they were to be responsible should not become remote and impersonal, and that the metropolitan borough councils should be linked with the work. For these reasons the County Council had decided to entrust the day-to-day management of the services to divisional health committees, of which there would be nine, each covering a portion of the county.

Correspondence

Erythroblastosis and Kernicterus

SIR,—According to the annotation on this subject (May p. 843) based on a paper by Wiener and Brody, icterus gravis due to bivalent antibodies which, though normally too large to pass through the placenta, are "milked" into the foetal circulation by the uterine contractions during labour and produce thrombosis in the foetus causing jaundice, erythroblastosis and kernicterus; whereas univalent antibodies pass into the circulation during pregnancy and produce a progressive anaemia and in severe cases stillbirth or hydrops foetalis, kernicterus not being a common sequel. Moreover, the infant with icterus gravis is normal when born, but develops jaundice and toxæmia shortly afterwards: transfusion is useless, though transfusion with Rh-negative blood of a suitable group is the best treatment for infants showing progressive anaemia and hydrops. The annotation concludes with the words, "These findings are important, and they serve as another example of the need for backing laboratory hypothesis by clinical observations."

We agree with this conclusion and suggest that it should be applied to the statements made by Wiener and Brody, while the writer of the annotation appears to accept. We would therefore ask how the following clinical and pathological observations can be explained on the theory of Wiener and Brody: (1) Icterus gravis cannot be prevented by caesarean section carried out before the commencement of labour. (2) Occasionally an infant with icterus gravis is jaundiced at birth, and the amniotic fluid and vernix caseosa are stained yellow. (3) Erythroblastosis may occur in the normal newborn baby and is frequently found in haemolytic anaemia of the newborn and is present to an intense degree in hydrops foetalis—conditions in which according to Wiener and Brody plugging of the marrow vessels does not occur. (4) Prolonged search has never revealed occlusion of blood vessels by agglutination thrombi in kernicterus. (5) Normal cells are found in close proximity to "ghost" cells in the areas affected by kernicterus. (6) The occurrence of kernicterus in babies in whom iso-immunization has been excluded. (7) Haemolytic anaemia of the newborn is not usually present at birth, but develops on the second and third day of life. (8) Kernicterus has never been found in association with haemolytic anaemia of the newborn. (9) Transfusion with Rh-negative blood has in our experience almost halved the mortality rate of haemolytic disease of the newborn.—We are, etc.,

Poliomyelitis and Lymphocytic Meningitis

SIR,—Dr. J. Egerton Caughey (May 8, p. 903) has drawn attention to apparent discrepancies in two recent papers dealing with acute poliomyelitis for which I was wholly or partly responsible.

1. Regarding the 1941 outbreak of acute poliomyelitis amongst New Zealanders serving in Egypt, I had hoped that my reference to this in a paper read before the Royal Society of Medicine in 1945 might have shown Dr. Caughey that, though I had been unwilling in 1941 to accept his view of this outbreak, further experience of the disease had convinced me that he was right in labelling his cases of lymphocytic meningitis as non-paralytic cases of poliomyelitis.

2. In the second paper he refers to (McAlpine, Kremer, Buxton, and Cowan, *British Medical Journal*, 1947, 2, 1019) reference was made to the incidence of acute benign lymphocytic meningitis in British troops in Egypt. Three reasons for believing that these were not cases of poliomyelitis were: first, that acute poliomyelitis did not occur in epidemic form amongst British troops in Egypt between the years 1941-5; secondly, that the cases of benign lymphocytic meningitis greatly exceeded the sporadic cases of poliomyelitis; thirdly, the degree of pleocytosis in the C.S.F. was greater than in poliomyelitis, counts of over 500 cells being not uncommon.

Therefore, though I feel sure that Dr. Caughey was correct in his interpretation of the 1941 outbreak amongst the New

universal prescription in pregnancy

Common to expectant mothers throughout the world is the tendency towards a deficiency of iron, of calcium and of vitamin D. The foetus makes imperious demands upon maternal reserves of these factors and, when the diet fails to make good these demands, the mother's health must inevitably suffer. Caldeferrum Tablets have the specific purpose of safeguarding maternal health by ensuring a nutritionally sufficient intake of iron, calcium and vitamin D. Four tablets daily supply more than the mother's estimated requirement of iron, calcium up to five-sixths of the estimated need, and ample vitamin D to ensure efficient assimilation of the calcium. Indeed, this simple routine represents a fundamental step towards nutritional 'well-being' in pregnancy and is wisely continued during the lactating period.

CALDEFERRUM

Four tablets provide ferrous iron, 25 mg., calcium 0.5 gm., and D. 2,500 i.u.

GLAXO LABORATORIES LTD., GREENFORD, MIDDLESEX, ENGLAND. Other laboratories are in operation at Elkhart, Indiana; Barnard Castle, Durham, England; and Uxbridge (under construction). In Argentina, Australia, India, Italy and New Zealand. Agents represent every country in the world.

ALBU CID
ORAL TABLETS

For the treatment of urinary tract infections

Sulphacetamide, by virtue of the following properties, is particularly suitable for and effective in the treatment of urinary tract infections.

- ★ Relatively high solubility in the urine.
- ★ Over 70% excreted as ACTIVE sulphonamide.
- ★ Active against the common causative organisms.
- ★ High toxicity threshold.

'ALBUCID' is sulphacetamide of British Schering manufacture

than the architect

In comparison with the population as a whole, the professional classes seem especially prone to Diabetes Mellitus.

In the treatment of Diabetes Mellitus, the use of Insulin is now universal. Insulin-Boots is prepared from pure crystalline Insulin and tested in accordance with the regulations made under the Therapeutic Substances Act, 1925.

Supplied in rubber-capped vials as below:

20 units per c.c. Vials of 5, 10 and 25 c.c.

40 units per c.c. Vials of 5 and 10 c.c.

80 units per c.c. Vials of 5 and 10 c.c.

Zealanders, I believe that another virus was responsible for the majority of the British cases of benign lymphocytic meningitis. As far as we could ascertain at the time this was not the virus of choriomeningitis.

It would be of great interest to us here if Dr. Caughey would give us his impressions of the 1947-8 outbreak of acute poliomyelitis in New Zealand, especially as to the incidence of unusual types of the disease.—I am, etc.,

London, W.1.

DOUGLAS McALPINE.

Juvenile General Paralysis

SIR.—I was very interested in the account of Dr. W. Liddell Milligan's case (May 8, p. 881), but a somewhat similar case which I encountered some years ago leads me to doubt the correctness of his conclusion, namely that a case of juvenile general paralysis had sustained a spontaneous remission.

In 1933 I was consulted by a mother regarding her son, aged 10 years 5 months, who a few months previously had begun to exhibit major epileptic attacks. In childhood, from the age of 1½ to 3½, he had suffered from "convulsions," but had been quite free from fits of any kind until he had reached his eleventh year. The patient was a well-developed, intelligent boy with no stigmata of any kind. Concomitantly with the reappearance of fits he had changed a good deal temperamentally, becoming irritable and difficult, and often refusing to go to school, etc. Purely as a "shot in the dark" I had his Wassermann reaction examined and found it +3. (The mother's and an only younger sister's were both -2. The father refused to come for examination.) I gave the patient no anticonvulsant drugs whatever, and treatment in the main consisted of three courses of bismuth ("bismogenol") separated by roughly six-monthly intervals. From the beginning of the second course no further fits developed. A subsequent W.R. gave a negative reaction. As it was difficult enough to keep up his attendances for injections I did not dare risk examination of C.S.F. About a year ago I heard from this patient regarding another matter and he has kept fit and well.

My suggestion is that Dr. Milligan's case sustained a spontaneous remission from the *symptomatic* fits of congenital syphilis (fits of all kinds, organic or idiopathic, often remit in a mysterious way), but that juvenile general paralysis was a later tragic development which possibly could have been entirely prevented by correct initial treatment. Be that as it may, this interesting case fully justifies one of Dr. Milligan's main contentions—the necessity of an all-round psychiatric training for those who undertake psychological work of any kind.—I am, etc.,

Armagh, N. Ireland.

ROBERT THOMPSON.

Acute Intussusception in Childhood

SIR.—The article on acute intussusception in childhood by Drs. Brenda Morrison and Donald Court (April 24, p. 776) should be read by all surgeons and general practitioners, as it stresses the extreme importance of early diagnosis and that once the condition is suspected admission to hospital should never be delayed. My last two cases arrived over 24 hours old; both required a right hemicolectomy on account of gangrene, and fortunately they recovered.

There is one important aetiological factor which I did not see mentioned in the article, and furthermore I am unable to find any reference to it in current textbooks of surgery or in those dealing more particularly with the surgery of childhood—that is that in every case upon which I have operated there has been present an extremely mobile caecum and ascending colon, which together with the terminal ileum were on a long mesentery. Normally, the terminal 1-2 in. (2.5-5 cm.) of ileum, the caecum, and ascending colon lose their mesentery during embryonic life and become fixed to the posterior abdominal wall, but in some 15-25% of individuals the old embryological mesentery remains, leaving an extremely mobile gut. The condition, which is slightly more common in females, predisposes to distortion, displacement, or rotation of the caecum and attacks of pain in the right iliac fossa, culminating in some cases in a volvulus (v. Gardiner, R. H., *British Medical Journal*, 1947, 1, 83).

That intussusception is largely confined to healthy first-born male children has not been my experience, as several of my cases

have been female infants. The change of feeding to a more solid form of diet at the weaning age of 6 to 9 months produces more powerful peristalsis, which fact, coupled with a mobile caecum, is in my opinion enough to initiate the intussusception. It is difficult to see how a fixed bowel can easily intussuscept.

At operation I agree that reduction should take place inside the abdominal cavity as far as possible, but it is the last "bit" which is always the most difficult to reduce. It is, however, easily delivered outside the abdomen, owing to its mobility, through a para-umbilical incision, without the trauma and shock associated with evisceration. This renders the final steps of the reduction much easier. Furthermore, if unfortunately resection and right hemicolectomy are necessary, due to gangrene, the presence of a mesentery to this part of the bowel makes mobilization an easy matter. The use of pressure enemata is an extremely dangerous procedure for two reasons: first I have known one case end fatally during the administration of the enema, and, secondly, it is impossible to tell if the intussusception has been completely reduced.

Timely diagnosis followed by careful preparation and skilled surgery are the only sure and safe measures to be employed for this serious emergency of childhood.—I am, etc.,

Aylesbury, Bucks.

RALPH H. GARDINER.

Antihistamine Drugs

SIR.—Your leader on histamine (May 8, p. 887) comments on Southwell's negative results with "anthisan" published in the same number. You seem to be much impressed by the use of inactive control tablets, and you appear to think that this in itself guarantees a true result. But this, I submit, is not the case. The control experiment can have this result only if the drug which is tested has been given in an effective amount. For instance, if, say, 1 minim of adrenaline were given to asthmatic patients, and 1 minim of physiological saline as a control, I am sure one would obtain results similar to Southwell's: some of the patients would improve remarkably with saline, whilst some of the others would get worse. Before beginning such an experiment with dummy controls one must try to find the optimal dose of the drug in question, and this can be done only individually. Unfortunately Southwell has made no such attempt, but has given the same dosage to all patients. This dosage was rather small (0.1-0.3 g.), and in addition was given over long periods in three or even four daily doses. I have found that this may cause tolerance and therefore give false results. The fact that drowsiness has been noted in only 10 out of his 42 patients makes it very probable that the dosage was insufficient. In my cases (*Lancet* May 1, p. 677), the optimal dosage was nearly always accompanied by drowsiness.

Another serious source of error is the assessment of results according to the patients' reports. Everybody who has tried to define with chronically asthmatic patients what they regard as "an attack" knows that their conception varies enormously. In most cases they are not sure where the chronic wheeze ends and the "attack" begins. If the condition is to be assessed over a long period the violent fluctuations which occur and which may not be influenced by any drug may render any assessment still more hazardous. There must be an additional objective measurement. The vital capacity is the only such measurement I know of, and it has proved to various authors and to myself a reliable standard. For instance, Curry (*J. clin. Invest.*, 1946, 23, 785) has shown that by varying doses of histamine different degrees of bronchial spasm and exactly proportionate decreases of vital capacity could be induced.

It is quite evident from my own experiments (which probably were not known to you when your leader was written) that anthisan does not benefit all asthma patients. Not all of them tolerate sufficiently large doses, and in a severe attack no dose seems to be large enough. But in a moderate degree of bronchial spasm it is often effective. If a really objective method is used, for instance intravenous injection, whilst the respiration of the patients is recorded by the spirometer and by the thoracograph of Verzar, the results can be relied upon. I have recently given doses of 0.05 to 0.1 g. in 10 experiments with 7 cases of asthma who were in a moderate asthmatic state. In 7 of the 10 experiments a striking increase (between 380 and 2,000 ml.) of the vital capacity occurred within 5 to 15 minutes. These increases could not be obtained by injections of physiological saline or glucose.

The mode of action of the antihistamine drugs, many more of which will appear in the near future, is full of problems. Their dosage varies more than that of other drugs, and the way

in which tolerance is acquired is obscure. With some of them it is difficult to find two patients who react to the same dose in exactly the same way; this holds not only for the antihistamine drugs proper but also, to a certain extent, for other substances with partly antihistamine action, like ephedrine and adrenaline. To mention only two of the many unexplained facts—why does anthisan, when given intravenously, require as long as 5 to 15 minutes until it acts? And how are we to explain that if ephedrine, "benadryl," or anthisan are given in one dose daily some of the side symptoms disappear after one or two days while other effects stay almost indefinitely?

Obviously these are very complex problems, and the question of the efficacy of these drugs cannot be solved by the use of dummy tablets and the reports of the patients. For this reason I feel that the conclusions in your leading article are premature.—I am, etc.,

London, W.C.1.

H. HERXHEIMER.

Penicillin Treatment of Scarlet Fever

SIR,—An outbreak of this disease in a large institution afforded an opportunity on a small scale of trying the method of treatment advocated by Dr. Torben Jersild, of the University of Copenhagen (Feb. 14, p. 318). Before seeing this report, 11 of the 79 cases had been treated with sulphanilamide with unsatisfactory results, inasmuch as three had unfavourable features. One had double antrum inflammation, another cervical adenitis, and the third went home after four weeks still harbouring the haemolytic streptococcus A in nose and throat and continuing to show positive swabs until nearly eight weeks from the commencement of the illness. Penicillin intramuscularly, as a snuff, and as pastilles caused a rapid disappearance of all symptoms and of the haemolytic streptococcus in the other two cases.

The remaining 68 had penicillin as recommended by Dr. Torben Jersild—100,000–150,000 units intramuscularly, twice a day, for six days. Not a single complication of any kind occurred, except in one case a penicillin rash was seen on the third day and treatment was stopped. It also had no effect in preventing recurrence of scarlet fever, for two cases had the typical rash and slight sore throat 3–4 weeks after the first attack. Penicillin treatment for three days resulted in negative swabs on the eighth day. Sixty-two gave negative nose and throat swabs when tested on or about the eighth day after the rash. Positive swabs were obtained in the six other cases; five became negative after about 14 days with further penicillin treatment for three days. One failed to respond until 24 days later, when very few haemolytic streptococci were found. A prolonged and intractable acute tonsillitis a few months previously may have been responsible for this poor result.

Most of these might safely have returned to the institution after eight days; but as it was winter a period of two weeks' isolation was adopted, and a further week for convalescence. The advantage of a shortening of the time lost through illness appears to be counterbalanced only by the objection that patients so treated may show penicillin sensitization at some future date. Rapid relief of sore throat was noticeable in all cases, and the general health excellent.

I am greatly indebted to Dr. D. D. Payne, the Medical Officer of Health, and Dr. J. Colbeck, County Pathologist, for their kind and helpful co-operation.—I am, etc.,

Harrogate.

R. F. CAMPBELL WARD.

Diagnosis of Periarthritis Nodosa

SIR,—The two cases of periarthritis nodosa described by Dr. J. M. Sutherland (May 1, p. 832) again bring out the difficulties of diagnosis. As Dr. Sutherland states in the section on diagnosis, "The possibility of periarthritis nodosa should be borne in mind in a case presenting multiple symptoms referable to several systems." Having arrived at this stage in the differential diagnosis, the problem arises as to how to clinch the diagnosis. The means of doing so fall into two groups, (a) histological section of a node or piece of muscle, and (b) visual evidence.

As regards the latter, Dr. Sutherland mentions only the ophthalmoscope, but there is another way, and that is visualization of the lesions through the peritoneoscope. Involvement of the mesenteric vessels is common in this condition, and it is easy to visualize the nodes on these vessels through a peritoneoscope. The procedure can be carried out under local anaesthesia with a minimum of disturbance to the patient. Dr. Sutherland's first patient had abdominal pain, and the necropsy in Case 2 revealed involvement of the vessels of the small intestine. It is almost

certain that Case 1 would have shown mesenteric involvement. I have described the visualization of the condition by peritoneoscopy in an article in the *Medical Press* (1947, 118, 487).—I am, etc.,

Leicester.

A. P. M. PAGE.

The Problem of Caries

SIR,—I have recently had the opportunity to read the annotation (April 10, p. 697) on "The Problem of Caries." Since you call attention to the researches of Pincus and Frisbie, which supposedly support the concept that the destruction of the enamel organic matrix is the initial caries lesion, it seems opportune to point out some of the recent evidence supporting the more widely held view that surface enamel acid production is directly related to the caries process.

In our laboratories we have made the observation that following the ingestion of refined carbohydrates the glucose (reducing substance) content of the saliva may show an immediate elevation to values in excess of 1,000 mg.%. This magnitude, depending upon the eating habits, characteristics of the food, etc., may persist in certain instances for periods as great as one hour. Stephan has demonstrated by *in vivo* methods that within two minutes after sugar solutions are ingested by caries-susceptible persons the pH of the tooth surface or within the carious cavity falls from approximately 7.0 to below 5.0. Such phenomena do not occur in caries-immune subjects.

The significance of pH values approximating 4.5 is not clearly understood. A variety of possibilities present themselves. They include: (1) This pH is critical for enamel decalcification. (2) This pH approaches the optimum for the activity of the acid phosphatase, an enzyme which has been demonstrated to be present in salivary bacteria by at least three investigators. (3) This pH approaches the optimum for many proteolytic enzyme systems, possibly for those present in organisms capable of producing caries. (4) This pH approximates the iso-electric point of the enamel protein, and the physical properties of this tissue may undergo marked alterations of importance in caries production. Any or all of these may be related to caries aetiology, but each depends on refined carbohydrate intake and bacterial acid production.

One fact seems indisputable—the diet must contain refined carbohydrates of the nature of starch, sucrose, or glucose if we are to produce experimental caries in animals. The Syrian hamster has been studied extensively by American investigators since 1942. I am aware of no single instance in which experimental caries has been reported as being produced with diets devoid of these materials. Fortification of these experimental diets with so-called protective factors has been a most ineffective caries-control measure.

It also seems pertinent to mention that the most extensive caries-control measure being used in the United States to-day is the topical application of fluorides. These have been shown repeatedly by controlled clinical studies on human being and animals to reduce dental caries by slightly in excess of 40%. Laboratory researches indicate that the application of topical fluoride results in a union of fluoride with the mineral phase of the enamel, reducing its solubility by approximately 50%, and enhancing its surface hardness. It seems more than coincidental that a substance affecting acid solubility should limit dental caries.

One cannot resist the temptation of suggesting that the most unsatisfactory aspect to research in the field of dental caries has been the constant unscientific criticism of our endeavours by many medical colleagues. In general, these gentlemen refuse to accept the view that the aetiology of tooth decay may not be comparable to that of other diseases. Such an attitude is discouraging, but understandable when one remembers the reluctance with which such fundamental disease concepts as bacterial infection, virus infection, and vitamin deficiencies were adopted.—I am, etc.,

Tufts College Dental School,
Boston, Mass.

J. F. VOLKER.

The Process of Ageing

SIR,—No doubt treatment of ovariectomized rats by various sex hormones and thyroid, as described by Dr. V. Korenchevsky (April 17, p. 728), represents valuable research work on relations and interactions of different endocrine glands and on their consequences to the metabolism of other organs, but it must be emphasized that ovariectomy itself does not produce the same effects as the physiological process of growing old in spite of certain features in common—for instance, in both cases

basophilic cells of the anterior lobe are increased and gonadotrophic hormone secretion is augmented. Loss of weight of organs can be caused by other endocrine glands or by changed influence of the hypothalamic, supraoptic, and paraventricular nuclei, and is not a symptom just of old age.

A certain difference of the body's reaction to castration and to growing old should be expected, because at the former fully functioning ovaries are suddenly removed from the system, but in the latter ovarian activity slowly has ceased, together with the loss of the ova. Further, a woman ovariectomized at the age of about 35 may live fifty more years, but a woman of 70 certainly not. Characteristics of old women, such as senile skin changes, loss of hair pigment, and growth of beard, do not commonly occur after ovariectomy, especially not involution of the whole of the body (osteoporosis, etc.), nor the pronounced emaciation often seen in senile women.

After the menopause gradual shrinkage of the adrenal cortex occurs, its function becomes weaker, and the 17-ketosteroids excretion decreases. As a result of castration, however, hypertrophy of the cortex, at least in some species, is observed. Especially in the male and in older female animals the hypertrophic phase may continue. Unlike what happens in old age, hypertrophy of the thymus occurs after castration in adult rats. Among eunuchs in Oriental countries there have been men of high intelligence who led long and active lives. Variations in fat metabolism and muscular weakness are due to individual differences in the influence of the hypothalamic centres. On the other hand, spermatogenesis is not unknown in old men of 80 or more, in spite of obvious signs of senility.

All experimental operations such as hypophysectomy, thyroidectomy, adrenalectomy, or gonadectomy have far-reaching consequences on the entire endocrine system, on the diencephalon, and on general metabolism. But the changes brought about are very different from the physiological process of ageing, which depends on two factors. (1) The life cycle and lifetime of cells of different tissues are different, and determined according to specific physiological needs. Relatively, the adrenal cortex begins to diminish in size in late embryonic life, but its extreme involution is significant of senescence. Involution of the thymus, of the pineal gland, of the gonads, and finally of the anterior lobe takes place during particular stages of life. The latest "natural" involution seems to be that of the vital nerve centres in the medulla oblongata. With this sequence the process of ageing is a very gradual one. (2) The whole endocrine system, which is of decisive importance in the ageing process, itself depends on the nervous and chemical function of the diencephalon. Because of this physiological relation all hormone therapy of ageing remains restricted within certain limits. As yet we do not know how to control and influence diencephalic activities either by chemical or physical means.—I am, etc.,

London, N.W.3.

HANS BAB.

Medical Photography

SIR.—Having spent much more time and money than I could afford on clinical photography, but without any regrets, I would nevertheless endorse the views of Drs. Francon Roberts (March 13, p. 485) and James F. Brailsford (May 1, p. 855). The hospital photographic department is an absurdity based on a misunderstanding of the function of art in medicine; or would anybody propose the employment of a biographer to take case histories?

For the clinician must take his own photographs if they are to be of any value to himself or of any use to his students; and the hospital need only provide a studio, some non-mobile equipment, and the part-time services of a technician for processing. Every university, however, should have a department for medical photography in order to provide instruction and advice on technique and to facilitate research.

The reason for the present exorbitant demand for ancillary services should be clear enough. The prudent householder uses all the electricity he possibly can in case his present consumption becomes the basis of rationing—and will not our new masters echo the cry of those who put them in power, "Never had it before, Doctor"?—I am, etc.,

Manchester.

J. H. TWISTON DAVIES.

SIR.—Dr. J. F. Brailsford (May 1, p. 855) is of course entitled to his opinion that there has been no improvement in medical photography during the past forty years, but it would be strange if this branch had stood still while all others have progressed. I cannot help but suspect a *laudator temporis acti*.

To mention names would perhaps be invidious, but it would be nearer the truth to say that while there do exist many excellent illustrations in the literature, the great bulk of pictorial work is mediocre. Blaming the editorial boards will not help if the material is not good in the first place.

The scorn which Dr. Brailsford pours on the figures quoted in his last paragraph would have borne more weight had he told us whence they emanated. There are two main reasons why output has risen, apart from the demand for teaching. First, the supply of material is improving; this held down availability in preceding years. Secondly, more uses are being found; in the control of the growth of visible tumours, for example, a controlled scale print is much less liable to error than the more usual outline sketch, and in a properly organized department is not only more accurate but actually time-saving. The photograph is free from any possibility of personal error, which may well change with the observer.

An Exhibition of Medical Photography sponsored by the Medical Group of the Royal Photographic Society is to open at the Royal Society of Medicine on May 24. May I suggest to Dr. Brailsford that he permits the committee to exhibit some of his forty-year-old illustrations? Even allowing for any deterioration of the prints due to age it should be most instructive to compare them with present-day work.—I am, etc.,

Manchester, 13.

ROBERT G. W. OLLEPENSCHAW.

Treatment of Pruritus Ani

SIR.—Dr. Alexander Orley, in his letter on the treatment of pruritus ani (May 8, p. 904), tends to indicate that in Guernsey the aetiological factors of this troublesome condition differ greatly from those which obtain in most other parts of the world. He states, "The variety of methods of treatment and the frequent therapeutic failures in pruritus ani are probably due to a lack of recognition of the fundamental cause of the complaint." This is exceedingly true, but surprisingly enough he then proceeds to remark, "This cause, however, is always the same. It is the exposure of the perianal skin to particles of faecal matter." In his series of about 50 cases he does not seem to have encountered some of the most common causes of pruritus ani, such as asthma, eczema, yeast and tinea infections, nor any of the others not infrequently discovered, such as threadworms, amoebiasis, lichen planus, gonococcal proctitis, etc.

He remarks that it usually occurs in middle and old age, more seldom in young individuals, and practically never in the young and adolescent. Of 107 cases seen by me in 1946, 19 patients were aged between 21 and 30; 32 between 31 and 40; 13 between 41 and 50; and 21 between 51 and 60 years of age.

Undoubtedly x-ray therapy is, as he says, extremely useful, but it has the great disadvantage that the patient obtains so much relief from it that should a relapse occur he is apt to importune the doctor for further treatment, and only those who have seen a number of pruritus ani patients with a complicating radiodermatitis can know what this combination means.

Finally, he remarks that a combination of x-rays and anal hygiene has been uniformly successful in over 50 cases, but it is to be regretted that he does not state what period of time he has chosen as the criterion for a cure.—I am, etc.,

Edinburgh.

G. A. GRANT PETERKIN.

Unusual Inguinal Hernia

SIR.—In March, 1948, an African male aged about 35 years was admitted to Cape Coast Hospital. He stated that he had had a swelling in the left groin for four years. It was difficult to make out from his history whether the swelling had been self-reducing or not. Three hours before admission the swelling had increased in size, become painful, and he had vomited twice.

On examination there was a tender, tense, irreducible swelling about the size of a tangerine in the left groin, with slight protrusion through the external inguinal ring. There was no cough impulse. The condition was diagnosed as strangulated left indirect inguinal hernia.

Under hypobaric "peraine" spinal anaesthesia the diagnosis was confirmed. The hernial sac contained a loop of very congested but viable small intestine. The strangulation at the internal ring was

relieved. All attempts to reduce the gut to within the abdominal cavity failed, though a finger could easily be passed through the internal ring. A sudden subserous haemorrhage into the gut wall, stripping up the serous coat for several inches, made resection of about ten inches of gut with end-to-end anastomosis necessary. It was easy to draw down additional gut to perform the resection wide of the injured area.

Again attempts to reduce the remainder of the loop of gut failed. Laparotomy through a low left-paramedian incision revealed the reason for this inability to reduce the intestine to within the peritoneal cavity. About three inches above and internal to the internal inguinal ring there was a narrow-mouthed pouch formed by the posterior parietal peritoneum, through which the intestine passed. This pouch expanded downwards and outwards into a wide serous-lined cavity, which narrowed as it passed through the internal inguinal ring and was prolonged into the inguinal canal as the hernial sac. The abdominal mouth of this long serous-lined cavity was narrow, and, though firmly holding the loop of small intestine, was not causing strangulation. By pulling gently from above and pushing from below the gut was easily returned inside the peritoneal cavity. The abdominal opening of the sac was ligatured and the abdominal and hernial wounds closed. The patient's condition caused some anxiety for the next twenty-four hours, but subsequently recovery was rapid.

I am indebted to the Director of Medical Services for permission to publish this case.

—I am, etc.,

Cape Coast, Gold Coast

A. F. FOWLER.

Waiting for Tonsillectomy

SIR.—It is certain that the waiting-lists for admission into hospitals of children needing tonsillectomy and adenoidectomy have now reached such proportions that a desperate position has arisen. As many of us know from personal contact with the parents and reading their letters, their anxiety about the health of these youngsters is leading to acute distress; whilst to doctors whom they have consulted and who have advised the operation—often marking their notes, "Needs very early operation"—this state of things has become intolerable.

Both parents and medical advisers see the steady deterioration in these children, and just at a time of life when it is of the utmost importance that healthy growth should be encouraged and not hindered, with all the serious complications that may reasonably be feared.

I cannot see that this problem is insoluble, nor that its urgency is not obvious, and I sincerely hope that this letter will stimulate response and lead to action without delay.—I am, etc.,

London, W.1

WILLIAM IBBOTSON.

Advantages of Impure Penicillin

SIR.—In relation to the annotation entitled "The Advantages of Impure Penicillin" (April 24, p. 795), in which it is stated that it has been suspected for some time that the imperfectly purified penicillin of earlier days was more effective than the refined present-day product, and that recent experiments show conclusively that in the purification of penicillin something unknown and valuable is lost, I would mention that this conclusion was arrived at by co-workers and myself in this hospital in early 1944.

In this pioneer work aseptic pyrogen-free penicillin filtrate injected intramuscularly in human beings was followed by recoveries and clinical effects in fulminating diseases such as subacute bacterial endocarditis and meningitis which could not possibly be accounted for by the penicillin content of the filtrate, thus suggesting some potent unknown factors, probably both antitoxic and antibacterial, and immeasurable by known methods. I am not, of course, advocating a return to the filtrate, but it would appear that a wide field for further research lies open in that direction.

Unfortunately our results were not published, presumably—and possibly quite rightly—on the grounds that the idea appeared in those early days too far-fetched to be put forward as a scientific theory.—I am, etc.,

Wellhouse Hospital, Barnet, Herts.

H. R. SEGAR.

SIR.—With reference to the annotation entitled "The Advantages of Impure Penicillin" (April 24, p. 795), I beg to point out that I arrived already in 1944 at the conclusion that "in the purification of penicillin something unknown and valuable

is lost." Together with W. K. S. Wallerstein I wrote, "The effects of this suspension, in addition to the penicillin effect, are due to the presence or production of other potent bacteriostatic compounds—which are destroyed or left behind in the manufacture of penicillin" (*Nature*, 1944, 153, 380). The suspension referred to was the product "vivacillin." Preliminary animal tests with this product had been carried out by E. v. Lustig-Lendva (*Vet. Rec.*, 1944, 56, 178), whilst Dr. R. Segar, Medical Superintendent at the Wellhouse Hospital, Barnet, was the first one to submit the product to clinical tests on a large scale at his hospital.—I am, etc.,

London, N.W.4.

H. ENOCH.

Viennese Twilight

SIR.—I have received from my publisher, Heinemann and Co., London, your review (Jan. 17, p. 103) of my book, *The Art of Healing*, and I feel that this criticism should not go unanswered, as it misrepresents the whole tendency and contents of my book and misinforms the British medical profession as well as the general reader. At a time when the British medical profession is in such a predicament that a large part of the nation is disappointed enough with its accomplishments to want to make the physicians servants of the State, the medical profession should consider whether it is not itself responsible to a large extent for this shameful situation.

Those among British physicians who are not "isolationists," as the reviewer of this book, may know that in Germany and in France medical thinkers, including this author, have spoken during the last decades of a very serious "crisis in medicine," which was brought on by overemphasis of "hyperexact" detail work, over-specialization and laboratory medicine, and by neglect of the practical, erroneously called "empirical," methods of pre-Virchowian medicine, thus making the practice of medicine too fussy, complicated, and expensive. In England itself it was mainly outside of the medical profession that this harmful development was recognized. Bernard Shaw's *Doctor's Dilemma*, despite its satirical exaggerations concerning the overemphasis of the so-called "scientific," bacteriological, and surgical trend, is still valid to-day. A. Flexner, the emissary of the Rockefeller Foundation in America, has sufficiently exposed in his famous reports on "Medical Education" and "Universities" the superficiality of the present British trend.

There are in fact two principal approaches to theoretical and practical medicine. One—and this is the prevailing doctrine in England and some other countries—denies the value of the methods of our medical predecessors and looks for salvation in present and future new discoveries only, stressing at the same time the allegedly "exact" (auxiliary) natural sciences such as physics, chemistry, anatomy, experimental physiology, bacteriology, etc., while discarding all the methods (of medicine proper) of proven practical value which have been collected by earlier successful physicians from antiquity up until 100 years ago.

The second trend believes that, even more than any other science and art, medicine (which is not an exact science but collected experience) must be founded on the best of the practical therapeutic methods of the past. All the pious talk about Hippocratic ideals and Hippocratism becomes pure lip service and nonsense if we sneer at such fundamental and indispensable methods of general care as the depletion, antiphlogistic, antidyscrasic, tonic, antispasmodic, and other methods, which include properly indicated purging, sweating, bleeding, venesection, cupping, leeches, vomiting, and the utterly neglected counter-irritation.

The Constitutional Doctrine is itself divided into these two principal approaches to medicine. Julius Bauer, the author of *Constitution and Disease*, whose fatalistic philosophy is praised so highly by the reviewer of my book, is a follower of the former hyper-rationalistic, dogmatic, and hyperexact trend of dialectic materialism, which has led medicine to scepticism, therapeutic nihilism, and unnecessary incompetence in many fields. According to Bauer, constitution must be identified with heredity and therefore cannot be influenced by therapy.

On the other hand Hippocrates and all his followers, including Sydenham, Hunter, Heberden, Hufeland, and in modern times Friedrich Kraus (Berlin) and F. Martius (the original founder of modern constitutional doctrine), do believe in the possibility of influencing human constitution by therapy. I myself tried to put this endeavour into practice by combining the discarded but valuable fundamental methods of the past with modern medical standards. Scientific evidence in my *Textbook of Constitutional Therapy* (Hippocrates Verlag, Stuttgart, 7th edition, 1934). As this attempt was new, at least in our time, I tried to bring it into a teachable system and called it constitutional-therapy, an accomplishment which was given credit by the noted medical historian Dr. H. E. Sigerist,

Johns Hopkins, Baltimore, in a review of the American edition of the same book ridiculed by your reviewer. I am enclosing a copy of Sigerist's review. As Sigerist suggested that I should prove my claims in a more specialized field I published in 1946 a monograph *Treatment of Arthritis and Rheumatism in General Practice*, New York, 1946, which was warmly accepted by a large part of the American medical press (reviews enclosed). For more than 20 years I have been able to demonstrate in my clinical and private practice that the large majority of all cases of arthritis (which is osteoarthritis) can be greatly improved or completely cured in a relatively short time by these very methods of historical tradition, particularly the various forms of alteration, elimination, and counter-irritation. As is known, the treatment of arthritis is a stumbling block of modern medicine which cannot be overcome by the present allegedly "exact" and "rationalistic" medical methods.

The same applies to the treatment of stomach ulcer, gall-bladder, and kidney diseases, skin conditions, menstrual disorders, conditions of the menopause, etc. The reviewer gives fun at emetics as the means of treating schizophrenia. If he would have read the classics of the 17th, 18th, and early 19th centuries (not to speak of Hippocrates, Galen, and his followers until modern times) he would have found out that vomiting is one of the oldest, simplest, and most effective forms of shock-treatment. I have published a whole monograph on this subject in 1933, and I can prove daily the truth of this statement. Incidentally a member of a noted family in London who had been suffering from schizophrenia for many years and could not find any relief by the usual routine treatment was so greatly improved within three months last year by emetics, drastic laxatives, and hydrotherapy that he lost his spells of catatonia and maniac outbreaks and became self-controlled and sociable.

The reviewer also ironically devalues the vital importance of a regular menstrual flow for feminine health. The frequently devastating and unpredictable consequences of premature artificial menopause (brought on by indiscriminate hysterectomy or radiocastration), known to any unprejudiced observer, sufficiently refute the reviewer's remarks.

The reviewer of my book also does not believe in the diagnostic and therapeutic significance of the coloration of hair, eyes, and skin. In this respect earlier physicians and modern homeopathic physicians have much more broad-minded views. That the confidence of the public in the present form of scientific medicine actually is shattered to a large extent cannot be doubted by anyone who opens his eyes. The numerous sectarian and "eccentric" trends are only an inadequate reaction to this situation. The true scientific remedy is, as mentioned above, the combination of the erroneously discarded practical methods of the past with modern diagnosis and technique. If the reviewer does not want "to return to the mediæval mess of leeches, purges, emetics, and clysters" (to which venesection and other methods mentioned above must be added), he deprives practical medicine of nine-tenths of all effective, sometimes even life-saving, therapy which is still principally "empirical" and will be so for a long time to come, if not for ever.

These are not mere theoretical speculations but facts proved by the author and his followers in various countries for more than 20 years by the cure of just those patients which laboratory medicine has failed to heal.—I am, etc.,

New York.

B. ASCHNER.

Health Centres

SIR.—Now that the graver differences between the profession and the Minister have been resolved and the Act will in due course come into force, it may perhaps be appropriate to raise again the question of the health centre as the base of operations for the family practice of the future. The concept and purposes of the health centres have been widely accepted and approved, and one of the greatest disappointments, alike to the supporters and disputants of other main provisions of the Act, was the recent intimation from the Minister that there was no hope of early action in respect of them. Perhaps, however, we need not despair unduly and pressure may be brought to bear upon the Minister to consider at least certain important priorities.

There are, for instance, some cities, which have given particular attention to matters of health centre design and staffing, in which earlier action and the building of the first experimental centres might, for good reasons, be sanctioned. But there is one case which calls for special consideration—namely, that of the health centres to be established in close geographical proximity to, and close spiritual relationship with, the teaching hospitals. Well planned and adequately staffed with practitioner teams of appropriate experience and age constitution and the necessary ancillaries, and given responsibility for the ante-natal and maternity and child welfare work of their locality, these centres could and should become an integral part not

only of the public service but also of our evolving patterns of educational establishment having as their main concern the training of medical students and the advancement of knowledge. The staffs of such centres, given proper regard for age, training, and competence, should hold status comparable with that of the teaching-hospital staffs.

With reciprocal interest as between such centres, the clinical departments of the hospital, and university departments of social medicine (where such are in being), (a) the training of the young doctor, and (b) socio-medical inquiry in the domestic sphere could both be greatly assisted. Some of us would eventually like to see apprenticeships in approved health centres becoming statutory during the first post-qualification year and accepted as having an importance not less than that of house appointments. Here for the first time the young graduate would obtain his experience of the patient in relation to his family, his living conditions, and his work; of the varied methods and problems of family practice; and of a personal health service (especially for mother and child and adolescent) as distinct from a purely sickness service. Here, too, better recording systems, more intimate collaborations between the practitioner, the hospital, and the officers of the public health authority, and new economies of time and labour in family practice could be given their first trial. And finally, with the advantages accruing from improved relationships and new responsibilities, these health centres could come to set the standards which would ultimately be expected of other centres more remotely situated. The practice of social medicine at the family level would, in fact, have a chance to start off "on the right foot."

The first essential for an improved practitioner service, and one which has never received enough official emphasis, is a very great improvement in the conditions under which the doctor works, in his equipment, and in his sense of association with other branches of professional activity.

Will the Minister reconsider his late pronouncement in favour of urging the early design and building of health centres to work in suitable areas not too distant from each of the medical schools of the country and in intimate association with them?—I am, etc.,

Oxford

JOHN A. RYLE.

Full-salaried Service

SIR.—The B.M.A. is to be condemned for permitting the profession to fall between two stools. We are thus faced now with the bad points of both systems. The senseless overwork of the competitive system remains, but we fail to gain the benefits of the nationalized service—adequately staffed health centres and fixed hours of duty—which would put an end to the endless drudgery of general practice.

Furthermore, we now find that the B.M.A. is not able legally to act as a trade union, and in a nationalized service the need for such a protective body is glaringly necessary, and the sooner the better.

It is easy to be wise after the event, but it is obvious either that the B.M.A. should from the start have resisted all attempts at nationalizing the profession, or, having admitted the desirability of such a scheme (which it did admit), it should have sponsored a completely socialized whole-time salaried service with the abolition of private practice. For this is the only method of providing the public with adequate medical attention at all times and, at the same time, providing the doctors with fixed hours of duty. (It would of course also remove the antisocial vested interest in ill-health, as Bernard Shaw has pointed out.)

We general practitioners are agnostic at the prospect of the added work ahead of us for ourselves and our households, necessary maybe from the insurance point of view, but not necessary from the health aspect. Because of division within our ranks, our own undecided leadership, and by financial blackmail, Mr. Bevan has continued to "swing" it on us, without even the provision of health centres, the *sine qua non* of the general practitioner's compliance. The only result possible is an unsatisfied public, because there will be even less time than at present to give to the real sick, and a grossly dissatisfied profession because of added unnecessary work. Already we know only too well how we are forced to wear ourselves out not by attending the sick but rather by all the extraneous matter which force the populace to flock to our doors.

To those general practitioners who do not like the word "salary" it will be necessary to point out that in a socialized service the country would be divided into districts serviced by the requisite number of doctors, and the capitation fees would be pooled and divided. The older doctors may feel that as they grow older they should be entitled to more money, but in actual fact, because of their age, their need is less work rather than more money, especially as in a pensionable scheme the need for the latter is provided for. It is indeed the younger men who are in need of larger incomes—with families to feed, clothe, house, and educate, whereas the families of the old doctors would presumably be grown up and self-supporting, and there would no longer be the need to be over-housed with the advent of the health centre.

Now that a socialized service is upon us our needs are for less cant, hypocrisy, and sentimentality (such as goodwill, doctor-patient relationship, etc.); more understanding of present-day realities; and the formation of a strong trade union with strong leaders who will not throw up their hands in horror at mention of a "paper" strike. The "paper" strike will in fact be the only weapon of defence against any Government both on our own behalf and the behalf of our patients—should negotiations fail.

When the profession realizes—as it will in time—that the majority of patients will be "panel" patients I venture to think that it will see not only the advantages but also the necessity of a completely socialized service with its health centres and fixed hours of duty. These are two of the primary points which the general practitioner should be fighting for now—and the specialists too if they are not given them.

Now that we are committed to this scheme we might as well begin by fighting for the good of both worlds—our own as well as that of our patients. (It might be as well too to point out to them the fact, which few patients seem to appreciate, that we doctors do have our own worlds apart from them.) Just as few patients show more than passing concern of the fact that we may be working night as well as day, so we need expect no Government to be interested in our conditions of service unless we fight for them ourselves through our own trade union and the Housewives' League.

May our leaders, at this eleventh hour, be granted an understanding of present-day doctoring. Changing conditions need changed methods. Much good will be lost from the old, we know, but in compensation we have also lost much harm.—I am, etc.,

Englefield Green, Surrey.

W. E. R. BRANCH.

Terms of Service

SIR,—There is a general impression that the financial terms offered by the Government under the new national health scheme are fair and even generous. This has been stated over and over again by the Press, by Government supporters in Parliament, and even by the leaders of the Opposition. When the public reads that a doctor with 4,000 health service patients will receive £3,332 per annum, it does sound that doctors would be generously paid, and even many general practitioners are under that impression. Actually the reverse is the case and the payment offered is miserably inadequate.

There are about 20,500 general practitioners in the country, and the population for which they may provide medical treatment is about 47,750,000. Excluding the considerable number who will not avail themselves of the new Health Service, including Christian Scientists and followers of one or other of the numerous unorthodox medical cults, the numbers left to the orthodox medical practitioner cannot be many more than 2,000 a head. Many practitioners will have less, and very few can reach the maximum of 4,000, with a gross income of £3,332. Two thousand patients is probably the average a doctor has at the present time, and if he has a fair proportion of infants, young children, and old and chronic cases this is at least as many as he can look after properly without being over-worked, unless he lives in one of the densely populated districts where all his patients live within half a mile of his residence and can be rapidly and speedily visited on foot.

With 2,000 patients a doctor's gross income under the new Health Service will be £1,816, but out of this gross income he has to provide at his own expense a sufficiently large house

with a surgery and waiting-room. He will have to pay a secretary and provide for the cleaning and heating, furnishing, and decorating the premises. He will have telephone and postal expenses, and to provide and maintain for his professional use at least two cars in a rural or semi-rural district, so that one is always available. He will have to provide and maintain his instruments and medical library. If he goes on holiday he will have to pay a locumtenent about £15 15s. a week, and to supply him also with board and lodging and motor-car expenses.

If he is ill he also will have to arrange for a locumtenent. He will still have to be available to all his patients 24 hours a day and 365 days a year, or provide and pay a deputy. He will have to provide attendants for the door and telephone day and night. As his maids and secretary cannot be expected to be on duty for 24 hours a day, it follows that a doctor's wife takes their place when they are out, so that usually a doctor's wife has just as long hours of duty as her husband. Many doctors now are unable to obtain any domestic assistance. Before the war it was calculated that a third to a half of the gross income was spent in practice expenses. These expenses have all increased. This is especially the case with domestic wages, which have more than trebled.

Mr. Aneurin Bevan is offering less remuneration than that recommended by the Spens Committee. This is not generally realized. I hope our representatives are emphasizing this aspect of the new Health Service in their present negotiations.—I am, etc.,

Rainham, Kent.

DESMOND LONGFORD.

SIR,—At the Panel Conference last October, at which I was present, Dr. Dain stated in reply to questions: (1) That the Negotiating Committee had not discussed Regulations because they had not yet decided whether the profession was going to work the Health Service: (2) that they had not discussed compensation, as they had not accepted the principle of the abolition of the sale and purchase of practices.

At the time and ever since I thought it would have been better if the Negotiating Committee, instead of taking a stand on a platform of four ideological planks, three of which were rotten and have now been thrown aside, had got down to brass tacks. With a view to getting some of these tacks hammered out I have sent notice of four resolutions to my local branch of the B.M.A. which I hope will go up to the Representative Meeting:

(1) That any practitioner who has been practising midwifery prior to the appointed day shall be automatically entitled to take part in the midwifery service under the Act without applying to the Local Obstetric Committee, and that the Minister be pressed to alter the Regulations accordingly.

(2) That there shall be no alteration in the terms of service without negotiation with the accredited representatives of the professional bodies concerned, and that the Minister be pressed to include this in the Amending Act.

(3) That where a practitioner takes another practitioner into partnership he shall be entitled to receive forthwith the compensation for that portion of his practice transferred to the incoming partner.

(4) That where a practitioner leaves a practice to take up another practice elsewhere he shall be entitled to compensation for the practice he leaves forthwith.

I think these points speak for themselves, but I may add that my Local Medical Committee feel so strongly on the first point that it has refused to make any nomination to the Local Obstetric Committee.—I am, etc.,

SIDNEY F. FOURACRE,
Chairman, E. R. Yorks Local Medical
Committee.

Withernsea, Yorks.

The Young Doctor

SIR,—One reads in your columns of the acute shortage of general practitioners in the country at the present time. This surprises me, because one has only to look in the advertisements section of the B.M.J. to observe that there are frequently far more doctors desirous of purchasing practices or shares than there are wishing to dispose of them. At the same time the medical agencies say that good practices and even assistantships are very difficult to obtain. What, then, is the young doctor to do—particularly the newly released Service M.O.? These are the men whose pathetic advertisements constitute the main part of your "Practices and Partnerships Wanted"

MAY 22, 1948

columns. As a profession we are all passing through a trying phase now, but the young doctor, especially if he is married and is not yet in general practice, is in my opinion in a far worse position. He has no post (and he is quite prepared to start at the bottom of the ladder) and has no alternative but to enter the scheme, even though he may be opposed to it in principle. I do not wish to criticize my more experienced and older colleagues, but surely it is the young man now who will be the "backbone" of the profession in, say, twenty or thirty years' time, yet little is being done for him. In fact, the young man is left out of all the discussions, and what would possibly be his only means of support for some time—namely, the £300 basic salary—was one of the major points around which the acceptance or refusal of the scheme revolved. I feel that the younger doctor, particularly the ex-Serviceman, should be given every consideration by the B.M.A. in his quest to do the right thing. He cannot possibly do this while he and his wife go hungry. There are many who are only too willing to join the ranks of the profession and reduce the shortage of G.P.s but it is fast becoming increasingly difficult to do so. While their elders talk, the young men are simply registered medical practitioners, and very little else—I am, etc.,

G. J. E. ANSELL.

Go in Whole-heartedly

What has become of the determination not to enter the Service unless so amended as to allow entrants to retain their "four" freedoms? What leadership! What a let-down! So now, what to do? Obviously there's practically no alternative to going in. That being so, let us go in whole-heartedly, and since we *must* be Civil Servants let us have an all-embracing one. Let it be a salaried one, with graded salaries as in any other reputable service, graded by seniority and influenced by merit, with permission to indulge in private practice, if any, in our spare time, if any, and so one wherein the senior man may reap some reward for his experience and more valuable opinion as compared with that of the young just-qualified tyro in the profession. For surely a capitation method of remuneration, whereby the only way in which a more

competent senior man may make a sufficient scrabbling for more heads, is absurd and ridiculous. If it be objected that a salaried service would do away with the freedom of choice by the public, the answer is that if the public care so little for the freedoms of the doctors the latter need scarcely care about the freedom of the public. Further, since the Act is a totalitarian measure, freedom is abolished anyhow and need no longer be argued about, and since in a few years the role of the G.P. will be merely that of positive direction of a patient to the appropriate department of the general store of "trained specialists," whence he will again be directed to department and department—as long as he lasts—even the importance of freedom of choice will soon disappear, and all, save perhaps the patient, will be happy again.—I am,
etc.,
C. H. BAPPEE.

Refuse Service

E. D. BROSTER..

Postpone Appointed Day

It is difficult to see why the B.M.A. had another plebiscite at this juncture. The result has been deplorable. It strengthened nobody and only succeeded in splitting the profession and throwing large numbers of us into confusion and misunderstanding of the real purpose of the B.M.A.'s action. This was evidenced at a large meeting of medical men at Nottingham on April 25. It began with several doctors pleading that as Bevan had been so "good" as to meet us half-way we ought not to hold out any longer, but accept service. It ended with a unanimous vote (with only one dissident) against accepting service.

The last plebiscite has so far only played into Bevan's hands. It is just what he wanted—to split the profession, to throw them into confusion, to make them timid and afraid to stand out in case they should lose. He threatens them with severe penalties if they do not join in July—and to keep them in ignorance of the real facts of the situation as long as possible. We have only had our printed terms of service practically flung at us a fortnight, which will take a long time to read, digest, and discuss, thus hoping that out of the confusion we should fling ourselves at last into dear Father Bevan's arms like naughty penitent children, who had been so patient and kind in granting us one and a half of our four basic demands.

Bevan didn't give way because he loved us but because we forced him to do so when he saw 25,000 doctors pledged not to give service. Why stop now? Do let us show some of the grit which Bevan and his confrères show when they demand anything. Refusal to be rushed into the Service on July 5 does not necessarily commit us to accepting service at some later date. Don't let us act like "medical quislings" to our colleagues for fear of a little temporary gain. If we stand firmly together and decline service, we can't lose. We are bound to get what we want—i.e., professional freedom for ourselves and for the public. Don't sign in haste and repent at leisure. If Bevan beats us now, the profession will be beaten and degraded for ever. The public are being grossly misled by Bevan's present furious propaganda stunt.—I am, etc.,

Tuxford, Notts.

ALLAN DEWAR.

Postpone Service

SIR,—We voted "No" in February and frightened the Minister into making some concessions. If only we had voted "No" again just as decisively we should have frightened him into meeting all our reasonable demands. Instead of this we have been timidly retreating ever since last February as if scared by our success.

If the Council's recommendations are passed by the Representative Meeting we shall have thrown away our last vestige of bargaining power, and this at a time when the specialists' terms of service have not even been discussed. The Minister will negotiate, of course; but, with the sure knowledge that he has got the whole profession "in the bag," it must be obvious even to the most innocent doctor that it will be done in a manner even more intransigent than that of last December. Do let us realize that once G.P.s have signed on, or been recommended to sign on, the whole profession—specialists and G.P.s—will be completely powerless to influence him in any way whatever. The specialists will have had their hospitals taken over, the G.P.s will be bound by their contracts, and all of us rendered impotent by the stupidly publicized boast that "the doctors will never strike." Negotiations will be a misnomer for what will take place.

While it is now inevitable that we shall eventually have to accept service in the scheme, we must maintain some hold over the Minister until negotiations are complete. There is one way in which this can be done—a way which would satisfy the vast majority of the profession, and which could be accepted by the Minister without losing face. Let the Representative Meeting pass a resolution stating that doctors will be recommended to accept service provided the appointed day is postponed until the amending legislation has been agreed, passed, and become law; until terms of service for specialists have been agreed and settled; and until the other minor points (such as a definite, known capitation fee) have been arranged.—I am, etc.,

London, N.W.6.

RONALD KERR.

Delay Entry

SIR,—It would appear that one-half of the medical profession will be asked to relinquish conscientiously held vital matters of principle in order to facilitate an admittedly unsatisfactory start to a service which is almost universally disapproved. This is an unjustifiable concession to ask from this half of the profession. Though we cannot unite we can still co-operate and strongly support one another each in our own place.

I would suggest that all doctors unwilling to enter the Service as it is should agree to exercise their legal option to stop outside until Sept. 30. This would be of great assistance to the Negotiating Committee in keeping before the mind of the Minister the dissatisfaction of the profession. The general practitioners stopping outside would have the opportunity of bolstering up their courage—and encouraging the Minister—by collecting cards for registration on Sept. 30. The Minister would also have an opportunity to consider whether it might be useful for him to conciliate those intransigent doctors who may still be able to postpone their entry into the Service until Dec. 31.

We must give our negotiators some power to negotiate with: the profession is a useful lever. We can of course trust one another to play the game about accepting names for registration—and securing "no victimization."—I am, etc.,

G. D. FRASER.

H. D. FRASER.

Planned Chaos

SIR,—In these days of strange events a 65% vote of disapproval is interpreted by the B.M.A. Council as warranting a recommendation that we should now accept service. Thanks to our medical oligarchs and to the threat of financial sanctions it seems that orderly evolution in the British tradition must soon give way to planned chaos in the neo-European manner. The whole-hearted co-operation which could have been forthcoming in such full measure will be replaced by reluctant and apathetic acquiescence or by futile opposition. Unless there is a return to common sense at the eleventh hour many of us will apply to ourselves the adage *video meliora proboque, deteriora sequor*.—I am, etc.,

Hessle, E. Yorks

R. HERMON.

Rota of Pharmacies

SIR,—The British Medical Association has done a good job of work in connexion with the National Health Service Act and still has much to do. May we hope that in this coming task attention will be drawn to the need of patients' being able to obtain medicine at suitable hours? At present the pharmacies appear to close more or less at the same times as shops which do not supply urgent products. Can there not be a rota?—I am, etc.,

London, N.W.11.

L. S. WOOLF.

POINTS FROM LETTERS

Ante-partum Haemorrhage

Mr. W. I. C. MORRIS (Edinburgh) writes: Dr. Tim Boland (May 1, p. 859) comments upon the use of the vaginal pack in ante-partum haemorrhage, as reported in your summary (April 17, p. 748) of the Edinburgh Obstetrical Society's Meeting on March 10. On behalf of my friend and successor in Ayrshire, Dr. Richard de Soldenhoff, I would like to point out that the report (of which I blushingly admit the authorship) was extremely abbreviated. It is hoped that eventually a fuller report will be published in the *Edinburgh Medical Journal*. If Dr. Boland has an opportunity of reading this, it may be that his condemnation will be less indignant. To understand all is to forgive all.

Accidental Syphilis

Dr. M. G. KIERANS (Clones, Eire) writes: Dr. R. R. Willcox, in his interesting article on accidental syphilis (May 1, p. 850), mentions a number of ways it may be acquired. I should like to mention another. A policeman bringing a prostitute to the station is very likely to be bitten by her and so become infected. This happened to a patient of mine.

Self-government

A correspondent draws attention to the following after-dinner message of good wishes from Sir James Paget to the British Medical Association at its Jubilee meeting in August, 1882: "There has never been anything like a recession from the great principles on which it started. It has been constant in its steady advance; constant in its usefulness; constant in the influence that it has exercised upon the profession; constant, best of all, in the promotion of knowledge and good feeling amongst all the members of our calling. . . . I hold that our great anxiety, our great strife, should be, to be a self-governed profession; to know our own wants, and not to go to others to help us; to find out the remedies for ourselves; to find out by careful, patient controversy, and mutual concessions, how we may, without any external help, bring about the results which the best and the largest number of us wish for. Let us be, as all highly cultivated persons should be, self-governed. None can know so well as ourselves our need; none can know so well the remedy we require. It tells of feebleness, of cowardice, and want of self-reliance when we want to go to any parliament living to help us."—*Memoirs and Letters of Sir James Paget*, edited by Stephen Paget. London: Longmans, Green and Co. 1901. Pp. 320-1.

The April Plebiscite

Dr. A. R. THATCHER (Bournemouth) writes: . . . It is completely incomprehensible to me that in an unmandated plebiscite, rushed through on the strength of the capitation concession principally, a number of practitioners should have panicked. Do they not realize that the time to demand a 1948 remuneration—not the 1939 Spens offered by the N.H.S.—is before they enter the Service and not afterwards when they are in the power of the Government? I sympathize with the dilemma of those in strictly industrial practices, but would urge them to await the approval of the majority before throwing away their advantages.

Obituary

PROF. A. H. BURGESS, M.Sc., F.R.C.S., LL.D

Mr. John Morley writes: The Fellows of the Association of Surgeons of Great Britain and Ireland were greatly shocked when their president announced at the dinner of the Association on May 6 that Prof. Burgess had died suddenly after his arrival in Edinburgh for the meeting. Burgess's reputation among surgeons all over the world had been a remarkably high one for wellnigh forty years, and many of those at Edinburgh felt keenly the loss of a personal friend.

It was at Crumpsall that he made himself an expert in the use of the newly invented catheterizing cystoscope by assiduous practice on the cadaver. His senior colleagues and chief rivals in practice never mastered this instrument, and Burgess's remarkable skill in using it soon brought him the best urological work in Lancashire and Cheshire. Although urology was one of his main interests throughout his active surgical career, he never became a urological specialist but remained a supremely competent general surgeon. He had deserved early success and it came with a rush. At the early age of 31, in 1905, he was elected honorary assistant surgeon to the Manchester Royal Infirmary. Five years later he was on the senior staff. He held the post of full surgeon for twenty-four years, until he became consulting surgeon in 1934. He was appointed Professor of Clinical Surgery in 1921 and became Professor Eminentus in 1934.

No other Manchester surgeon has ever had, or is likely to have, as large a private practice as Burgess had throughout his long and strenuous life, but he never let the claims of private patients interfere with his Infirmary or University work. The strain on him must have been immense, but he had a magnificent physique and did not appear to know the meaning of fatigue. To the last he kept his erect military bearing and walked with a quick purposeful gait so characteristic of the man. He will not be remembered as a great philosopher-surgeon, or as the first to describe some new disease, but as the supreme craftsman, the surgeon (or hand-worker) *par excellence*. His greatest triumphs were rather in the operating theatre than in the consulting room or at the lecture desk. He was a good, clear lecturer and never scamped his preparation, but he lacked the tricks of rhetoric. To watch him operate, or still better to assist him, was an aesthetic and intellectual treat. His strong shapely hands possessed rare economy of movement, so that he was a quick operator without ever seeming to be in a hurry. He fought, and won, the local battle for a full aseptic ritual in the operating theatre against the views of senior colleagues who were apt to regard gloves as only needed to protect their hands from pus, and caps and masks as either fads or unnecessary luxuries. He was always keen and enthusiastic and ever on the look-out for some improvement in surgical technique. In this search his many journeys with the Moynihan Chirurgical Club, of which he was an original member and in due course president, were of the greatest value. He hardly ever missed one of its meetings, and from nearly all of them, at home or abroad, he brought back some addition to his surgical technique.

Perhaps Burgess's outstanding characteristic was his intellectual and moral integrity. He was as conspicuously upright in character as he was in carriage. No one ever suggested that he cooked his statistics, nor would he ever descend to a mean or tortuous act. His many acts of kindness and generosity to patients or junior colleagues were done with modesty and almost with diffidence. He was essentially a simple, humble-minded man, and he had an unusually happy life. Magnificent health, the consciousness of work well done that deserved and commanded success, and above all a singularly happy family life combined to secure this. The death of his wife in 1941, to whom he was as utterly devoted as she to him, inevitably left him a rather lonely man despite his lively interest in his children and grandchildren. He sought, and found, solace in work—as he was never idle—and in his gardening and music.

Mr. ARNOLD CADDY died on April 15 at the age of 81 in Melbourne, Australia. He was the son of the late Inspector-General of Hospitals and Fleets, John Turner Caddy, R.N., and was educated at King's College School when it was still in the Strand. He often used to journey to school by "penny steamer" from Battersea Pier. He proceeded to St. George's Hospital, where he qualified in 1887. Mr. Caddy held house appointments at North Lonsdale Infirmary, at Barrow, and at the Leeds General Infirmary. There he came under the influence of Mayo Robson and of Lord Moynihan, who were then beginning their successful careers. After holding these posts he returned to London, took the F.R.C.S. in 1891, and was appointed assistant surgeon to the Cancer Hospital in Fulham Road. Shortly afterwards he was offered a lucrative appointment in Calcutta as a partner of the late William Coulter. He practised there for twenty years and was on the staff of the Marwari Hindu Hospital. He then retired to Australia in 1912. Caddy had married an Australian girl, the daughter of the late Archibald Currie, of Melbourne. He forsook medicine entirely and went in for farming in Victoria. Interested in Red Poll cattle, he founded his own herd and was president of the Red Poll Cattle Association of Australia, winning a championship at the Royal Melbourne Show with his bull Chanpara Valentine. On one occasion he judged at the Chicago International Livestock Exposition. Arnold Caddy was an officer in the Calcutta Light Horse for many years, and during the first world war was in charge of a reinforcement camp of the Victorian Light Horse. He leaves a widow, two sons, and a daughter. The elder son is a gunner colonel in the British Army and is now attached to the rocket bomb installation in South Australia. The second son was in the Australian Forces and was captured at Singapore. He worked on the notorious Bangkok-Moulmein Railway and then in coal mines in Japan before he was released.

Dr. DAVID MURRAY STRATHIE died suddenly at Guy's Hospital on April 18, at the age of 28. He was born in Glasgow and educated at Rugby School, where he was head of his house and captain of the rugby XV. He was a scholar at Trinity College, Oxford, and won his rugby blue in 1939. He entered Guy's Hospital in 1940, and graduated B.M., B.Ch. in 1943. After qualification he held house appointments at Guy's for twelve months before joining the Navy. For a time he was attached to a Naval Rehabilitation Centre on the East Coast of England, and later served in South Africa. He was secretary of the Guy's Hospital Rugby Football Club in 1941-2, and captain during the season 1942-3.

Dr. CYRIL HERBERT THOMAS ILOTT died on April 26 at the age of 68 at Bromley, Kent. He retired only a month ago, and was admitted to hospital only three days before his death. Dr. Ilott was the last medical member of a family of physicians which served the Bromley area for nearly 150 years. Mr. Thomas Ilott, a surgeon, settled in Bromley in 1809. He died in 1849, and was succeeded by his son, who in his turn was followed by the father of Dr. Cyril Ilott. Dr. Ilott was educated at Tonbridge and at Caius College, Cambridge, and St. Bartholomew's Hospital. He qualified in 1906 and graduated M.B., B.Ch. two years later. He was a house-surgeon at the Metropolitan Hospital and a clinical assistant at Great Ormond Street before going into general practice with the firm of Ilott, Scott, and Grant-Wilson. He succeeded his father as Metropolitan police surgeon in 1916, and continued in that capacity until last year. During the 1914-18 war he served in the R.A.M.C. in France and Belgium until he was badly gassed towards the end of the war and had to be invalided home. He had been a member of the board of governors of Bromley and District Hospital since 1928, and in recent years was chairman of the medical staff committee. He was also a member of the Kent Panel Committee.

C. J. M. writes: The death of Dr. Cyril Ilott on the eve of his retirement was a tragedy deplored by a host of friends and colleagues at the Bromley and District Hospital; a short but oppressive illness ended a life of devoted and kindly service to patients and hospital. He had warnings of his danger, but he died in harness in the hospital around which his life had more and more centred. His death breaks the continuity of a family practice of over a century; he had maintained the tradition of intensely personal interest in every patient of whatever section of society—an interest so meticulous and sincere that the modern psychiatrist would have dismissed him as "obsessional." A similar code of honour characterized his relationships with colleagues—practitioners, consultants, nursing and lay staff—at the hospital. By all he was beloved for his sincerity, kindness, and the simplicity of outlook which so often to the superficially minded conceals a very well stored mind and a critical clinical outlook. We all say "Hail and farewell" to a very dear friend and a very good physician.

Medico-Legal

ALLEGED CONSPIRACY TO PROCURE MISCARRIAGES TWO DOCTORS ACQUITTED

The trial took place before Mr. Justice Morris at the Central Criminal Court from May 11 to 14 of Dr. Eleonore Bergmann, of Park Square, N.W., and Dr. Mary Bell Ferguson, of Devonshire Place, W., on an indictment for conspiring together unlawfully to procure miscarriage. A third defendant, Mrs. Pauline Mary Evans, who was Dr. Bergmann's secretary, was found "Not guilty" at an early stage in the proceedings and was dismissed from the case. The proceedings at Marylebone police-court were recorded in our issue of April 17 (p. 762).

Mr. Anthony Hawke, who prosecuted, said that the alleged offences with which Dr. Bergmann was charged related to the use of an instrument to procure the miscarriage of four women between Dec. 16 and Jan. 24 last. Dr. Ferguson was associated with only two of these cases. These two women first consulted Dr. Bergmann, who sent them to Dr. Ferguson, and the latter, after examination, forwarded to Dr. Bergmann a letter expressing the opinion that the operation could be lawfully performed for the reasons she indicated. The question so far as Dr. Ferguson was concerned was whether her opinion was given in good faith or was simply, as Mr. Hawke alleged, to provide a cover for Dr. Bergmann in case of emergency.

The principal evidence for the Crown was that of the four women concerned, whose names were not divulged. Their evidence was summarized in our earlier report. It was stated that the fees received by Dr. Bergmann were in the first case (a nurse) £10, in the second and third cases £75, and in the fourth case £50.

Both defendants pleaded "Not guilty." Dr. Bergmann, in reply to Mr. G. D. Roberts, K.C., her counsel, said that she was born in Germany in 1907. She qualified in 1933 and set up as a general practitioner in Edgware; afterwards she had consulting rooms in Park Square. She had never met Dr. Ferguson before they both stood in the dock at Marylebone police-court, but she had heard about her, her work at Tavistock Clinic, and her high standing in psychological medicine. She had sent a number of patients to Dr. Ferguson for her opinion. Of those which turned on the desirability of terminating pregnancy she could recall six in which Dr. Ferguson had not recommended this course, and the operation accordingly had not been performed. Of the two out of the four cases in which Dr. Ferguson was not concerned, the first was a woman who had made a partially successful attempt at procuring abortion, and on examination Dr. Bergmann was convinced that there was no foetal life. The other was a woman who had had a baby a few months previously and was afraid she was pregnant again, but on examination Dr. Bergmann found that not to be the case, and the curetting which was done was in order to clear up a uterine condition and not to terminate pregnancy. Of the other two cases, one was a haemophilic and in a shocking condition, and the other in an exhausted and anxious state, complicated by a recent attack of jaundice.

Dr. Ferguson gave evidence that she had been a member of the medical profession since 1910, and for the last twenty years had specialized in the study of mental disorders. A certain number of the cases in which she was consulted were women whose condition was complicated by pregnancy. In January two cases were sent to her by Dr. Bergmann, whom she had never met socially or professionally, and she came to the conclusion in each of these that in the interests of the women the pregnancy should be terminated. This conclusion she wrote in a letter to Dr. Bergmann. Her fee in each of these cases was the regular consultation fee of three guineas, and that was all she received in connexion with this matter.

In cross-examination Mr. Hawke took Dr. Ferguson through the various disabilities which she had set down in her letter on one of the cases and asked whether each of them—exhaustion, digestive trouble, etc.—constituted a reason for performing the operation. Dr. Ferguson replied that her opinion was based on all the various matters added up together—on the general state, not on a particular item. She admitted that she had

first suggested to one of the girls that she should have her baby and get it adopted, but that was before she went fully into her history and condition. This was a psychoneurotic girl who in addition had chest trouble, and she recommended the termination of pregnancy on both physical and mental grounds. One was always reluctant to terminate a pregnancy if this course could be avoided. She gave both certificates in complete good faith.

Mr. Roberts, for Dr. Bergmann, said that while it was vitally important that the unborn should not be unlawfully destroyed it was equally important that women whose pregnancy, if it was allowed to continue, might disastrously affect their health and endanger their life should be free and able to have their pregnancy terminated under safe conditions. It would be utterly wrong if the result of this case was to deter doctors from doing their duty. He submitted that Dr. Bergmann had full justification in each case for what she did and that she was entitled to leave the court as a member of a free and honourable profession which in all her professional life she had done everything to uphold.

Mr. E. Davies, K.C., for Dr. Ferguson, said that collusion was the essence of the charge against her. What indications were there of any sort of collusion? It was brought out in evidence that it was only after two of the women had told Dr. Bergmann that they had no doctor that she had mentioned Dr. Ferguson's name. There was no suggestion that Dr. Bergmann or Dr. Ferguson shared fees, or that Dr. Ferguson knew that the operation had been performed or where it was performed. She was a woman of unblemished reputation. Was a woman going to sacrifice nearly forty years of honourable service in her profession for six guineas?

Mr. Hawke, in a closing speech, submitted that there was evidence that Dr. Ferguson's certificates were a cloak ready to be produced at the proper time to cover an operation which to the knowledge of the person performing it was unlawful. He pointed out that Dr. Bergmann's story in the witness box, especially with regard to the case which she now said was not pregnant at all, differed from the story she had told the police inspector. The case against Dr. Bergmann was formidable, and Dr. Ferguson must be regarded as accessory to the fact of these operations.

Summing-up

Mr. Justice Morris, in summing up, pointed out that the four women who had given evidence for the prosecution were themselves parties to an alleged unlawful act, and therefore it was highly desirable that there should be corroboration. In the case of one of the women—the woman whom the defence said was not pregnant at all—there was no corroboration of her story that she was. The jury was not concerned in this case, as in so many others at that court, with unqualified people performing this operation, and it must happen from time to time that those engaged in the practice of medicine had to perform, lawfully, operations for the termination of pregnancy. Here his lordship read from the summing-up in the case of *Rex v. Bourne* (1938); although the facts in one case were not of overwhelming assistance in another, they did afford a certain guidance on principle, and it might be helpful to read a few words from the summing-up of the judge in that case (Mr. Justice Macnaghten). After pointing out that the burden rested upon the Crown to satisfy the jury beyond reasonable doubt that the defendant's procurement of miscarriage in the girl was not done in good faith for the purpose of preserving her life, the judge had continued:

"The law does not permit the termination of pregnancy except for the purpose of preserving the life of the mother. I think myself that those words ought to be construed in a reasonable sense. If the doctor is of opinion, on reasonable grounds, and with adequate knowledge, that the probable consequence of the continuance of pregnancy would indeed make the woman a physical or mental wreck, juries are quite entitled to take the view that the doctor who in those circumstances and in that honest belief operates is operating for the purpose of preserving the life of the mother."

"I fully adopt those words," said Mr. Justice Morris, "and invite you to bear them very much in mind."

His Lordship, referring to the certificates given by Dr. Ferguson, said that it was no part of the jury's duty to decide whether she had arrived at a right conclusion on the two cases. A

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH

At a quarterly meeting of the College held on May 4, with the President, Dr. W. D. D. Small, in the chair, Drs. H. A. Raeburn (North Berwick), G. M. Wilson (Edinburgh), and D. N. Dobbie (Bromley, Kent) were introduced and took their seats as Fellows of the College. Drs. E. H. Duff (Selkirk) and E. K. Morris (Edinburgh) were elected Fellows of the College.

Drs. R. C. L. Batchelor (Edinburgh), C. W. Clayson (Lochmaben, Dumfries), J. F. Galpin (Coventry), R. J. McGill (New Milton, Hants), J. E. A. David (Bulawayo, S. Rhodesia), Yu Hans Tang (Hong Kong), V. Solomon (Johannesburg), G. W. Senter (Edinburgh), W. S. Thomson, Jr. (Leicester), M. R. Clarke (Capetown), C. G. Williams (Durban), K. J. Dunlop (Edinburgh), T. B. Binns (Middlesbrough), A. V. Bird (Johannesburg), R. J. G. Sinclair (Edinburgh), J. O. Forfar (Dundee), M. Medalie (Johannesburg), D. K. Stevenson (York), J. R. Fountain (West Hartlepool), I. D. B. Bottomley (Wallasey), D. Hilson (London), K. Greenwood (R.A.M.C.), B. B. Manna (Bengal), F. L. Ritchie (Sydney), H. Shrand (Capetown), and Beatrice M. Wilson (Edinburgh) were elected Members of the College.

The Lister Fellowship (value £100), for original research carried out in the laboratory of the College, was awarded to Dr. T. W. Lees (Edinburgh).

Dr. Douglas Kerr was re-elected Representative of the College on the General Medical Council for a period of five years.

SOCIETY OF APOTHECARIES OF LONDON

The fifth Joseph Strickland Goodall Memorial Lecture on Cardiology will be delivered by Prof. John McMichael, M.D., F.R.C.P.Ed., Director of the Department of Medicine, Postgraduate Medical School of London, at the Apothecaries' Hall, Black Friars Lane, Queen Victoria Street, London, E.C., on Thursday, June 3, at 5 p.m. His subject is: "The Pharmacology of Heart Failure." Members of the medical profession and senior students are invited to attend.

Medical Notes in Parliament

The Report of the Inter-Departmental Committee on the remuneration of general dental practitioners was presented to Parliament on May 11.

The Factories Bill and the Veterinary Surgeons Bill, both of which have passed the House of Lords, were read a first time in the House of Commons on May 11.

Mental Deficiency Regulations dated May 10, 1948, were laid on the Table of the House on May 12.

The National Insurance (Industrial Injuries) Bill was read a second time in the House of Commons on May 12.

National Insurance Contributions

Mr. ERROLL asked on May 13 how much of the weekly insurance contribution payable by the individual on and after July 5 would be a contribution to the Health Service.

Mr. STELLI answered that Section 37 of the National Insurance Act provided for lump sum payments to be made out of the National Insurance Fund to the Exchequer as a contribution towards the cost of the National Health Service. These lump sum payments were financed by allocating 8½d. out of each weekly National Insurance contribution paid by an employed man and 6½d. by an employed woman. In addition, 1½d. of the employer's contribution was allocated to the National Health Service. In the case of self-employed and non-employed persons the corresponding allocations were 10d. for a man and 8d. for a woman.

Special Procedure

On May 13 Sir ERNEST GRAHAM-LITTLE asked the Minister of Health which existing committee fulfilled the request by the Royal College of Physicians, which he promised to consider, for a special procedure by way of a committee to provide a check on the issue of Regulations such as would determine the qualifications, remuneration, and conditions of service of doctors and dentists under the National Health Service Act, 1946.

Mr. BEVAN replied that the present procedure, under which all Regulations had to be examined by a special committee in Parliament, coupled with his undertaking to remove from the scope of Regulations a full-time salaried general practitioner, should be sufficient to remove any apprehension on

Choose Your Doctor Now

Sir JOHN MELLOR asserted on May 12 that the phrase "Choose your doctor now" in a pamphlet to which he had drawn attention was meaningless at the present time. He asked whether Mr. Bevan knew that the London Executive Council asked inquirers to call again in a month, by which time it hoped that the difficulties would be removed.

Mr. BEVAN promised to inquire at once to find whether the London Executive Council was giving that advice. He was fairly certain that the allegation was untrue and that Sir John Mellor was misinformed. He thought all members of the House were now anxious to facilitate the starting of the Act on July 5.

Mr. ASSHETON asked if Mr. Bevan knew that whereas some propaganda put forward by his Department advised the public that lists of doctors could be found in post offices, these lists could not be found there.

Mr. BEVAN said the lists would appear in post offices and town halls as they were filled up by doctors applying to join the Service. There was obviously some delay among certain doctors at present, but they were participating in larger and larger numbers. It was to the financial interest of the doctors to get these lists filled as early as possible. As soon as the doctors had indicated their intention of participating in the Service their names would be put in the places indicated by the leaflet. He added, "We must have the support of the public and medical profession unless great inconvenience is to be caused to millions of people."

Mr. DRIBERG said public-spirited doctors in places such as Maldon had made public their intention of coming in, and the only difficulty was that the supply of application forms ran out at post offices because of the enthusiasm of the public.

Mr. BEVAN promised to see that the supplies of leaflets marched with the mounting enthusiasm. Answering Squadron-Leader FLEMING, he said the House had been speaking about general practitioners and not of specialists and consultants, who were attached to Regional Boards and teaching hospitals.

Children's Bill

The Children's Bill, which had passed the House of Lords, was read a second time in the House of Commons on May 7. During the discussion Dr. HADEN GUEST said the feeling in the minds of medical officers was that in no circumstances must the power be taken from local authorities to go into premises to see the children and to inspect the premises.

The Nurseries and Child-Minders Regulation Bill was read a first time in the House of Commons on May 6.

Mr. STRACHEY said on May 10 that steps recently taken by the Ministry of Food should ensure that reasonable supplies of the various brands of infants' foods were available in all districts. National dried milk was readily available in all areas.

A resolution approving the Purchase Tax No. 1 Order, 1948, on drugs and medicines was moved by Sir STAFFORD CRIPPS on May 6 and was carried without debate.

Exchange Control Medical Advisory Committee

Commander NOBLE on May 11 asked how many people suffering from tuberculosis and recommended treatment in Switzerland had been refused the necessary exchange during the past twelve months.

Mr. GLENVIL HALL said that of 1,317 cases considered by the Exchange Control Medical Advisory Committee since its formation in December last, 22 involving tuberculosis of all types were not considered suitable cases for which currency should properly be provided.

Shortage of Beds.—Mr. BEVAN stated on May 13 that hospital authorities returns at Dec. 31, 1947, gave the number of vacant beds for which staff was not available as 61,146. This was about 2,000 less than the corresponding figure at Sept. 30, 1947. He added that his Ministry was doing what it could to remedy the shortage of nurses.

Opticians Register.—Mr. MITCHELSON asked on May 13 whether Mr. Bevan had considered representations from the Joint Emergency Committee of the optical profession asking that provision should be made by legislation for the registration of opticians. Mr. BEVAN said that Mr. Woodburn and he proposed to set up an Inter-departmental Committee to consider and advise whether such legislation would be to the public advantage and if so how registration could best be carried out and what qualifications should be required as a condition of registration. They would consult the professions concerned as to the constitution of the Committee.

Mental Defectives.—The number of mental defectives in public institutions on Jan. 1 was 53,207. The number awaiting removal to institutions on that date was 3,905.

Medical News

Prof. G. Grey Turner

G. Grey Turner, M.S., F.R.C.S., Emeritus Professor of Surgery in the University of London, has been elected a Foreign Corresponding Member of the French Académie Nationale de Médecine.

Accommodation at Annual Meeting

The accommodation at Cambridge for the Annual Meeting of the B.M.A. is limited. In order that the arrangements may run smoothly we would ask those who intend being present to notify the Executive Officer as soon as possible. The form for doing so appeared in the *Supplements* of April 24, May 8, and May 15.

Awards for Penicillin Research

Sir Alexander Fleming, F.R.S., and Sir Howard Florey, F.R.S., were presented with the United States Medal for Merit on May 18 by Mr. Lewis Douglas, the United States ambassador. The award is for their research on penicillin.

Physical Education Appointment

Dr. Ernst Jokl has been appointed Physical Education Research Officer to the Union Education Department by the South African Government.

Danish Surgeon's Visit

Dr. Jens Foged, Chief Surgeon at the Bispebjerg Hospital in Copenhagen, is spending a month in Britain under the auspices of the British Council to meet plastic and gastric surgeons.

Golf Competition

The Manchester and District Medical Golfers Association will be holding its Annual Competition on May 26 at Merc, Cheshire. Particulars about membership of the club may be obtained from the Honorary Secretaries, Manchester and District Medical Golfers Association, c/o British Medical Bureau, 33, Cross Street, Manchester, 2.

Third International Blood Transfusion Congress

Dr. H. F. Brewer has been appointed to represent the British Red Cross Society's London Blood Transfusion Service at the Third International Blood Transfusion Congress which is being held at Turin from May 30 to June 2 inclusive.

Control of Poisons

The following substances are added to Part I of the Poisons List and to the First Schedule to the Poisons Rules: Amidone and its salts, carbachol, alkaloids of curare and curare bases (in substitution for "curarine," which is now deleted from the List and the Schedule), metopon and its salts, sodium monofluoroacetate. Allylisopropylacetylurea is deleted from the Seventh Schedule and added to the Fourth Schedule to the Poisons Rules. It thus becomes subject to the same conditions with respect to supply and labelling as the barbiturates and sulphonamides. The requirement about colouring is widened to include arsenical poisons intended for the treatment of any infestation: lead arsenate paste and powder must now be coloured, and the colouring must be of such a nature as to be apparent whether the poison is dry, or wet, or in solution.

Spens Report on Dentists

The Report of the Interdepartmental Committee (Chairman, Sir Will Spens) on the Remuneration of General Dental Practitioners has been published as a White Paper (H.M.S.O., 4d.). The Committee was appointed on Sept. 2, 1946, to consider "what ought to be the range of total professional income of a registered dental practitioner," with regard to the normal financial expectations of dental practice in the past and the desirability of maintaining the status of the profession. Net incomes—that is, gross remuneration less professional expenses allowed for income tax—were examined in terms of the 1939 value of money. The Committee found that very few dentists make large incomes, that most earn less than enough to meet minimum middle-class expenditure, and that a quarter of the profession live below this standard. Witnesses impressed the Committee with the exceptional arduousness of dental work and it concludes that to work more than about 33 hours by the chair-side for 46 weeks a year tends to impair efficiency. Recruitment is poor and the profession must be made more attractive. The Committee recommends that dentists earning below £400 should be doubled, those of £400-£800 should be augmented by £400, and those above £800 should be augmented by one-third of the amount by which they fall short of £1,200. An experienced dentist working single handed and fully

employed for the hours suggested should earn £1,600 net. However if there were sufficient dental practitioners in relation to demand to secure a spread of incomes comparable to that of 1938, 75% aged between 35 and 54 should receive over £850 a year, 50% over £1,100 a year, and 25% over £1,400. Practitioners with junior partners or salaried assistants could properly earn more, as could the younger and more energetic dentists working more than 33 hours a week. Special provision should be made for dentists serving sparsely populated areas. Dental specialists with higher qualifications ought to be remunerated within the same range as medical specialists.

Chelsea Clinical Society

The annual dinner of the 51st session of the Chelsea Clinical Society was held at the South Kensington Hotel on May 11. The toast of the Society was proposed by Sir Walter Monckton, K.C. Speaking as a representative of a "much misunderstood" profession, Sir Walter touched wittily upon the relations between Medicine and Law. In his reply the President, Dr. Neil Maclay, gave the briefest possible account of a successful year in which the Society had achieved a balanced budget. Mr. Ivor Back proposed the toast of the guests, and Sir Leonard Stone, K.C., replied. At the close of the evening Dr. Maclay handed over the badge of office to the new President, Mr. Nils Eckhoff.

Wills

Dr. Arthur Charles Douglas Firth, formerly consulting physician to King's College Hospital, left £21,243; Dr. George Harold Lowe, of Middlesbrough, £15,570; Dr. Alexander Moxon Webber, of Sandown, Isle of Wight, £13,067; Dr. Edward Raymond William Gilmore, formerly M.O.H. for Leamington Spa, £4,645; and Lieut.-Col. John Lumsden Lunham, late I.M.S., £92,143.

COMING EVENTS

Hygiene in Food and Drink Industry

A joint meeting of the Food Group of the Society of Chemical Industry and the Royal Sanitary Institute will be held at Royal Hall, Ripon Road, Harrogate, on Friday, May 28, at 10 a.m., when the general subject for discussion will be "The Cleaning and Sterilizing of Plant in the Food and Drink Industry." The meeting will constitute the Food and Nutrition Section of the Health Congress of the Royal Sanitary Institute, which will be held at Harrogate from May 24 to 28.

Training of Social Therapists

A full-time three months' course for the training of social therapists will begin on June 1 and a year's evening course on Oct. 18. The fees for the courses, which are being given under the auspices of the Institute of Social Psychiatry, are £26 5s. and £52 10s., respectively. Inquiries should be addressed to the Social Psychotherapy Centre, 7, Fellows Road, London, N.W.3.

Westminster Hospital (All Saints') Urological Centre

Dame Katherine Watt, D.B.E., R.R.C., Chief Nursing Officer of the Ministry of Health, will open a new nurses' home at the Westminster Hospital (All Saints') Urological Centre, Austral Street, West Square, London, S.E., on Thursday, June 3, at 2.15 for 2.30 p.m.

SOCIETIES AND LECTURES

Monday

EDINBURGH UNIVERSITY: PHYSIOLOGY CLASSROOM.—May 24, 5 p.m. "The Great Epidemics of History," by Dr. Douglas Guthrie.
UNIVERSITY COLLEGE LONDON.—At Anatomy Theatre, Gower Street, W.C., May 24, 5.30 p.m. Shearman Lecture: "The Origin and Nature of Scientific Thought," by Mr. E. Schrödinger, Ph.D., D.Sc.

Tuesday

EDINBURGH POSTGRADUATE BOARD FOR MEDICINE.—At Edinburgh Royal Infirmary, May 25, 5 p.m. "Clinical Physiology of the Pulmonary Circulation," by Prof. W. Melville Arnott.
EUGENICS SOCIETY.—At Burlington House, Piccadilly, London, W. May 25, 5.30 p.m. "Migration and the British Commonwealth," by Prof. Brinley Thomas, M.A., Ph.D.
INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—May 25, 5 p.m. "Bullous Eruptions," by Dr. R. T. Brain.

Wednesday

GLASGOW UNIVERSITY: DEPARTMENT OF OPHTHALMOLOGY.—May 26, 8 p.m. "Cataract Extraction," by Mr. O. M. Duthie.
UNIVERSITY COLLEGE LONDON.—At Physiology Theatre, St. Mary's Hospital Medical School, Paddington, W., May 26, 5 p.m. Special Lecture: "The Localization and the Role of Nucleic Acids in the Cell," by Prof. J. Brachet (Brussels). At Anatomy Theatre, University College, Gower Street, W.C., 5.30 p.m. Shearman Lecture: "The Origin and Nature of Scientific Thought," by Mr. E. Schrödinger, Ph.D., D.Sc.

Any Questions.

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Pleural Effusion

Q.—What is the correct method of investigation of a pleural effusion? When the diagnosis is in doubt, is guinea-pig inoculation of value? I have difficulty in distinguishing between effusions of tuberculous, pneumonic, neoplastic, and transudate origin. The problem is particularly difficult in the following two circumstances: (a) in patients who have been treated—e.g. by chemotherapy—for some little time before admission to hospital; and (b) where the effusion is so large that it obscures all, or the greater part of, the underlying lung tissue. I have always regarded guinea-pig inoculation as a pointer to diagnosis, but some of my colleagues maintain that it is of little value.

A.—In the investigation of a pleural effusion the history and clinical findings are of the greatest importance. The chief varieties which must be distinguished are the "idiopathic"—the majority of which are tuberculous—the pyogenic, and the malignant. In the malignant group the history, age of the patient, and blood-staining of the effusion are important diagnostic points. A tuberculous effusion is relatively uncommon in a patient of carcinoma age. The frankly pyogenic effusion—e.g. complicating pneumonia or lung abscess—rapidly becomes an acute empyema, but after chemotherapy a sterile effusion may result. It may be very difficult to differentiate between this and a tuberculous effusion, but the predominant cells are usually polymorphs and the history of contact may aid infection may be a guide. In a tuberculous effusion the age of the patient, mode of onset, and history of contact may aid the diagnosis. Loewenstein culture or, better still, guinea-pig inoculation of the fluid should be performed in all cases, and some authorities claim a positive result from inoculation in three out of four tuberculous effusions. This is an optimistic estimate. A negative result does not exclude tuberculous.

Alternative to Venesection

Q.—While in America during the war I was told of a clinical procedure carried out in acute left-sided heart failure. The rationale of venesection in acute pulmonary oedema or in a hypertensive "cardiac asthma" attack is to relieve the load on the left ventricle and also perhaps on the right. In the U.S.A. it seems to be a common alternative to venesection to apply two sphygmomanometer bands to alternate limbs for, say, 20 minutes, and then to repeat on the other two limbs. The bands are applied at a pressure midway between the diastolic and systolic. This acts at once in stopping large quantities of venous blood returning to the heart, and is apparently effective in treating these conditions. Has this treatment been tried in this country?

A.—The method of reducing the return of blood to the heart described in the question has been used in this country for a number of years. The effect is immediate, the pressure in the right auricle being reduced and the cardiac output increased. On releasing the cuffs the blood return is reduced for some time by the vasodilatation induced in the treated limbs. Its danger lies in the possible production of thrombophlebitis by obliteration of superficial veins or in the formation of thrombi in deep muscle capillaries which may spread and result in pulmonary infarction.

Removal of Tattoo Marks from the body by

Q.—Is it possible to remove tattoo marks from the body by plastic surgery or by any other method?

A.—Tattoo marks are foreign bodies in the skin and can only be removed surgically. The removal of tattoo marks from most of the favourite sites on the body is possible by excision and plastic repair. In the case of small designs the defect is often closed by sliding flaps and direct suture.

Thursday
BRITISH INSTITUTE OF RADIOLOGY.—At Reid-Knox Hall, 32, Welbeck Street, London, W., May 27, 6 p.m. "The Roentgen-Anatomical Appearance of Infantile Pyloric Stenosis, Before, During, and After the Manifest Stage of the Disease," by Dr. Gösta Runstrom (Gothenburg).
EDINBURGH ROYAL INFIRMARY.—May 27, 4.30 p.m. Honyman Lecture: "Partial Gastrectomy for Peptic Ulcer," by Mr. H. W. Porter.
MEDICO-LEGAL SOCIETY.—At 26, Portland Place, London, W., May 27, 8.15 p.m. "The Investigation of Crime," by Cyril R. M. Cuthbert, Chief Detective Inspector, Metropolitan Police Laboratory.

UNIVERSITY COLLEGE LONDON: DEPARTMENT OF PHARMACOLOGY.—At Physiology Theatre, Gower Street, London, W.C., May 27, 5.15 p.m. "Biological Responses to Drugs," by Mr. J. F. Danielli, Ph.D., D.Sc.

Friday
KENT AND CANTERBURY HOSPITAL. Canterbury.—May 28, 5 p.m. Monthly Clinical Meeting.
UNIVERSITY COLLEGE LONDON.—At Physiology Theatre, St Mary's Hospital Medical School, Paddington, W., May 28, 5 p.m. Special Lecture: "The Localization and the Role of Nucleic Acids in the Embryo," by Prof. J. Brachter, W.C., 5.30 p.m. Theatre: "The Origin and Nature of Scientific Thought," by Mr. E. Schrödinger, Ph.D., D.Sc.

Saturday
BIOCHEMICAL SOCIETY.—At Department of Biochemistry, University Museum, Oxford, May 29, 1 p.m. 267th meeting of the Society. Papers will be read

APPOINTMENTS

Duncan Yuille, M.B., Ch.B., has been appointed to succeed Dr. Gebbie as Divisional Surgeon of the Hull Northern Division of the St. John Ambulance Brigade

HOSPITAL FOR SICK CHILDREN. Great Ormond Street, London, W.C.—First Assistant Anaesthetist, T. D. L. Roberts, M.R.C.S., L.R.C.P., D.A. Resident Medical Registrar and Pathologist, D. A. Williams, M.D., M.R.C.P., D.C.H. House-physician, I. D. H. Matthews, M.B., Ch.B., M.R.C.P., D.C.H. Surgeon, J. P. Rochford, B.M., B.Ch.

LONDON COUNTY COUNCIL.—The following appointments in the Council's Mental Health Services are announced at the hospitals indicated in parentheses: Assistant Medical Officers: J. Donnelly, M.B., Ch.B. (Cane Hill), M. Engler, M.D., D.P.M. and E. J. Rich, M.B., B.S. (The Manor), R. Krambach, M.R.C.O.G. (Bantleed); H. H. Robinson, M.B., B.Ch. (St. Ebbas), T. St. J. H. Silvester, M.R.C.S., L.R.C.P. (Beckley).

LUDLAM, G. B., M.B., Ch.B., D.I.C., D.T.M. & H., D.S. Director, City Bacteriological Laboratory, Nottingham.

MICHELL, ROBERT, M.D., Ch.B., D.P.H. Assistant Medical Officer of Health, County Borough of Bury

PETERS, P. M., B.M., B.Ch. Assistant Pathologist, Department of Morbid Anatomy, Prince of Wales's General Hospital, London, N.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Fisk.—On May 5, 1948, at Stella Mans Nursing Home, Cambridge, to Dr Susan Airey, wife of Geoffrey Fisk, M.B., F.R.C.S. Ed., Winc Commander, a daughter—Susan Clare.

Howat.—On May 11, 1948, at Newcastle, to Margaret Barker, wife of James Howat, a son.

DEATHS

Altherton.—On May 9, 1948, at Cotswold Sanatorium, Charles Umpherson Altherton, M.R.C.S., L.R.C.P., aged 38.

Arnold.—On May 10, 1948, Edwin Gilbert Emerson Arnold M.D., M.R.C.P., Hugh Arthur, M.D., aged 73.

Caddy.—On May 12, 1948, at Neys End, Brockham Bitchworth, Surrey Joseph Caddy, on April 15, 1948, in Melbourne, Arnold Caddy, F.R.C.S., of Chandpara, Tilden, Victoria, Australia, aged 81.

Dickinson.—On May 8, 1948, at Royal Hospital, Sheffield, William Robinson Dickinson, M.R.C.S., L.R.C.P., of Loxley, Hough Lane, Wombwell, Yorks, aged 52.

Gray.—On May 4, 1948, at Girvan, Alexander Gray, M.B., Ch.B. Glas., of 46, Main Street, St. Ninians, Stirling.

Kilbally.—On May 9, 1948, at Cooldaniel, Greystones, Co. Wicklow, Elre, Patrick Percy Kilbally, M.B., B.Ch., Lieutenant-Colonel, I.M.S., retired.

Lachy.—On May 11, 1948, at The Newk, Lanark, John Macintyre, M.B., Ch.B. Glas., D.P.H.

Richardson.—On May 11, 1948, at Bucklands, Dover, Joseph Richard Whitehead Richardson, M.R.C.S., L.R.C.P., aged 48.

Stone.—On April 10, 1948, at 6, Cheyne Walk, Northampton, David Stone, M.D., C.M.Glas., aged 82.

Thom.—On May 8, 1948, at Castlepark, Larark, Ernest Graham Young Thom, M.B., Ch.B.

Vines.—On May 8, 1948, at Broadwell, Newport, Mon., Charles Stuart Vines, M.R.C.S., L.R.C.P., D.P.H., aged 82.

In most cases, however, the raw area is best filled with a split skin graft. On a fresh base this should "take" excellently. The only other useful method is to modify or black out the design by further tattooing. Splitting the skin in the hope of removing the marks is rarely successful, as the particles lie too deeply imbedded in the dermis.

Proetz Displacement Method

Q.—Though the Proetz displacement method using a solution of ephedrine is mentioned in textbooks as having a place in the treatment of maxillary sinusitis, I am unable to find out the practical details involved—e.g., the quantity of solution used, the position of the patient's head, and the method of evacuating air from the sinus so as to ensure its replacement by the solution. Could you supply this information?

A.—The Proetz syringe has 5- and 10-ml. graduation marks on the glass barrel. The patient lies flat on the back, with a small pillow under the shoulders, so that the head is almost upside down. Breathing quietly through the mouth, the patient introduces 5 ml. of the solution, usually 0.5 or 0.75% ephedrine in normal saline, into one nostril. The syringe is then removed, the bulb squeezed, and the nozzle reinserted. The other nostril is occluded and the bulb allowed to expand. If no suction is experienced the process is repeated while the patient says, "Kick, kick, kick." After repeating this suction once or twice sufficient solution should have entered the sinuses, and the other side can then, if necessary, be treated in exactly the same way. It will be found easier to try the method first with the syringe empty.

Stilboestrol and New Growth

Q.—Has stilboestrol ever been responsible for the disappearance of a new growth? A woman, aged 60, had a hard growth, which was beginning to ulcerate and was firmly attached to the sternum. Seemingly it was a sarcoma of the sternum, but more likely was a carcinoma arising in the left breast. The condition had been present for 18 months, but when first seen five months ago she had a left pleural effusion, was breathless in bed, and apparently moribund. Her only treatment has been stilboestrol 5 mg. thrice daily, and on this she has made a remarkable recovery; she is now doing light housework. The growth itself has almost disappeared. What is the expectancy of life in this case, and how long should the stilboestrol be continued?

A.—So far as is known, stilboestrol has never effected the complete regression and permanent disappearance of a new growth. When treated with oestrogens, some 5% of post-menopausal cases of cancer of the breast (such as the above is presumed to be) may improve in a similar way to that described. Improvement is temporary, however, and although its duration is usually no more than several months, cases have been observed in which the disease appeared to be quiescent for considerably longer periods. Nevertheless, in the majority of such cases the expectation of life is not likely to be demonstrably greater than without treatment. Since exceptionally favourable responses undoubtedly occur, even although unpredictably, stilboestrol therapy should be continued.

Diarrhoea due to *Salmonella typhi* murium

Q.—A patient has had attacks of diarrhoea for twelve months which recently were proved to be due to *S. typhi* murium. Can you suggest ways of permanently destroying the organism in his bowel?

A.—*S. typhi* murium is a common cause of acute gastro-enteritis and is one of the organisms most often responsible for outbreaks of food-poisoning. Occasionally it may give rise to a more prolonged fever accompanied by gastro-intestinal symptoms, but it would be most unusual for it to lead to recurrent attacks of diarrhoea over a period of a year. A number of these infected remain carriers, and it is possible that the organism in the present case is merely saprophytic. Nevertheless it is clearly important to try to eliminate it from the patient's stools, as its persistence is a danger to the community. The only agents likely to be effective are sulphamidine, sulphasuxidine, or phthalyl sulphathiazole. Suitable doses for such a purpose in an adult would be 2 g., 1.5 g., and 1.5 g., respectively, six times daily for about ten days.

Surgical Treatment of Peptic Ulcer

Q.—It has been shown that a peptic ulcer which is bathed in alkaline secretion always heals. Why, then, in the operation of partial gastrectomy for duodenal ulcer is it considered necessary to dissect out and remove the ulcer instead of being satisfied with a prepyloric division of the stomach with dissection and removal of the pyloric mucous membrane? The dissection of the duodenum is almost always the most difficult and even dangerous part of the operation.

A.—Theoretically, Bancroft's operation, or a prepyloric resection combined with removal of the antral mucosa, is a perfectly satisfactory answer to the surgical treatment of duodenal ulcer. In fact the operation is not so simple as it sounds, because (1) haemorrhage from the cut mucosa inside the musculo-serous sac of the antrum is often profuse and difficult to deal with, and (2) the closure of the thickened wall of the antrum is seldom as efficient as that of a duodenal stump. In the case of a difficult adherent duodenal ulcer the better procedure is probably the two-stage gastrectomy—a primary prepyloric resection followed a month to six weeks later by the removal of the pylorus and first part of the duodenum with the ulcer. This second stage is often surprisingly easy.

Acne Rosacea

Q.—A farmer, aged 55, suffers from rosacea and is developing a vascularizing keratitis in both eyes. Is there any evidence to show that daily intravenous injections of nicotinic acid 50–100 mg., together with bi-weekly intramuscular injections of riboflavin 10 mg., would benefit the condition? In view of the intense flushing of the face that would occur after the nicotinic acid injection, is this treatment contraindicated?

A.—Results are claimed for the use of riboflavin in acne rosacea. The evidence for nicotinic acid is more scanty. Treatment is on the whole disappointing. While there is some justification for the use of riboflavin, attention must be concentrated on standard and orthodox measures such as atropin drops where the corneal condition calls for it. It would appear that the best results are perhaps obtained from x-ray treatment in doses of 50 r.

NOTES AND COMMENTS

Antrochoanal Polypi.—Dr. GAVIN YOUNG (Glasgow) writes: With reference to the answer on this subject ("Any Questions?" May 1 p. 866), it might have been added that by far the most common cause of anosmia is the "waterlogging" of the mucosa of the olfactory cleft associated with nasal allergy. The antral cavity mentioned in the question may well have been the subject of allergy with superadded infection. It is the writer's firm conviction that the incidence of nasal allergy is very greatly on the increase possibly the result of food deficiencies.

Congenital Deafness and German Measles.—Dr. K. HAZELL, of the Metropolitan Ear, Nose and Throat Hospital, London, writes: I am anxious to receive information from doctors on this subject. (1) Concerning patients congenitally deaf: whether the mother (i) had a rash during pregnancy; (ii) did it resemble German measles? (iii) at what time after conception? (iv) in which year? (v) did she, previous to pregnancy, have German measles? (2) Concerning German measles (or a disease resembling it) during pregnancy: was the child subsequently normal or abnormal, and, if the latter, how affected?

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY MAY 22 1948

British Medical Association PROCEEDINGS OF COUNCIL

Wednesday, May 12, 1948

A meeting of the Council of the Association was held at B.M.A. House, London, on May 12, with Dr. H. Guy Dain in the chair.

Preliminary

The Chairman referred with deep regret to the sudden death of Prof. A. H. Burgess, President of the Association in 1929-30 and afterwards for many years a member of Council and Vice-President. He said that after his year of presidency Prof. Burgess continued to take an active part in the work of the Association, and was not only a valued member of its Council and committees but a very great friend to many of them.

Dr. S. Wand said that long before Prof. Burgess became President he worked actively in the interests of the Association. It was through his influence with the graduates of Manchester University that so many of them joined the Association immediately upon qualifying.

Mr. A. M. A. Moore, on behalf of the Consultants and Specialists Committee, joined in the tribute Prof. Burgess was for many years chairman of the Special Practice Committee, and it was in no small measure due to him that the new organization of consultants and specialists was so well established.

The members of Council stood for a few moments in silence.

Dr. J. A. Pridham gave a brief report of his attendance in New York at the council meeting of the World Medical Association and handed over a banner bearing a Chinese greeting which he had been asked by the representatives of the Chinese Medical Association to present to the Council on his return. The meeting in New York, at which twelve different countries were represented, had proved highly successful and most harmonious. Real progress was made in consolidating the Association. It was obvious that the W.M.A. had a great future before it. Dr. Pridham also mentioned the extraordinary kindness and courtesy with which he, as British representative, had been received in America, where the members of the medical profession were watching with deep interest the progress of medico-political events in Great Britain.

The Chairman expressed to Dr. Pridham the thanks of the Council for undertaking the long journey and representing the Association at this meeting.

It was reported that an invitation had been received from the Medical Association of South Africa to hold an Annual Meeting in Johannesburg. It will be recalled that before the war provisional arrangements had been made for the Annual Meeting to be held in the Union of South Africa in 1940 or 1941. The Federal Council had now renewed the invitation, the suggested place of meeting being Johannesburg and the time provisionally recommended 1950 or 1951.

The President (Sir Hugh Lett), who had recently visited South Africa, said that the profession out there was looking forward very eagerly to this visit from the British Medical Association. He himself, as an unofficial ambassador of the Association, had had an amazingly kind reception.

Some discussion took place about travel arrangements, and the invitation was accepted with expressions of appreciation, the actual date of the meeting and other circumstances being left for later consideration and communication with South Africa.

Dr. Dain was reappointed for the ensuing year as the co-opted member representative of general practice on the Council of the Royal College of Surgeons of England.

Medical Certificates

Dr. Wand, as chairman of the General Practice Committee, presented for approval a statement of evidence on medical certification to be submitted to the Departmental Committee which was recently appointed by the Minister of Health to consider various aspects of this matter.

A highly detailed discussion on certain phrases in the preamble to the statement and on the recommendations followed, and certain slight amendments were made. The discussion broadened out into a wider channel over a reference in the statement to non-medical certification—that is to say, the increasing number of certificates which practitioners are asked to complete in support of applications for passports, replacement of ration books, old age pensioners' tobacco concessions, and the like. These certificates require to be witnessed or countersigned by members of certain classes in the community, such as barristers, schoolmasters, or doctors, and it is the experience of the profession that such certificates are brought more often than not to the doctor, and that in many cases certification involves an otherwise unnecessary visit to an applicant confined to his house. A recommendation was appended that practitioners should be relieved of this burden by the deletion of the profession from the classes of persons authorized to sign all such certificates.

Dr. R. W. Cockshut, Dr. P. J. Gibbons, and Dr. J. B. Miller spoke strongly against the inclusion of such a recommendation. Dr. Cockshut said that he liked signing certificates for these old people; it was a friendly gesture, it took up a very small amount of time, and it was part of that human side of medicine which they should encourage. Moreover, a visit from these old people for this non-medical purpose often caused the doctor to notice something wrong with them and it was possible to give them early treatment. Dr. Gibbons said that in many cases the doctor was the only person to whom these people could go. Dr. Miller asked whether they were to proclaim themselves less public-spirited than the other professions named in the Regulation. The inconvenience of witnessing these signatures was greater in the case of the members of the other professions than in the case of doctors, who were accustomed to certifying. The profession was tenacious of its privileges; it should be prepared for its liabilities.

Dr. F. Gray pointed out that where medical certificates were required doctors were the only people who could give them, but the certificates under discussion were not medical ones. If they were prepared to accept something which as a profession they need not do they were undermining the strength of their case on the general certification issue. Dr. C. M. Stevenson thought it should be realized that the profession's chief job was diagnosis and treatment, not certification.

A proposal to delete the whole of the reference was defeated, but the recommendation was amended to read that practitioners should be relieved of this burden "as far as possible." The statement of evidence with this and other slight amendments was approved.

Recruitment of Nurses

Dr. Mary Esslemont, in reporting for the Committee on Nursing, said that the Medical Superintendents' Society and the British Hospitals Association wished to be associated with the memorandum on the recruitment and training of nurses which had been prepared by the committee for submission to the Minister of Health. The Royal College of Nursing had stated its desire to submit its observations independently, and King Edward's Hospital Fund for London was unable to join the Association in sponsoring the memorandum as some of the matters dealt with were outside its province. Dr. Esslemont also said that the committee was considering the question of economy in the use of skilled nursing staff. It was difficult to bring about an actual increase in the total number of nurses, and therefore measures of economy were proposed.

Dr. E. C. Dawson suggested reviewing the position of private nursing, in respect of which he thought some economies might be effected, and Dr. MacFeat thought that greater economy of skilled nursing staff might be exercised by local authorities. Girls employed by local authorities as nurses were sometimes directed to duties which were largely clerical. Further, many nurses in hospitals on gaining experience were not stepped up in salary as they ought to be, and therefore some of them took higher-paid jobs outside the hospital.

The Care and Treatment of the Elderly and Infirm

Dr. Janet Aitken reported for the Committee on the Care and Treatment of the Elderly and Infirm. The committee thought that Regional Boards might be encouraged to adopt the proposals made in its report issued last year if their attention were drawn to the fact that the geriatric service recommended would have the additional advantage of increasing the numbers of beds and of skilled nurses available for the treatment of the acute sick. It had been decided to draw up a supplementary memorandum emphasizing the importance of this aspect of the matter.

Dr. J. G. Thwaites thought it a rather dangerous assumption to suppose, as might perhaps be inferred from the report to the Council, that elderly sick did not need highly skilled nursing. Dr. Aitken said that it was fully recognized that such nursing was required by certain elderly patients.

Reorganization of Scottish Branches

Dr. G. MacFeat, chairman of the Scottish Committee, gave an outline of the proposed reorganization of the Association in Scotland which the committee had been considering. The reorganization of the Scottish Branches had been undertaken to relate them to Regional Board areas for the purpose of establishing Regional Medical Committees. It was proposed that these regional medical committees be named "Regional Consultants and Specialists (including Hospitals) Committees," and that they be coterminous with the areas of the Boards under the Act. Their function would be to represent the views of the profession on hospital and specialist services and to maintain the interests of consultants and specialists under the new service. Dr. MacFeat described how the Branches would be grouped in the five regions, how the committees would be composed in order to make them fully representative, while leaving the exact method to local decision, and how the consultants and specialists in Scotland would be represented on the new standing committee of the Council. In accordance with the English analogy, the Scottish Committee was appointing a new Consultants and Specialists Subcommittee, and careful consideration had been given to its membership. Other matters considered had been the relationship of the areas of Divisions to Executive Council areas, with which in the majority of cases they already coincide, and the holding of a Scottish Representative Meeting at regular intervals.

Mr. A. M. A. Moore, chairman of the Consultants and Specialists Committee, said that the Scottish Committee deserved to be congratulated on the planning of this reorganizational machinery.

The report was approved.

and 1.5 g

Other Committee Reports

Several other reports of committees were adopted. The matters contained in the reports of the Insurance Acts and Public Health Committees, presented respectively by Dr. E. A. Gregg and Dr. James Fenton, have already been noticed in the reports of the proceedings of those committees. Reports from the Central Ethical Committee and the Consultants and Specialists Committee, presented respectively by Dr. N. E. Waterfield and Mr. A. M. A. Moore, dealt with routine business. A report from the Dominions Committee was presented by Dr. J. B. W. Rowe. At a previous meeting of the Council this committee had reported that it had received a protest from the British Guiana Branch regarding an ordinance made in the colony on the subject of workmen's compensation. The ordinance, after prescribing the fees to be paid to practitioners for emergency treatment rendered to injured workmen, provided a penalty of fine or imprisonment in the case of a practitioner who failed to respond to a call for such emergency treatment. The committee was now able to report that, after representations to the Colonial Office, this penal clause had been repealed.

Dr. J. A. L. Vaughan Jones introduced a brief report from the Industrial Medicine Committee which stated that the recommendations on the duties and ethical rules of industrial medical officers were being brought up to date in the light of recent developments. Another present task of the committee was the obtaining of information about schemes of occupational health in foreign countries. The information was being submitted to a subcommittee which had been appointed to prepare a draft scheme for an occupational health service.

Reports from the Journal Committee (Dr. O. C. Carter), Building Committee (Mr. Moore), and Charities Committee (Dr. Janet Aitken) were approved.

A recommendation of the Group of Venereologists at its inaugural meeting was approved—namely, that the Group Committee should consist of twelve members elected by members of the Group on a national basis with the addition of the President of the Medical Society for the Study of Venereal Diseases as an *ex-officio* member, and with power to co-opt.

The Council received with regret an intimation from Dr. I. Revans, Assistant Secretary, that he wished to resign his post on accepting an administrative appointment with the South West Metropolitan Regional Board. Mr. A. M. A. Moore testified to the excellent work which Dr. Revans had done a secretary to the Consultants and Specialists Committee.

The Talks at the Ministry

The routine business of the Council having concluded Dr. Dain, from the chair, gave some account of happening since the special meeting of the Council held during the previous week. On instruction from the Council the invitation to Sir William Douglas to assist in formulating an Amending Bill was accepted. A meeting had taken place with the officers of the Ministry, who were duly informed about the matters which in the view of the Council, the Amending Bill should contain. It had not yet been possible to fix a date for the meeting with the Minister, but they would arrange to see him soon. His officers made the statement that the Minister was prepared to introduce an Amending Bill within the terms of his statement in the House of Commons. He thought that they could get by argument the effective removal of the basic salary. He hoped they would be able to remove anything in the way of direction of practitioners from the Medical Practices Committee. The deputation then took up with the officers certain other problems, including the size and distribution of the general practitioners fund, and the size of the compensation fund. The deputation suggested that there should be no global sum for compensation but an agreement to pay what was necessary on a formula of individual practice values. On the capitation fee they had said definitely that they would require the capitation fee for services to be on a fixed basis, like the insurance capitation fee to-day, and that mileage should be provided for separately. They had also emphasized that it was essential before July 5 that consultants and specialists should have a firm knowledge of what they might expect in the way of conditions of service. Dr. Dain added that there

were a very large number of people in the profession who had yet to be satisfied before they would willingly enter the Service, and it was important to make the Minister fully aware of the serious objections which were outstanding.

There was some discussion on Dr. Dain's statement.

On the motion of Mr. A. M. A. Moore, Mr. Dickson Wright was added to the membership of the deputation meeting the Minister.

CONSULTANTS AND SPECIALISTS ORGANIZATION

We reprint from the Annual Report of Council (April 10, p. 77) the section on the formation of Regional Consultant and Specialist (including Hospitals) Committees, and establishment of a Central Consultants and Specialists Standing Committee.

CONSULTANTS AND SPECIALISTS

Formation of Regional Consultant and Specialist (including Hospitals) Committees, and establishment of a Central Consultants and Specialists Standing Committee

60 The Council has given detailed consideration to the steps which should be taken by the Association to enable the profession to deal with problems arising in the consultant and specialist and hospital fields consequent on the formation of Regional Hospital Boards. The problem before the Council was whether, and if so in what manner, the existing machinery of the Association could be adapted for this purpose; or whether it would be necessary to set up an entirely new piece of functional machinery which, although not forming part of the Association's constitution, should be linked with the Association at the centre and possibly also at the periphery.

Need for Formation of Regional Consultants and Specialists (including Hospitals) Committees

The Council believes that there will be general agreement with the idea that in the area of each Regional Hospital Board a professional committee should be set up to represent the views of the profession on hospital and consultant and specialist services in the Region. There is no statutory provision for setting up such a regional committee, and to this extent the position differs materially from that which applies in the field of general practice where there is provision under the Act for the formation and recognition by the Minister of Local Medical Committees which represent the profession in local areas, and include elected members of Local Executive Councils. The Council is of opinion that Committees on somewhat parallel lines to Local Medical Committees should be formed in the areas of Regional Hospital Boards. The Council suggests that the proposed new bodies should be designated Regional Consultants and Specialists (including Hospitals) Committees.

If these regional committees are to command the confidence of consultants and specialists, a majority of the members of each committee must be elected by practitioners engaged in consultant and specialist practice, and separate representation must be given to those of full medical staff status who are or have been employed by teaching hospitals or by non-teaching hospitals and are in consultant and specialist practice within the Region. The Council proposes that not less than one-quarter of those elected to regional consultant and specialist committees by the staffs of non-teaching hospitals should be part-time consultants and specialists—i.e., those engaged partly in consultant and specialist practice and partly in some other form of professional work. Further, in order that there may be correlation of the work of regional consultant and specialist committees with other bodies providing services under the Act there should be representation on these committees of Local Medical Committees, of medical officers employed whole-time by the local authorities in the Region, and of medical superintendents of hospitals within the Region. The regional committee should also have power to co-opt, say, up to three additional persons. In some Regions it may be necessary to secure the election of representatives of senior medical officers of the staffs of local authority hospitals transferred to Regional Hospital Boards, and special consideration will be given to this point.

The Council has given very careful consideration to the method of election of the members of regional consultant and specialist committees. If this new piece of functional machinery is to succeed it is essential that practitioners working in the consultant and specialist fields should have a direct interest in the election of the committee and in its work. In the view of the Council it would not suffice if the nomination and election of members of the committee was conducted by postal vote from a list of the members of the staffs of teaching and non-teaching hospitals. For the first year at all events the mode of election of practitioners to the regional consultant and specialist committees should be on the principle of representation of hospital staffs or groups of hospital staffs. The precise method of giving effect to this plan would be a matter for discussion with members of hospital staffs concerned in order that a practical scheme may be worked out in respect of each Region.

When the regional consultant and specialist committees have been constituted they would be invited to consider the problem further, in the light of the experience of the first election, and to make proposals for permanent machinery for future elections.

As these regional committees will represent in their respective areas the general body of consultants and specialists, they should be elected irrespective of membership of the British Medical Association. This will follow the parallel of Local Medical Committees and will lead to the position that the proposed new functional machinery will not form an integral part of the Association's constitution. But if there is to be effective co-ordination of the work of regional committees it is fundamental that a close relationship between these committees and the Association should be secured. Regional consultants and specialists committees must be encouraged to look to the Association for guidance and help upon the problems which will arise with the working of the Act, and major questions of policy should be determined by the Association.

For the reasons stated in the preceding paragraph of this report the Council has decided that steps should be taken forthwith by the Association to set up in the areas of Regional Hospital Boards in England and Wales regional consultants and specialists (including hospitals) committees, representative of members of the Association and of non-members alike. Action on these lines will not apply to Scotland until the Scottish Committee has reported to the Council.

Constitution of Regional Consultants and Specialists (including Hospitals) Committees

61 The detailed constitution of the regional consultants and specialists (including hospitals) committees for England and Wales are as follows:

- (i) 2-5 elected by practitioners engaged in consultant and specialist practice and who are either—
 - (a) members of the consultant and specialist staff of teaching hospital(s) within the Region, or
 - (b) have been members of the consultant and specialist staff of such hospital(s) and are in consulting or specialist practice in the Region.
- (ii) 12-20 (of whom not less than a quarter shall be part-time consultants or specialists, i.e., those engaged partly in consultant or specialist practice and partly in some other branch of medical practice in the Region) elected by those practitioners engaged in consultant and specialist practice and who are either—
 - (a) members of the consultant and specialist staff of a hospital, other than a teaching hospital within the Region, or
 - (b) have been members of the consultant and specialist staff of a hospital other than a teaching hospital and are in consulting or specialist practice in the Region.
- (iii) 2 medical officers of health elected by medical officers employed whole-time by Local Authorities in the Region.
- (iv) 1 medical superintendent elected by medical superintendents in the Region.
- (v) 2 general practitioners elected by grouped Local Medical Committees within the Region.
- (vi) With power to co-opt not more than 3 additional members, e.g., practitioners of First Assistant or Registrar status.

Notes

(a) The term "consultant and specialist" means those of full medical staff status who are, or have been, employed at a teaching or non-teaching hospital.

(b) The number of members of the Regional Consultants and Specialists Committee in (i) and (ii) above are provisional

in respect of the first year's working of the committee, and would be varied, and where necessary increased, according to the circumstances existing in the Region.

(c) The first Regional Consultants and Specialists Committees will be invited to consider their constitution and to make recommendations for placing the local organization on a more permanent basis.

(2) That the mode of election of practitioners in (i) and (ii) above be on the principle of representation of hospital staffs, or of groups of hospital staffs.

(3) That the method of election of all groups shall be devised separately by such Region.

(4) That the functions of the Regional Consultants and Specialists Committees should be to represent the views of the profession on hospital and consultant and specialist services in the Regions. It should also keep the Central Consultants and Specialists Committee fully informed and be guided by that Committee on matters of general policy.

(5) In so far as clerical facilities are provided by the Association in the Region these will be made available to Regional Consultants and Specialists Committees, the cost being borne by the Association. Other costs such as individual members' travelling expenses will be borne by the committee.

The Relationship of Regional Consultants and Specialists Committees to the Association

62. The Council has given careful consideration to the relationship of regional consultants and specialists committees to the Association and the extent to which it may be necessary to modify or adapt the Association's constitution to meet the position. There are two problems, local and central.

The Local Problem

It is clear that the Divisional machinery cannot appropriately be used for the purpose of linking regional medical committees with the Association.

Branches of the Association cover areas of one or more counties and parts of counties. In one instance (North of England Branch) the area of one Branch is approximately coterminous with that of a Hospital Region; in another (Lancashire and Cheshire Branch) the Branch area is approximately coterminous with that of two Hospital Regions; in the Welsh Region there are two Branches with part of another Branch. With these exceptions Branch areas have little relation to Hospital Regions. The Council has come to the conclusion that the Branch machinery, so far as it relates to England and Wales, cannot effectively be used in connexion with the work of the regional consultants and specialists committees, but it feels that at present at all events the existing Branch organization should not be disturbed and that the position of the Branches should be reviewed from time to time in the light of developments.

The Central Problem

There are at present two standing committees, Consultants and Specialists, and Hospitals, which deal respectively with problems affecting consultants and specialists and hospitals.

The Council is of opinion that it will be necessary to set up a Central Consultants and Specialists Committee in place of the present Consultants and Specialists and Hospitals Committees. The function of the proposed new committee would be to consider matters specially affecting those engaged in consulting or specialist practice, including matters referred from regional consultant and specialist committees, and all questions concerning hospitals.

A majority of the members of the new standing committee should be elected by regional consultant and specialist committees and by consultants and specialists in Scotland in a manner yet to be determined, and this majority representation should consist of those who are engaged exclusively or predominantly in consultant or specialist practice, whether or not they are members of the Association. A similar position obtains in the case of the Insurance Acts Committee, where the majority of members are directly elected by Local Medical and Panel Committees, irrespective of their membership of the Association. The Consultants Roll and the Part-time Consultants Roll would be discontinued.

The existing arrangement under which each group committee appoints a representative to the Consultants and Specialists Committee should be continued. The twelve groups consist of members who have distinctive professional interests (e.g., anaesthetists, ophthalmologists, radiologists) who by reason of their numbers are unable to obtain adequate representation of those interests through the ordinary Division machinery, and it is important that the views of the groups, as represented through their respective group committees, should be brought to the new standing committee by means of direct representation.

Practitioners engaged in part-time consultant and specialist practice should also be represented on the committee, and it is suggested that there should be five such members nominated and elected by those members of regional consultant and specialist committees who are themselves part-time consultants or specialists.

The Council suggests that the other members of the new committee should be the officers of the Association; four elected by the R.B. (who should be engaged predominantly or exclusively in consultant and specialist practice), two members by the Council, four members appointed by the Insurance Acts, General Practice, Public Health, and Industrial Medicine Committees respectively, and that there should be power to co-opt. The new Central Consultants and Specialists Committee should also have power to elect a member to each of these standing committees.

These proposals will involve the establishment of a large standing committee, but it is the considered view of the Council that it would be unwise so to reduce the number of members of the committee that it might be held not to be fully representative of the interests of consultants and specialists.

The Council submits in para. 126 of this report the appropriate amendments to the By-laws and to the Schedule to the By-laws to give effect to the above proposals so far as they relate to the Central Consultants and Specialists Committee. The proposals for regional committees involve no amendments to the By-laws.

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

Metropolitan Borough Councils.—Fulham, Hackney, Poplar

Non-County Borough Councils.—Dartford, Radcliffe (limited to future appointments), Tottenham, Wallsend.

Urban District Councils.—Denton, Droylsden, Houghton-le Spring, Huyton-with-Roby, Portslade, Redditch (restricted to new appointments), Tyldesley.

Scottish Burghs.—Motherwell and Wishaw.

Association Notices

Diary of Central Meetings

JUNE

3 Thurs. Publishing Subcommittee, 11 a.m.

Branch and Division Meetings to be Held

BOURNEMOUTH DIVISION.—At Royal Victoria and West Hants Hospital, Bournemouth, Monday, May 31, 8.15 p.m. Ordinary and Special Meeting of the Division. Agenda includes installation of Dr. O. C. Carter as Chairman; adjournment; Special Meeting to receive report of Representatives to Special Meeting of the Representative Body on National Health Service Act; instruction to Representatives to A.R.M. at Cambridge on June 25. All medical practitioners in the area of the Division are invited.

METROPOLITAN COUNTIES BRANCH.—At B.M.A. House, Tavistock Square, London, W.C., Tuesday, June 1, 2.30 p.m. Ninetieth Annual General Meeting. Agenda: Report of Branch Council for 1947-8; report of Branch representatives on Central Council, 1947-8; election of officers for 1948-9; address by incoming President.

WINCHESTER DIVISION.—At Royal Hotel, Winchester, Wednesday, May 26, 7.30 p.m. Annual general meeting. Consideration of Annual Report of Council, 1947-8, and three resolutions on N.H.S. Act; 8.50 p.m., dinner; 9.45 p.m., film: "Dear Octopus."

PNEUMOCONIOSIS OF COAL-MINERS*

BY

C. M. FLETCHER, M.D., F.R.C.P.

Director, Pneumoconiosis Research Unit, Medical Research Council

[WITH PHOTOGRAPHURE PLATE]†

In South Wales during the past 15 years rather more than 17,000 men have been certified by the Silicosis Medical Boards to be suffering from silicosis or pneumoconiosis and have been suspended from their underground work. More than 10,000 of them have been certified in the past three years. There were two mines in South Wales which lost one in every three of their underground workers owing to these diseases in the one year 1945. These bare figures need no embellishment to reveal the seriousness of the problem presented to the mining industry or to convey the extent of human suffering occasioned by pneumoconiosis in this region. Elsewhere in Great Britain the problem is proportionately less serious, but even here the certification of nearly 3,000 men in 15 years presents a problem that is serious enough.

In 1943 a committee was set up by the Minister of Fuel and Power to consider the rehabilitation and treatment of miners in South Wales suffering from silicosis and pneumoconiosis. Among the recommendations of this committee (Ministry of Fuel and Power, 1944) was that more research into the problem was needed. The Medical Research Council was approached, and in 1945 it established in South Wales a Pneumoconiosis Research Unit to carry out investigations into every aspect of the problem of coal-miners' pneumoconiosis. Since then it has been my concern to organize and carry out research with a growing team of medical and other scientists in this Unit.

I propose, first, to consider briefly how the present disastrous situation has arisen in a century remarkable for the important advances in industrial health which have been achieved in almost every industry, then to discuss the former investigations of the Medical Research Council into the problem and the developments that have taken place since their publication. Finally, I shall describe some of the recent investigations undertaken by the Pneumoconiosis Research Unit and others in South Wales.

History

The early history of coal-miners' pneumoconiosis is rather obscure. The pathology of the disease was described in this country over 100 years ago in Scottish coal-miners by Gregory (1831), Marshall (1834), and Thomson (1836), and the associated clinical descriptions of the breathlessness,

which was called miners' asthma, and the black spit of such cases exactly match the clinical picture as we see it to-day. Greenhow's demonstration of the siliceous residues in the lungs of such cases in 1869 carried knowledge a step further, but thereafter the subject lapsed into obscurity, with a general consensus of opinion developing in the first two decades of this century that, owing to the improved conditions in the pits, the disease no longer existed among coal-miners (Oliver, 1908). This opinion was expressed by two successive Milroy lecturers. Thus Shuffebotham in 1914 said, "At the present time in Great Britain fibrosis of the lungs among miners can be said to be practically non-existent"; and in 1915 Collis said, "Miners' asthma, common though it used to be, has passed unobserved from our midst, and conjectures as to its character and causation are idle."

Whether these opinions were correct or not we cannot now be sure, but some doubt is thrown on them by a consideration of the Registrar-General's returns in the first four decennial supplements of this century. Unfortunately, we cannot go further back than this because of the unsatisfactory occupational classifications previously in use. However, for these four periods Mr. Oldham, our statistician, has calculated mortality rates (standardized on the population of all occupied and retired males in England and Wales, 1901) from all respiratory diseases other than tuberculosis and from pulmonary tuberculosis for coal-miners over and under the age of 55; for it is in the older coal-miners that deaths from pneumoconiosis are most likely to occur. These standardized rates are given in Table I, together with the rates from the same causes for

TABLE I.—Standardized Death Rates of Coal-miners and All Occupied and Retired Males in England and Wales, per 1,000

	Period	All Respiratory Diseases except Tuberculosis				Pulmonary Tuberculosis			
		1900-21	1910-12	1921-3	1930-2	1900-21	1910-12	1921-3	1930-2
Over 55	Coal-miners ..	21.33	14.21	13.60	7.02	1.82	1.27	1.14	0.86
	All occ. and ret. males, E. & W.	14.24	9.91	8.96	5.16	2.17	1.85	1.26	1.04
Under 55	Coal-miners ..	1.57	1.05	1.00	0.50	1.14	1.01	1.06	0.95
	All occ. and ret. males, E. & W.	1.93	1.14	1.00	0.76	2.64	1.96	1.50	1.24

*The first of the two Goulstonian Lectures delivered at the Royal College of Physicians of London on Jan. 13 and 15.

†The Photographure Plate will appear in next week's issue, with Lecture II.

all occupied and retired males. Coal-miners over 55 have throughout this period consistently shown a relatively high death rate from all respiratory diseases other than

tuberculosis. Although Oliver's (1908) evidence of a diminishing incidence of pulmonary fibrosis among coal-miners towards the end of the last century is convincing, I suspect that considerable numbers of these deaths have always been due to dust diseases of the lung, and that the supposed disappearance of the disease was in part due to incorrect diagnoses.

The relatively low death rates of coal-miners from tuberculosis are also shown in Table I. It was perhaps this fact more than anything else which led to the widespread and persistent acceptance of the view that silicosis was rare among coal-miners; for the particular liability of the silicotic to die from tuberculosis had become established in this century, especially as a result of J. S. Haldane's important contributions to the subject. It was Haldane (1934) who defined silicosis as "a disease of the lungs brought about by the inhalation of siliceous dust and leading to tubercular infection of the lungs accompanied by a great development of fibrosis in them." From this definition the reverse conclusion was derived that when in any industry there was no excessive tuberculous mortality there was no silicosis. Haldane's (1923) declaration that "the inhalation of coal dust causes no danger to life but on the contrary gives even protection against the development of tuberculosis" was largely responsible for the fact that mining engineers made no attempt to reduce the concentrations of air-borne coal dust in the mines at a time when, owing to the introduction of mechanical methods of mining, these concentrations were in general becoming more intense. It must be admitted that medical men by their ill-informed complacency have a heavy load of responsibility to bear for the present high incidence of pneumoconiosis among coal-miners.

This period of complacency was closed chiefly by the increasing use of radiography in the diagnosis of chest disease. Cases of definite silicosis in coal-miners who had carried out drilling in rock were first reported in South Wales in 1926 by Tattersall. Soon after this, in South Wales, tuberculosis officers of the Welsh National Memorial Association (1931) and private radiologists, in particular Harper (1934) in Ammanford, began to observe radiological pictures similar to silicosis in coal-miners who would have been diagnosed clinically as cases of chronic bronchitis, and even in apparently healthy miners. In 1930 Cummins and Sladden in a classical paper published a detailed account of the pathology of such cases, showing that they had a kind of silicosis modified by what was regarded as an accumulation of coal dust due to lymphatic blockage by silicotic fibrosis.

The South Wales Miners' Federation had naturally been claiming compensation for men such as these for some years, but it was not until 1929 that a scheme of compensation was started. Initially, the scheme was confined to men who could prove that they had worked in silica rock, but in 1934 it was opened to all men working in coal. The rising number of certified cases in South Wales soon showed that pneumoconiosis was a serious problem, at least in the anthracite mines in this coalfield. At the same time, in Sweden (Edling, 1926), Germany (Boehme, 1925), Belgium (Langelcz, 1938), France (Magnin, 1935), and also in Australia (Badham and Taylor, 1933) reports of silicosis among coal-miners were appearing. In America (Bloomfield *et al.*, 1935; Flinn *et al.*, 1941; Jones, 1942), and later in the Soviet Union (Moshkovsky, 1941), the disease was also shown to exist, chiefly among anthracite miners.

In England, however, uncertainty concerning the nature of the disease among coal-miners persisted. Haldane's (1935) view was that coal-miners developed bronchitis because of the excessive pulmonary ventilation occasioned

by their strenuous work, and that consequently inhaled coal dust was not normally eliminated from their lung and accumulated to cause a benign type of fibrosis which was not silicotic. Jones (1936) added the suggestion that bronchitis was especially common among anthracite miners because they become chilled after their day's work by being brought to the surface in special open cars or "spakes," whose use is almost entirely confined to this part of the coalfield.

M.R.C. Inquiries—Medical Studies

It was against this background of increasing awareness of the prevalence of some form of pulmonary fibrosis among coal-miners that the Industrial Pulmonary Disease Committee of the Medical Research Council undertook to investigate the problem in South Wales. These investigations began in 1937, and their results were published in three reports appearing in 1942, 1943, and 1945.

Between 1938 and 1940 Hart and Aslett carried out a radiological survey of working colliers at 16 pits distributed throughout the South Wales coalfield. Their main conclusions were:

First, that there was a serious incidence of radiological abnormalities among coal-face workers, similar to those seen in cases of silicosis, which must be attributed to the inhalation of coal dust. Although men exposed to the inhalation of rock dust were more prone to develop these abnormalities it was among the numerically predominant coal-getters that the greatest number of cases occurred. The part played by coal dust was further illustrated by confirming the presence of similar abnormalities in the lungs of coal-trimmers exposed to dense clouds of coal dust, but to no rock dust, in the bunkers of ships in South Wales ports, thus confirming the findings of Collis and Gilchrist (1928).

Secondly, that the incidence of the disease appeared to be related to the type of coal in which the men worked. They confirmed the evidence provided by figures of certification that hewers of anthracite in the western part of the coalfield were most seriously affected, that hewers of soft or bituminous coal were much less affected, and that hewers of steam coal with its intermediate rank showed an intermediate incidence. This observation gave rise to what may be called the "rank of coal" hypothesis, which relates incidence of pneumoconiosis to rank of coal. The "rank" of a coal is measured by the proportion of carbon and hydrogen in the coal substance. A high rank or hard coal has a high proportion of carbon (as in anthracite) while in softer coals the proportion of hydrogen increases and that of carbon diminishes. There were a few anthracite (high rank) pits which did not show a high incidence, but these exceptions were explained by the fact that they were shallow pits in which the coal was naturally damp and therefore less dusty.

Thirdly, they described an appearance in the abnormal radiographs of a "fine network, sometimes sharp and lacelike in pattern, but much more often blurred in appearance," which they called *reticulation*. This condition was clearly occupational in origin and might be associated with respiratory disability, but, not being nodular in appearance, did not conform to the criteria of silicosis required for compensation purposes. The Industrial Pulmonary Diseases Committee consequently recommended that for the purposes of compensation the radiological standard required for the diagnosis of "pneumoconiosis of coal-miners" should include reticulation. Subsequently an order was issued to this effect, and on and after July 1, 1944 the radiological condition of reticulation was made certifiable.

"Reticulation"

I want at this point to make a few comments on the introduction of the term "reticulation," for some confusion has arisen from its use and from the description of its appearance as being that of a network. Hart and Aslett admitted in their full discussion of this question that

reticular pattern, or an increase of linear lung markings, had been described by other observers (e.g., Steuart, 1923; Edling, 1926) in the early stages of silicosis which precede the formation of definite nodular shadows and which were considered by many of them to be non-specific changes that might be seen in cases without any dust exposure, particularly in patients with chronic bronchitis. Hart and Aslett considered that reticulation was distinct from the appearance of exaggerated lung markings in that it was a finer pattern and did not fade at the periphery of the lung fields. Confusion has, however, persisted. For instance, in France, where periodical x-ray examinations of all underground workers in coal-mines have recently been instituted, the term reticulation is used to describe non-specific changes (Croizier, 1947). In South Wales many men are referred by their doctors to the Silicosis Medical Boards with a radiological opinion that they have reticulation when their radiographs show only an increase in lung markings. Moreover, "reticulation" has come to be used, even in this country, to describe the earliest stages of classical silicosis (Hale, 1946) and other occupational lung diseases (Perry, 1947). Whatever may be the merits of the word "reticulation" to describe the characteristic pattern of early coal-miners' pneumoconiosis, there is no doubt that in practice its use may give rise to some misunderstanding.

Hart and Aslett were forced by circumstances to use a portable x-ray set for their radiography and were therefore unable to achieve a high degree of definition in their films. In the Pneumoconiosis Research Unit we have been fortunate in having a fine-focus rotating anode tube, and we have used ordinary films and high-definition screens. With this technique we find that the most characteristic and almost universal change in the disease is a fine mottling whose main components are usually less than 1 mm. in diameter but may reach twice that size. For this appearance we have, for the time being, used the term "pin-head mottling". In the earliest stages it appears alongside and between exaggerated lung markings, but later it may become so intense that it obscures the normal markings completely (Plate, Fig. 1). The appearance is similar to that described by Caplan (1947) in silicosis in the Kolar gold-mines. It is uncommon for this pin-head mottling to remain in a pure form. Frequently it is associated with a coarser mottling, through which it can still be distinguished, so that a film is often seen which appears nodular when viewed at a distance of a few feet but in which, on closer scrutiny, the nodules can be seen to be composed of aggregates of pin-head mottling (Fig. 2). These granular nodules may be distinguished from a more homogeneous type of nodule which we see particularly in cases resembling classical silicosis with a history of heavy exposure to rock dust or in cases where we suspect a complicating tuberculosis. The commonest type of film is one in which there is a mixture of pin-head mottling with rather coarser nodular shadows of irregular shape and size (Fig. 3). We are not inclined to use the word "network" to describe any of these appearances. We do not suggest that at present the term "reticulation" should be abandoned. It has proved useful in emphasizing the differences between the early stages of coal-miners' pneumoconiosis and those of classical silicosis, and it can only be supplanted by some better term as a result of wide agreement among workers in the field of pneumoconiosis. Moreover, it may be that, with further advances in radiographic technique, further modifications in terminology may become necessary.

Verbal descriptions of radiological appearances, however, will always be confusing. We think they should be forsaken and that in their place should be built up a national (perhaps ultimately international) collection of type films. These films, or good reproductions of them, should be

made available to all medical men concerned with the study of pneumoconiosis. Any radiological appearance could then be described without risk of misunderstanding as being similar to a particular area of a given standard film.

A more serious practical difficulty than that of terminology arises from the fact that reticulation has to be considered as a definable condition for the purpose of decisions concerning compensation. It is obvious that the condition must in fact gradually develop from normality, but, unlike nodulation, in which it may be possible to define a minimum number and size of nodules for such purposes, reticulation cannot be assessed numerically, and it appears to develop only by a gradual increase in intensity. Hart and Aslett gave no guide to the degree of abnormality required for a confident diagnosis of reticulation to be made.

I have recently explored this question experimentally by presenting x-ray films showing various degrees of reticulation to a number of experienced observers, and have found remarkable differences in their opinions concerning the minimal degree of abnormality required to justify a diagnosis of reticulation.

This quantitative aspect of diagnosis is an artificial one resulting from the requirements of compensation legislation. The difficulty might be resolved by the use of standard films (taken, of course, with standard technique) for comparison with any film that is under consideration. I propose to repeat my experiment on diagnosis using such standards, in order to see what increase in consistency of opinion can be obtained with their assistance.

To return now to Hart and Aslett's conclusions. In the fourth place, they described a sequence of radiological abnormalities beginning with reticulation and proceeding through nodulation (consisting of localized or generalized multiple discrete shadows 2 to 5 mm. in diameter) to coalescent nodulation in which the nodular shadows begin to fuse, and on to the late stages of multiple fluffy shadows consisting of larger, less well-defined shadows than those of nodulation, and finally to large, well-defined, and dense massive shadows. From a consideration of the varying incidence of these abnormalities in men with increasing exposure to coal dust they postulated that with such continued exposure, at least in the mines with higher incidence, reticulation tended to develop into nodulation and thence by coalescence to fluffy and massive shadows. Consideration of the underlying pathology of these radiological appearances led to the conclusion that reticulation and the later more advanced abnormalities were "related in pathological development as well as being connected in time sequence." They carefully considered the part that tuberculosis might play, but concluded that it was so modified by pneumoconiosis that its presence could not be identified confidently in life and that it played an associated rather than a causative part. This view that a modified tuberculosis might play an adjuvant rather than an essential part in the development of massive fibrosis was similar to the views of Cummins (1936), Sen (1937), and Jones (1938) in South Wales. It differed slightly from the American view (Sokoloff, 1936; Bloomfield *et al.*, 1935; Gardner, 1940), by which tuberculosis appeared to be regarded as entering into and modifying the majority of the cases of advanced fibrosis. It was opposed to the view of Policard (Policard *et al.*, 1939), in France, who has always maintained that tuberculosis is the main cause of fibrosis in pneumoconiosis.

Lastly, finding no particular method of mining to which the high incidence of the disease might be attributed, Hart and Aslett emphasized the urgent need for suppression of all airborne dust in coal-mines.

M.R.C. Studies of Pathology and Pathogenesis

In the same report there appeared an account by Belt and Ferris (1942) of the pathology underlying the x-ray changes described by Hart and Aslett. They were not able to add much to existing accounts of the disease

(Cummins and Sladden, 1930; Gough, 1940), but they laid emphasis on a basic pathological change underlying the radiological reticulation which they described as a diffuse network of reticulin fibrosis enmeshing, without redundancy, the deposits of coal dust in the lungs. To this condition they gave the name "dust reticulation." After ashing, dust reticulation left a highly siliceous residue. It provided a constant background, as does radiological reticulation, to the more advanced collagenous fibrosis corresponding to radiological appearances ranging from nodulation to massive shadows. Belt and Ferris suggested that the dust reticulation was due solely to the presence of silica in the coal dust, but that the development, in certain cases only, of collagenous fibrosis was due to the sporadic influence of an additional factor. This factor was not identified, but it was suggested that it might often, though not necessarily always, be the tubercle bacillus. This suggestion was based on the histological similarity between many of the fibrotic lesions in which tubercle bacilli could be identified and others in which they were not to be found but might none the less have been present at an earlier stage in the development of the lesion.

The pathogenesis of the disease was investigated along three main lines in addition to that of morbid histology.

A. By studies of air-borne dust underground in the mines at which radiological surveys had been carried out (Medical Research Council, 1943). It was shown that there was a relationship between disease incidence and the concentration both of the total dust and of its ash (or non-coal) component. It was not possible to distinguish between the quantitative and qualitative effects of the various dusts, but in their summary of the findings the Industrial Pulmonary Diseases Committee concluded that "the dust in anthracite mines is more dangerous than in the bituminous mines," thus supporting, but not explaining, the rank-of-coal hypothesis.

B. By chemical and mineralogical studies of the residues obtained by incineration of lung specimens an attempt was made by King and Nagelschmidt (1945) to see whether the degree or type of fibrosis could be correlated with any particular component of the dust in the lungs. In the lungs of men who had worked predominantly in rock and who had developed the classical type of silicotic nodulation there was a significantly greater amount of quartz and mica than in lungs showing the other types of fibrosis, but amongst the latter group, while there was rather more quartz and mica in the more advanced cases of fibrosis, the difference from the earlier cases was not statistically significant. No correlation was found between the amount of fibrosis and the amount of coal, which led to the conclusion that coal itself was not fibrogenic.

C. By the intratracheal inoculation of rats with suspensions of various air-borne dusts and of dusts obtained by the grinding of certain rock strata encountered in the South Wales coal-measures Belt and King (1945) showed that dusts containing high proportions of quartz and mica were the most fibrogenic. Air-borne dusts in general gave little fibrosis. The most fibrogenic air-borne dust was, curiously enough, derived from a low-incidence bituminous mine.

On the other hand, Campbell (1944) exposed mice to the inhalation of anthracite and bituminous dust and found that a greater increase of reticular tissue was produced in the lungs with the former than with the latter dust.

The state of knowledge concerning coal-miners' pneumoconiosis as it was left after the publication of the Medical Research Council's Reports may be very briefly summarized as follows: There was now no doubt that pulmonary disease attributable to the inhalation of coal dust was a serious problem among the coal-miners of South Wales; that the frequency of its occurrence appeared to be related to the rank of coal, being higher in the higher-rank coal-mines, but whether this was due to quantitative or qualitative differences in the air-borne dust clouds could not be decided; and, lastly, that both silica and some unspecified

agent, possibly tuberculosis, were chiefly responsible for the development of fibrosis.

On the scientific aspect of the problem, the chief developments after the completion of the Medical Research Council's earlier investigation were in the field of pathology which I shall discuss later.

In the field of practical affairs, two developments need consideration: dust suppression, and an increase in the incidence of certified disease.

Dust Suppression

After the passing of the Coal Mines Act in 1911 the use of some device to prevent the escape of rock dust into the air during drilling became obligatory, but no attempts were made to suppress coal dust. In 1938 the Royal Commission for Safety in Coal Mines discussed suppression of coal dust only as a means of reducing the danger from explosions. Research into the problem was, however, advised, and the British Coalowners Research Associations and the Safety in Mines Research Board began to investigate the problem. In South Wales, as the results of the Medical Research Council's investigations came to be known, serious attention began to be paid to the prevention and suppression of coal dust underground, both by the Mines Inspectorate, the Monmouthshire and South Wales Coal Owners' Association, and by the Amalgamated Anthracite Company, who set up their own Silicosis Research Committee.

The result has been the development of various methods of dust suppression, of which the most important are the following

1. *Improvements in Ventilation.*—This has been of importance particularly in anthracite mines, where, owing to the methods of working the coal in common use, and owing to the rather haphazard development of the mines from shallow surface workings, poor ventilation was formerly one of the main reasons for the high dust concentrations in this part of the coalfield.

2. *Water Infusion.*—By this method water is introduced under pressure into the coal seam in advance of the working face, so that the coal is already damp when it is cut. It is a most effective method, but is not free from technical difficulties, particularly if the water leaks out from the coal seam into the adjacent strata, which it may soften and thus cause difficulties in the control of the roof.

3. *Wet Cutting.*—The mechanical cutting of coal has since its introduction been one of the most prolific sources of dust. A chain of picks is carried by a jib into the coal seam and undercuts or overcuts it, so that the coal is more easily won. The cutting of coal produces a mass of finely ground coal, much of which subsequently becomes air-borne, particularly when it is shovelled on to a conveyor. The introduction of water or foam with the picks damps the finely ground coal and largely prevents it from becoming air-borne, while percolation of the water into the coal adjacent to the cut and the dampness of the floor reduces much of the dust caused by working the overhanging coal.

4. *Water Sprays.*—Where water infusion or wet cutting is impracticable, water sprays are used to wet the coal-face before the coal is pulled down and the loose coal before it is loaded or before it is transferred from one conveyor to another or from a conveyor into trams. They have also recently been applied to pneumatic picks, which are another important source of dust.

The magnitude of the task achieved in the field of dust suppression in South Wales is shown by Table II, which gives the

TABLE II.—Extent of Dust Suppression in Coal-mines in Great Britain in November, 1947

	South Wales		Rest of Gr. Britain	
	Miles	% of Total	Miles	% of Total
Total length of coal-faces worked ..	80.51	100	306	100
Total length of faces with dust suppression in operation	42.6	53	12.5	4
Length machine-cut wet ..	14.6	18	8.6	2.7
Length water-infused ..	17.3	21.5	0.2	0.1
Length treated with hand-sprays ..	10.7	13.5	3.7	1.2

position of dust suppression in November, 1947. In South Wales half of all the coal-faces were treated with some means of dust suppression, and this is claimed to represent nearly all the places at which dust concentrations rise above the

PNEUMOCONIOSIS OF COAL-MINERS

provisional standards of safety that have been adopted. It will be seen that dust suppression in the rest of England is still in its infancy. Dust Prevention Committees have recently been set up in every division of the British coalfields, and the fruit of their labours should soon become apparent.

In this field, however, it is the doctor's role not to ask over how many miles of coal-face measures of dust prevention are officially being applied; he must ask, rather, how far dust levels are in fact being reduced. There is good evidence that in many places dust levels have been reduced to as little as 10% of their former high level, although all too often this degree of success has not been achieved (Monmouthshire and South Wales Coal Owners' Association, 1945). Whether this reduction is sufficient to remove the risk of pneumoconiosis is not yet established; nor can it be until, in the course of years, it can be shown that new cases are no longer arising.

A further role for the doctor as a human biologist is to insist that dust-suppression measures should not only be mechanically and physically effective but that the men who have to operate them should find them convenient and acceptable in use, and that they should find a policy of education come fully to appreciate their need. Sprays that are ill-adjusted may wet the men more than the coal and will be turned off. Excessive use of water in any method may cause unpleasant working conditions. Men are always unwilling to accept measures for their own safety that are inconvenient and require care and attention. Perhaps the most urgent needs to-day in the field of dust suppression are that more attention should be paid to the human factor, that in every piece of mining machinery automatic dust-suppression devices should be incorporated by the manufacturers, and that there should be fully trained dust-suppression officers in every pit.

There may always be certain mining methods in which the production of heavy dust clouds will be unavoidable—for instance, shot-firing. Under these circumstances it may be necessary for men to wear respirators. Unfortunately, no efficient respirator has yet been devised which men are willing to wear consistently. In the design of respirators filtration efficiency has been given priority over wearability, despite the obvious fact that an efficient mask in the pocket is of much less use than an inefficient mask on the face. In this field of investigation the biological approach is needed, giving first attention to the convenience of the man, if necessary at the expense of perfect filtration efficiency.

Increase in Certification Rates

The second important development since the publication of the first reports of the Medical Research Council has been an increase in the incidence of a certified disease, which, in point of time, followed the acceptance of the radiological condition of reticulation for purposes of compensation. Hart and Aslett considered the possible consequences of such a change in legislation, but concluded that a large increase in numbers of certified cases should not be anticipated, chiefly because respiratory disability, in the absence of which compensation is

not granted, was infrequent in cases of reticulation except in the later age groups.

Unfortunately, this forecast was not correct, as may be seen in Chart I, which shows the number of men certified as totally or partially disabled in each year from 1931 to 1946. After the introduction of the Coal Miners' Pneumoconiosis Order in 1943, applications to the Board rapidly increased. At first the Medical Boards were overwhelmed in South Wales, and a large waiting-list was built up. More doctors were appointed in 1944, and the number of men certified rose to over 5,000 in 1945, to fall again in 1946. Provisional figures for 1947 show a further fall to just under 3,000. It is to be noted that certifications have continued to rise in the other coalfields of Great Britain, and provisional figures for 1947 show a further rise to just under 1,000.

The mean rate of certification since 1942 has risen to four or five times the rate in that year. There are no precise figures available to show what proportion of this increase was caused by the inclusion of cases of reticulation, but Dr. N. Keating and Dr. J. C. McVittie, of the Cardiff and Swansea Silicosis Boards, estimate that of the men certified since July, 1943, approximately 50% have been cases of reticulation that would previously have been rejected. Thus, since only half of the increase can be accounted for on this basis, there must have been a considerable increase in the number of applicants to the Board with more advanced disease than reticulation. It is important to consider why this increase has occurred.

There is no doubt that men with quite advanced pneumoconiosis can continue to work for many years underground. At first they may have no symptoms. Later, with increasing symptoms, economic pressure and fear of unemployment may

CHART I.—Number of men certified by the Silicosis Medical Boards as partially and totally disabled by pneumoconiosis and silicosis in each year from 1931 to 1946. Above: South Wales. Below: Rest of Great Britain. The population at risk is about six times greater in the rest of Great Britain than in South Wales. The percentage of applicants rejected by the Medical Boards in each year in South Wales is also shown.

keep them at work. Any influence which will lead men to apply with greater readiness to the Silicosis Boards will therefore give rise to an apparent increase in the incidence of all stages of the disease as judged by certification rates. Two such influences have recently been of importance, at least in South Wales.

The first has been the operation of the Essential Works Order, under whose provisions during and since the war men could leave coal-mining on medical grounds only. In South Wales before the war there was little alternative employment for a coal-miner, but by 1942 war industries were in full operation, so that there was actually a labour shortage. Wages were high in these factories and conditions good. If after a day's toil at the coal-face a man comes home tired and dirty to find that his daughter, fresh from a day of light bench work, has earned more money than he has, he may begin to think of following her example. Many men found an application to the Silicosis Medical Boards a means of escape from mining to easier and more remunerative work. The second influence, in South Wales at least, has been increasing awareness among miners of the risk of pneumoconiosis. Miners are well-educated men, and in many a workman's club library the Medical Research Council's Reports on Chronic Pulmonary Disease Among Coal-miners are well thumbed and well understood. In every mining village in South Wales patients certified as suffering from silicosis can be seen pausing for breath on the hills. In a recent study undertaken by the Social Survey (1947) to investigate the problem of recruitment to coal-mining 68% of mining men in South Wales gave danger to health and dustiness as the chief objection to mining, whereas in other mining areas this objection was not raised by more than 40% of those questioned. The weight of these influences is shown by the large number of unsuccessful applications to the Boards. It might have been expected that the adoption of reticulation as a basis for compensation would have resulted in an abrupt fall in the percentage of cases rejected. In fact, as may be seen in Chart I.

no such fall occurred because of a rise in the number of applicants with insufficient disease for certification.

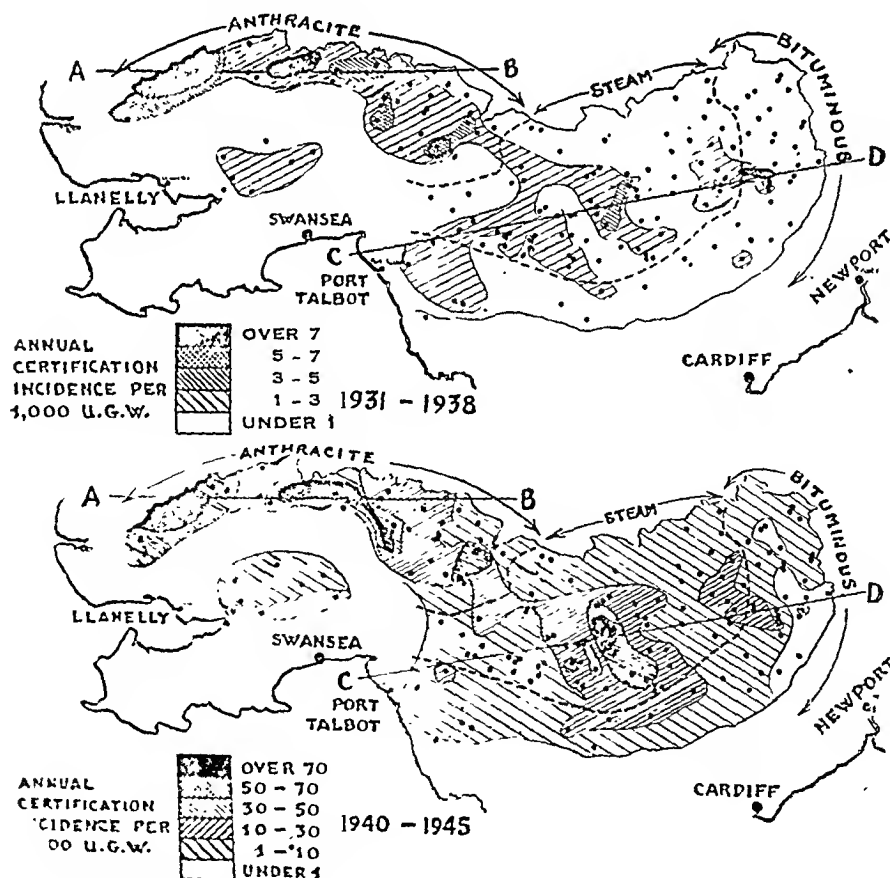

It also will be seen in Chart I that during the past five years there has been a slight but definite rise in the number of cases certified as totally disabled. These men have such severe symptoms that they would have applied to the Board regardless of any outside influence. This increase in numbers of advanced cases suggests that there has been a true increase in incidence recently.

Further evidence for such an increase may be derived from an analysis of the geographical distribution of certified cases which I have made with the help of my colleague, Mr. H. H. Watson, by calculating the annual certified incidence per 1,000 underground workers in all South Wales mines employing more than 100 men underground. These incidence rates were calculated for two periods, 1931-8 and 1940-5. The mines were then classified into groups showing, in the first period, annual rates per 1,000 of less than 1, 1-3, 3-5, 5-7, and over 7; and in the second period into groups showing annual rates per 1,000 of under 1, 1-10, 10-30, 30-50, 50-70, and over 70. When these rates are plotted on a map of the mines in the South Wales coalfield (see accompanying Maps) it is possible to draw "contour" lines enclosing those pits which fall within the same incidence groups. It is interesting to note that while pits with widely differing incidences may adjoin one another, areas of high incidence, in general, are surrounded in turn by areas of medium and low incidence. I cannot enter here into the complex factors which determine the disposition and shape of these contours, but will only state that the incidence of certifications is probably closely related to actual disease incidence. In the first period the groups of high-incidence mines in the anthracite area are clearly seen: there is a long irregular tongue of medium incidence extending into the steam-coal area, and there is another small but sharp peak of high incidence in the bituminous area. Elsewhere the annual rate is less than 1 per 1,000.

In the second period, in which the incidence levels at which contours have been drawn are ten times as great as those in the first period, the anthracite peaks remain, the bituminous peak is but a relatively low mound, but the striking change is the high peak that has developed in the steam-coal area, especially in the Rhondda Valley, which now rises to match the western heights. Only a small area in Monmouthshire has retained an annual incidence of less than 1 per 1,000.

The outstanding increase of incidence in East Glamorgan is brought out again in Table III, in which the pits have been grouped geographically into four main areas and the ratio between the average incidence in the two periods throughout these areas is shown. In the anthracite area, in West Glamorgan and in Monmouthshire, the average increase of incidence lies between sixfold and sevenfold. In East Glamorgan, however, the increase is nearly three times as great. A fallacy in these ratios might be caused by a disproportionate decrease in underground man-power in this area, but the percentage decreases in underground man-power (also shown in Table III) are similar in all the areas.

We must also consider the possibility that the high ratio in East Glamorgan might be due not to a real increase in incidence but rather to a later development of awareness of the disease in this area. In this case the disproportionate increase in certifications might be due to a flood of applicants whose disease originated in the earlier period but who had for some reason delayed applying to the Board until the later period. If this

Maps of the South Wales Coalfield showing the incidence of certified silicosis and pneumoconiosis in 1931-8 and 1940-5 in all mines normally employing more than 100 underground workers. The small black circles each represent a single mine. "Contours" have been drawn enclosing mines at which the incidence of certified disease per 1,000 underground workers per annum falls into the same group. These incidence groups are shown in the Map. U.G.W. Underground workers.

were so we should find that the cases coming from the high-incidence steam-coal pits were older men than those coming from the other pits. Figures for the age distribution of certified cases are available for only ten pits in the anthracite area and six high-incidence pits in the East Glamorgan steam-coal area, but these should be representative figures, and it will be seen from Chart II, which shows the age distribution of certified

CHART II.—Age distribution of all cases certified with silicosis and pneumoconiosis between 1940 and 1947 at ten anthracite mines and six high-incidence steam-coal mines in East Glamorgan. The height of the vertical columns represents the percentages of all cases falling into 10-year age groups.

cases during the second period from these two areas, that on the whole the East Glamorgan cases are the younger men. This finding is inconsistent with delayed awareness of disease in this area and is consistent with a real increase in incidence.

To sum up, we may conclude from these certification figures that the change in legislation in 1943 and the tendency for men to seek employment outside coal-mining may account for the general increase in the certification rate during the past six years, but that some additional factor must have operated in the East Glamorgan steam-coal pits, especially in the Rhondda Valley, to produce a real increase in disease incidence.

What, then, may this factor have been? The rank-of-coal hypothesis would demand that dust concentrations must have been much higher in steam-coal pits than in anthracite pits in order to give as high an incidence. There must then have been some relatively recent rise in dust concentrations in the East

Glamorgan steam-coal pits to account for the big increase in certified incidence there. It was in these pits that intensive mechanized mining was first adopted in South Wales, and there is general agreement among mining men that these methods gave rise to an enormous increase in dustiness. These mechanical methods of mining were mostly introduced in the early nineteen-thirties and would have been expected to produce a rise in certification rate beginning seven to ten years later, which in fact we find; for this is the minimum period necessary for the development of a certifiable degree of pneumoconiosis in most cases (Hart and Aslett, 1942).

Unfortunately, quantitative information concerning dust concentrations in South Wales pits before the institution of dust suppression is scanty. However, Briscoe *et al.* (1943) give figures for the mass concentration of air-borne dust in the pits at which colliers had been examined by Hart and Aslett (1942). Unfortunately, they did not include any high-incidence steam-coal pits. However, rather scanty figures are given for mass concentrations of air-borne dust at coal-faces in some of these pits before dust suppression in the 15th Report of the Coal Dust Research Committee of the Monmouthshire and South Wales Coal Owners' Association. In Chart III the annual certified incidence at various pits between 1940 and 1945 per 1,000 underground workers is plotted against the total mass concentrations of air-borne dust derived from these two sources. The figures

CHART III.—Relationship between annual certified incidence per 1,000 underground workers (horizontal axis) and air-borne dust concentrations expressed as mg./cu.m. (vertical axis) at seven South Wales coal-mines. Circles representing mines for which figures are available from both sources are joined by a dotted line.

for the pits surveyed by both investigators are joined by a dotted line in the chart. There is a fairly direct relationship between certified incidence and total mass concentration of dust, but there appears to be a systematic shift in the dust levels between the two sets of estimations which may be due to the difference in the methods of sampling employed. However, if allowance may be made for this shift by bringing the figures from the pits surveyed by both investigators to the same level, it appears that dust concentrations in anthracite and steam-coal pits of equivalent certified incidence were similar and not much greater in the steam-coal pits, as would have been demanded by the rank-of-coal hypothesis, upon which some doubt is thus thrown.

Too much weight must not be placed upon this rather unsatisfactory evidence, and it must be admitted that there are a few

figures recorded for dust concentrations under exceptional circumstances in steam-coal pits (for instance, at loading points) which are higher than any figures recorded by the Medical Research Council's investigators in anthracite pits. But it is fair to say that at present there is no good evidence that conflicts with the hypothesis that differences in the concentrations of air-borne dusts rather than differences in the constitution of the dusts chiefly account for the differing incidence of the disease among the coal-miners of South Wales.

This does not mean that qualitative differences in the dust clouds are of no importance. That they are important is indicated by Hart and Aslett's demonstration that rock workers have a greater tendency than colliers to develop radiological abnormalities. Since, however, there is in South Wales at least a hundredfold variation in the concentration of air-borne dust at the coal-face from mine to mine, while the variation in silica content, for instance, is less than tenfold, any effect of the qualitative differences in the dusts is concealed by the far greater quantitative differences.

I suggest, therefore, that the earlier development of a high incidence of pneumoconiosis in anthracite mines was due to high dust concentrations resulting mainly from poor ventilation, especially during the nineteen-twenties; and that its late development in steam-coal mines was due to high dust concentrations resulting from the introduction of intensive mechanical methods of mining in the dusty coal seams of East Glamorgan during the next decade.

This problem of the differing and changing incidence of the disease in South Wales pits is one to which we are devoting considerable attention in the Pneumoconiosis Research Unit. We have started a programme of radiological surveys at selected pits and we shall attempt to correlate our findings with the results of dust surveys. For this latter purpose it is essential that we should have some rapid and simple method of assessing dust concentrations. Hitherto all methods in common use either have been laborious or have involved the use of cumbersome equipment. Mr. H. H. Watson has devised a simple method (Watson and Hounam, 1948) by which air is drawn through a piece of filter-paper by a simple hand-pump and the resultant stain of coal dust is rapidly assessed by a photo-electric densitometer. Using this method, we have already carried out many surveys. Perhaps the most important preliminary result of these surveys has been the demonstration that there are tremendous variations in dust concentrations both from minute to minute and from day to day at the same face with unchanged working conditions. There is thus great difficulty both in giving representative single figures for air-borne dust concentrations and in assessing dust conditions by means of a brief visit from a mines inspector or a dust control officer. Some automatic method of continuous recording of dust concentrations is needed, and our physicists are now turning their attention to the development of such a method.

Pneumoconiosis in England and Scotland

Finally, we must consider briefly the incidence of pneumoconiosis of coal-miners in Great Britain outside South Wales. The total number of certified cases in South Wales is approximately seven times the number in the rest of the country (see Chart I). Since there are nearly six times as many coal-miners in the rest of the country, the incidence of certified disease is nearly 40 times greater in South Wales. The important question is whether this difference in incidence is genuine or whether awareness of the disease has not yet spread to the whole country so that the rising figures of incidence for Great Britain as a whole forbode a disastrous situation arising there during the next few years as it has during the last few years in South Wales. Intensive mechanical methods of mining have been introduced to a greater extent in the rest of the country than in South Wales, and it is not unreasonable to fear that we may see these methods being followed by the same consequences as they have in East Glamorgan. I believe such a pessimistic forecast may be unjustified for three reasons:

1. In Table III it may be seen that the ratio of certified disease in 1940-5 relative to that in 1931-8 for pits in South Wales is much closer to the general ratio for South Wales than that for East Glamorgan, where there has been a large increase in incidence. This might be interpreted as suggesting that the rising figures outside South Wales are more likely attributable to social and economic factors than to a real increase in disease incidence. A further regional analysis of the ratio shows that its slightly higher value than that for South Wales excluding East Glamorgan is due chiefly to a high ratio in Scotland, Durham, and Denbigh, which may suggest a more recent increase in incidence in these areas.

2. During the past three years 14 mass miniature radiography surveys have been carried out by local authorities at collieries in England. In these surveys the non-attendance rate has been high, averaging 50%, so that great caution must be used in deriving conclusions from their findings. So far as they go, however, they do not suggest a serious position, the incidence of all abnormalities described as suspected pneumoconiosis being only 1.7% of all employees examined. This compares favourably with Hart and Aslett's findings among coal-miners in the lowest-incidence mines in South Wales.

3. There is the obvious fact that if overall mass concentration is the most important factor in the causation of the disease then no really dusty pit can be a low-incidence pit. The low incidence outside South Wales should therefore mean that there are no really dusty pits in the other coal-fields in Great Britain. Statements to the contrary, however, have been made (Graham and Jones, 1947), and we felt that we should investigate this point. With the help of the Mines Inspectorate we have been introduced to several reputedly dusty pits in North Staffordshire, Northumberland, and Cumberland which have a low incidence of certified disease. Mr. Watson has made estimations of the dustiness at coal-faces in these pits, and to our satisfaction he has found so far that the air-borne dust concentrations, although they may reach levels which we find in high-incidence pits in South Wales after dust suppression, do not reach the levels which existed under the former uncontrolled conditions. Our explorations as yet are only preliminary, but they do not lend support to the idea that many pits in Great Britain are sufficiently dusty to give rise to an incidence of pneumoconiosis such as has prevailed in the pits of South Wales.

It is with considerable hesitation that I suggest that there is no reason to fear the development of pneumoconiosis in Great Britain as a whole on a scale of severity such as that to which South Wales has been subject, for I am aware that doctors have in the past been guilty of disastrously mistaken complacency. However, we shall not remain content with this fragmentary evidence, and shall seek further sound information. Meanwhile the results of fuller inquiries may be awaited with reasoned confidence.

[The second lecture, with a list of references, will appear in the next issue.]

Dr. Conrad Berens, of New York, was elected president of the Pan-American Association of Ophthalmology at the Third Pan-American Congress of Ophthalmology held in Havana, Cuba, Jan. 4-10. The next Congress will be held in Mexico City, 1952. The Congress adopted statutes and by-laws establishing the Pan-American Association of Ophthalmology as a continuing organization with the objects of fostering the progress of ophthalmology, establishing contacts among ophthalmologists of the Western Hemisphere, and promoting measures to conserve eyes and prevent blindness among the peoples of the hemisphere. To achieve these aims permanent committees were established to deal with the following matters: research, glaucoma, trachoma, light and optics, contact-lens centres, orthoptics, prevention of blindness, neuro-ophthalmology, legal and industrial ophthalmology, standardization of ophthalmic hospitals and clinics, inter-American medical relationships, establishment and guidance of ophthalmological societies, and scientific cinematography. A board of censors was formed to supervise the relations of Association members to the lay press. According to the resolution adopted at Havana, the representatives of the Association's press relations committee may approve publication of articles in the lay press concerning members.

DEFICIENCY SCROTAL DERMATITIS IN P.O.W.s IN THE FAR EAST

BY

A. W. FRANKLAND, M.A., B.M., B.Ch.

(From the Wright-Fleming Institute of Microbiology, St. Mary's Hospital, London)

The condition here called deficiency scrotal dermatitis has not, so far as I am aware, yet received an adequate clinical description. Its prevalence among Allied prisoners of war in the Far East presented unrivalled opportunities for clinical observation, and it seems desirable to record a study of 551 cases. It is to be regretted that observations on the specific nature of the syndrome were precluded by the circumstances of the situation. Scrotitis is an ugly word, and "the urogenital syndrome," a term used by Mitra (1943), seems an inadequate description of many of the cases that were seen. For these reasons the term "deficiency scrotal dermatitis" has been adopted for the condition to be described.

Scrotal dermatitis first appeared among prisoners of war on Singapore Island in May, 1942, three months after their capture. During the six months from July 1 to Dec. 31, 1942, 1,371 cases were admitted to the skin ward at the main hospital for British personnel. Of these, 551 were primarily admitted for scrotal dermatitis. It should, however, be stated that many medical officers ran their own camp reception stations, so that not all cases were admitted to the main hospital. Pavillard (1946), writing of a camp in Singapore Town where 650 men remained for six months before going to Siam, states that "practically the whole camp suffered from scrotal dermatitis." This would not be an overstatement for most of the camps on Singapore Island.

After leaving the main camp at Changi in November, 1943, no cases of scrotal dermatitis occurred in any personnel under my care, though in Changi in 1944 there was a severe outbreak of new cases. Vegetables were difficult to get, and Clarke (1946) concluded that "scrotal dermatitis with its concurrent lesions was due to a deficiency of greens." Scrotal dermatitis was, however, still present in some prisoners of war on Singapore Island one month after their release (Mitchell and Black, 1946).

Symptoms and Signs

The first symptom noticed was an irritation of the scrotum, always worse at night and often becoming so severe as to make sleep impossible. In the daytime men were often seen subconsciously scratching the affected part, but during work or if the patient got hot the irritation would become temporarily worse, and was unrelieved by scratching. In its mildest form the scrotal dermatitis would last for only a few days and then would relapse and last days or weeks. Heavy work, heat, and illness were the chief precipitating causes of the onset or a relapse. It is important to recognize the mild early stage because the condition is not simulated by a tinea or an eczema due to other causes. If untreated it developed in a number of different ways, making it possible to classify the more advanced cases. It should be understood, however, that the distinction between the different forms was not always clear.

1. Mild Acute Dry.—This form was present in almost all prisoners of war in Malaya six months after captivity. The front of the scrotum became red, with the medium raphe showing as a smooth white line dividing the slightly raised and thickened erythematous surface. This condition might persist for a few days or weeks. Finally, with or even without treat-

ment, a fine desquamation would leave an apparently normal-looking scrotum. In the coloured races the erythema could not be recognized, though the stage of desquamation could easily be seen.

2. Severe Chronic Dry.—The front of the scrotum looked a bright red. Where the scrotal skin came in contact with the inner sides of the leg a few erythematous punctate areas appeared which later joined together to form a continuous blush. In more severe cases the skin round the anal margin and interanal cleft became red and painful, and fissures were often present. The under surface of the skin of the penis as it rested on the front of the scrotum commonly became red and irritable. The condition seemed to spread around the corona and on to the glans penis. In the uncircumcised, cracks appeared at the free margin of the prepuce, so that balanitis and phimosis often made circumcision necessary.

3. Chronic Wet.—This was the condition for which patients were admitted to hospital, though ambulatory treatment was of necessity often employed. The whole surface of the scrotum became wet and the inner sides of the legs were similarly involved. In the mild forms the scrotum might become dry again in a few days, in which case desquamation would occur, leaving a smooth shiny scrotal skin. If the moist state continued for over a week before the scrotum became dry a crepitant sensation, like egg-shells cracking under the skin, was observed. When the wet condition persisted the skin became macerated and fetid, and the cracks in the skin around the anus, cruro-scrotal junction, and preputial margin spread and became more painful. Without treatment the area of weeping and of infection increased until the condition developed to type 4.

4. Ulcerated and Oedematous.—The scrotum might now become as big as a football. Walking was almost impossible, as fluid and pus oozed from the fetid area. The scrotal skin was extremely painful from ulceration. In some cases flies had laid their eggs in the scrotal ulceration, and the maggots as they moved about caused an extremely painful contraction of the cremaster muscle. Serum exuding from the scrotum was thus an ideal culture medium for *Corynebacterium diphtheriae*. In the worst cases a spreading gangrene from the scrotum to the legs and lower abdominal wall, with marked generalized toxic symptoms with or without diphtheritic infection elsewhere, terminated in death.

Associated Vitamin-deficiency Diseases

A detailed analysis of the other stigmata of vitamin-deficiency disorder occurring in patients with scrotal dermatitis was confiscated by the Japanese. It is, however, possible to give an approximate picture of the associated syndromes.

Oral Lesions.—The commonest lesions found associated with deficiency scrotal dermatitis were those of angular stomatitis, sore lips, and sore tongue. Stannus (1912) originally used the term "angular stomatitis" to describe a soreness at the commissures of the lips, with redness and desquamation along the line of closure. The angles of the lips became fissured and secondary infection was common. This condition must be distinguished from a cheilosis, which is an affection of the vermillion of the lips. The tongue lesions were so common that few subjects of established scrotal dermatitis had a normal tongue. In its mildest form the tip of the tongue only was involved. The tip looked tender, but only hot fluids and highly seasoned food actually caused pain. Later the whole surface of the tongue became either bright red or, more commonly, magenta-coloured. The thickened epithelium would flake off in patches, giving the so-called "geographical tongue." On the other hand, in a minority of cases the tongue was remarkably smooth and glazed in appearance. An infrequent finding was a bright redness of the soft palate and anterior pillars of the fauces. These cases had often been referred to the ear, nose, and throat department with the diagnosis of "pharyngitis." They were quickly cured by adequate doses of "marmite."

Skin Lesions.—Mild superficial desquamation on the nasolabial folds and on the skin adjacent to the pinna was a very common finding. A rather similar condition of the canthi, described by other observers, was very rarely seen. Some

patients who had been severely ill developed a fine dry scaling mosaic pattern of the skin of the body which did not quickly respond to any form of treatment. In some of the accounts of syndromes related to deficiency of the vitamin-B complex scrotal dermatitis, if mentioned at all, has been included in the term "pellagra." This is unfortunate, since the aetiology of the two diseases is not the same. Of the 551 cases under review only two had associated pellagroid skin changes. These consisted of a pigmentation and roughening in those areas of the skin most exposed to the sun. If thus exposed for any length of time the pigmented areas became painful and a patchy desquamation spread from the centre towards the periphery of the lesion. Five cases showed a follicular hyperkeratosis. This was most pronounced on the forearms just below the elbows and on the outside and back of the legs. The rough porcupine condition of the skin could be felt better than seen. It was cured by giving adequate doses of vitamin A in the form of red palm oil.

Painful or Burning Feet.—Cruckshank (1946), in a review of 500 cases of painful feet under his care while a prisoner of war, states that 30% suffered from scrotal dermatitis. Cases were admitted to the skin ward primarily for skin complaints only. Of the 551 patients under review six complained of painful feet. Nicotinic acid or its amide cured four and relieved the other two.

Ocular Manifestations.—These were of two types: the more common one, for lack of literature, was called granular cornea; the other, retrobulbar neuritis. Granular cornea, retrobulbar neuritis, and scrotal dermatitis were in many cases present together, but the three diseases seem to bear little relation to one another with respect to date of onset and peak number of cases seen in any one month. In those suffering from granular cornea or keratitis the presenting symptoms were photophobia, itching and burning of the eyes, and a sensation of eye-strain. The eyelids were kept half shut, but beyond a general conjunctival injection, and without using slit-lamp investigation, no gross changes could be seen. If obvious corneal ulceration occurred the usual curative methods were found to heal extremely slowly. Permanent scarring did occur in some cases. The retrobulbar neuritis was in many cases more difficult to diagnose because the symptoms often arose without evidence of structural change. Although the maximal disability sometimes appeared suddenly, the symptoms generally took weeks or months to develop fully. Blurred vision or inability to recognize faces was the usual complaint. Sometimes patients suddenly found that they could not read, while others were unaware of any disability when a central scotoma was found on examination.

Illustrative Case.—A patient was admitted in November, 1942, complaining of a weeping scrotal dermatitis and blurred vision. At the end of a fortnight's treatment the scrotal condition had healed but the sight was becoming worse. One morning he failed to see his bed, walked into it and injured himself. Three months later, when vision had improved to counting fingers, there were still no abnormal disk changes.

Smith (1946) states that in the civilian internment camp, Hong Kong, where similar dietary conditions prevailed, of the 370 cases of retrobulbar neuropathy 143 (38.7%) had suffered from the orogenital syndrome. Ridley (1945) found that, although 48 out of 100 cases of amblyopia in former prisoners of war showed definite pathological pallor of the temporal halves of the disks, the appearance of the disks was sometimes normal even in severe and prolonged cases. Similar findings were noted a year before release in 46 patients who complained of blurred vision. Only one of these showed marked optic atrophy in both eyes; 16 showed slight temporal pallor in one or both eyes; and in the remainder the fundi appeared normal. Night-blindness was never complained of, though it is said to have occurred in other camps in the Far East. It was found that men with eye symptoms asked to go on the unpopular night working parties if there was a chance of getting off the following day's work in the glaring sun, probably because of the associated photophobia or a more rare mydriasis.

Nerve Manifestations.—Patients suffering from painful feet, retrobulbar neuritis, peripheral neuritis, or nerve-deafness were admitted to the skin ward for scrotal dermatitis if the latter disease was considered the more serious one. No case admitted primarily for scrotal dermatitis developed symptoms of a

pyramidal-tract disorder with signs of spastic paraplegia, although in an account of this syndrome by Graves (1947) two of the four fatal cases showed evidence of scrotal dermatitis.

Differential Diagnosis

So far as is known no other disease simulates the mild form of deficiency scrotal dermatitis already described, though by the time the condition becomes chronic, or more severe, it is possible that it will not be recognized as a deficiency disorder. Chemical dermatitis was produced in some of our mild cases by the application of various medicaments, particularly a paste the base of which was an antimalarial ointment containing citronella. Eventually its use had to be prohibited. Dhobie itch, prickly heat, and intertrigo are commonly seen in hot countries, especially under Service conditions. Tinea cruris (dhobie itch) can usually be recognized by the sharply defined growing margin of the ringworm on the legs.

Many of the cases that had begun as a deficiency scrotal dermatitis developed a superadded ringworm infection, and this was in fact presumed to have occurred in cases refractory to the usually effective treatment. Prickly heat rarely affects the crutch only, and an intertrigo, when it occurs in that part, is not quickly cured by adequate amounts of vitamin B. Eczema of the perianal margin is not infrequently seen in any dermatological clinic. This condition tends to start around the perianal margins and not to spread there from the scrotum. Furthermore, the skin later may become lichenified—a condition which apparently does not occur with true deficiency scrotal dermatitis. A seborrhoeic or exogenous dermatitis involving the scrotum might well be mistaken for the type of scrotal dermatitis seen among prisoners of war, especially as there were other seborrhoea-like lesions on the body.

As already mentioned, as soon as the scrotal condition became moist, secondary infection with *C. diphtheriae* was apt to occur. A routine culture in all cases when this was possible showed that some patients with weeping scrotal dermatitis were chronic diphtheritic carriers. More commonly, however, the clinical condition resembled cutaneous diphtheria elsewhere, except that once infected the scrotal skin was liable to become extremely thickened from oedema. This oedema differed from the gross oedema seen in some of the cases of oedematous beriberi in that the skin was weeping and ulcerated to start with and the oedema followed. In a few cases of oedematous beriberi the skin ruptured and became infected later. In some cases the scrotal condition had not reached the weeping stage but the men reported sick with a sore mouth and a whitish diphtheritic membrane spreading over and completely occluding the red lips. These men generally had a diphtheritic angular stomatitis and cheilosis, and a redness or crusting or frankly diphtheritic membrane inside the nose—a sign that always had to be looked for, because there was rarely any complaint about the nose.

Treatment

Curative; Specific.—It was soon found that marmite or "vegemite" given in 1-oz. (28-g.) doses daily for eight days cured mild cases of scrotal dermatitis. In the mild diphtheritic type the scrotal irritation had usually disappeared completely by the second night. A fine desquamation would follow, and then, if the condition had been present for some time, the scrotal skin lost its rugae and became smooth in appearance. A longer period of treatment was necessary for the more severe cases, some of the patients having to remain in hospital for over two months. This chronic state could not be accounted for by infection. With the low vitamin-B content of the diet relapses were apt to occur.

Non-specific.—Local treatment was limited to the availability of any drugs or dressings. Many men, by keeping themselves well washed and dusted with powder, were able to postpone the onset of the weeping condition. Calamine lotion when available had much the same effect as a dusting powder. In its dry or early moist stage serotal dermatitis could be prevented from becoming worse, and in some cases was almost cured, simply by resting and keeping cool. This, of course, was often impossible. When the weeping variety had become established the ideal treatment was rest in bed—again impossible to obtain. Of the many local applications tried wet dressings of normal saline were probably the most effective, and had the added advantage that when all other drugs had been finished salt and water were always available, though the former was used at the expense of the already low salt ration in the diet. Hypertonic saline was used, but was found to be too painful, and it had no advantage over normal saline. Very dilute solutions of eusol, boric acid, mercuric perchloride, mercuric bimodide, lead lotion, silver nitrate, and mercurochrome were also used. A dilute solution of eusol was perhaps the best local application, but some patients became eusol-sensitive after using this form of treatment for a number of days. When the local condition had healed completely patients were allowed out of bed and only a dusting powder was applied; but relapses were liable to occur if the wet dressing was not kept on for the requisite time, which varied from two to three days to as long as two months.

Prophylactic.—Attempts to supplement the meagre diet with sources of the vitamin B complex were not very successful. Yeast brews apparently had no effect on serotal dermatitis, and rice polishings in doses of 1 oz. (28 g.) a day made no appreciable difference. Extracts of macerated green leaves or grass, if in a concentrated form, were effective prophylactically and therapeutically in some cases.

Discussion

Stannus (1944) believes that the endothelium of the capillary system is the first tissue to suffer in a riboflavin deficiency, resulting in a loss of tone and dilatation. Normal cellular metabolism is upset and the tissue functions are disturbed—what he terms a "capillary dysergia." He considers that the skin lesions of an ariboflavinosis occur where the skin is thin or highly specialized and at the mucocutaneous junctions of body orifices. He does not seem to have stressed that the lips, nares, prepuce, anus, scrotum, etc., are particularly liable to constant mild trauma. In serotal dermatitis it may well be that there is the added factor of mild trauma in association with excess heat. It is known that warmth and exercise of the body may produce urticaria or eczema of the skin in a sensitive allergic patient. It has been suggested that when cellular nutrition is interfered with in these patients, although the various mechanisms are not fully understood, there is a release of histamine or H-substance into the tissue space. Arguing on a similar basis, it may be possible that, in a riboflavin deficiency, with the interference of cellular metabolism there is a production of histamine or H-substance. If this is so, here is an explanation of the similarity between the skin disorders of an eczematoid type seen in allergic conditions and some of the skin changes seen in hyporiboflavinosis, especially those round the mucocutaneous junctions of the body orifices.

In many written reports of the signs of vitamin-B deficiency serotal dermatitis was not mentioned, though it may well be that it was not always looked for. Many observers had, however, noticed its appearance. Stannus (1912, 1913) described its occurrence. Purcell (1942), in reporting six cases of nutritional glossitis, noticed four cases of itchy or scaling scrotal skins. These were not benefited by

100 mg. of nicotinic acid, but cleared up on 5 mg. of riboflavin daily. Landor (1939) had previously noted ten cases with similar results. Sydenstricker (1941), writing on the B-group avitaminosis, remarks that pruritus of the vulva or scrotum may be present. Sebrell and Butler (1938) maintained a group of patients on a diet poor in riboflavin content. In their experiment the first sign of vitamin lack to appear was one of cheilosis. They then described the various other manifestations generally attributed to a riboflavin deficiency. They state that only rarely was there a dry brown itching dermatitis of the hands and scrotum. As they had already mentioned that a generalized extensive seborrhoeic dermatitis might be a manifestation of riboflavin deficiency, the serotal condition was not particularly stressed. Fitzgerald Moore (1937), who was interested in the eye changes in vitamin-B deficiency, remarked that, among other symptoms, there were associated active signs or a past history of a scaly itchy scrotum.

Mitra, writing on what he termed the orogenital syndrome in avitaminosis, noticed, as have other observers, that nicotinic acid may make the condition worse, while on riboflavin all cases were cured or showed much improvement. It is interesting that Thomson (1944), in a description of beriberi among naval ratings in Malaya, described two cases of eczema of the scrotum without demonstrable signs of any other deficiency. Landor in 1939 described eczema of the scrotum and stomatitis occurring in Singapore Gaol which was not cured by nicotinic acid but responded to yeast or marmite. Owing to lack of literature it was quite a time before some of the doctors in the prison camp who had been working in Malaya before the war recognized serotal dermatitis as a disease with which they were already familiar in the local gaols.

Serotal Dermatitis as a Manifestation of Riboflavin Deficiency

It may be argued that the foregoing account of serotal dermatitis adds little to our knowledge of a vitamin-deficiency disease or even that it does not prove the disease described to be due to vitamin lack. It has already been explained that the circumstances of the situation precluded a scientific study of the specific nature of serotal dermatitis. All that has been attempted is a description of an almost universal complaint suffered by prisoners of war while living under conditions in which diseases due to vitamin-B deficiency were certain to occur. It is only by recording other workers' observations on serotal dermatitis that an assessment can be made of the aetiology of the disease.

Purcell, Landor, Sebrell and Butler, and Mitra have all produced evidence that serotal dermatitis occurs in patients on a low riboflavin diet and that the condition can be cured by riboflavin. Burgess (1946) has shown from the detailed analysis of the diet at Changi camp that serotal dermatitis occurred inversely with the riboflavin intake, though, at Hong Kong, Smith's graph of the riboflavin content of the diet and the incidence of new cases of the orogenital syndrome show no very close correlation.

It was unfortunate that pure riboflavin was not available at the camp, and that of the three preparations which were effective for the cure of serotal dermatitis the riboflavin content of one of them—namely, green-leaf extract—was unknown. However, the following figures supplied by the makers represent the range of riboflavin content for marmite and vegemite. Marmite contains 0.055 to 0.067 mg. per g. and vegemite 0.045 to 0.06 mg. per g., or a probable minimal value of 1.5 mg. per oz. Williams and others (1943) suggest that 0.5 mg. per 1,000 calories is an adequate intake of riboflavin, so it is not unreasonable to suppose that the quantity of riboflavin contained in 1 oz. of marmite or vegemite would, together with the riboflavin

of the diet, be adequate to produce signs of cure in a case of riboflavin deficiency. It must be remembered that riboflavin, nicotinic acid, pyridoxin, pantothenic acid, choline, and folic acid are some of the known factors present in any extract such as marmite which, together or alone, may be responsible for any observed therapeutic effects.

Summary

Scrotal dermatitis was a common complaint among prisoners of war in Malaya six months after captivity. It was noted that no cases of scrotal dermatitis occurred when the riboflavin content of the diet was maintained at a sufficiently high level.

A description of the different types of deficiency scrotal dermatitis seen is given, together with the associated vitamin-deficiency diseases.

Previous workers who have described the complaint have suggested that it is due to a deficiency of the riboflavin content of the diet. The curative effect of marmite (or vegemite) was found to be specific in mild uncomplicated cases.

I wish to thank Dr. John Freeman and Dr. H. Scarborough for their advice and encouragement.

Addendum Since writing the above description of deficiency scrotal dermatitis this condition has also been commented on by Sefton, L. (*Brit. J. Derm. Syph.*, 1947, 59, 85).

STREPTOMYCIN IN BUBONIC PLAGUE

BY

Ch. HADDAD, M.D., D.T.M.

AND

A. VALERO, M.B., Ch.B.

(From the Department of Health, Palestine)

In 1947 bubonic plague broke out suddenly in Haifa and later spread to Affula, a village 30 km. to the south-east. The outbreak was suppressed quickly by the extensive use of D.D.T., but it gave us the opportunity of observing the effect of streptomycin in three severe cases. As little experience has been gained in the use of this antibiotic against plague (Herbert, 1947; Karamchandi and Rao, 1948) a brief report on our observations may be justified in spite of the small number of cases presented.

The outbreak started explosively. The first case, the only fatal one, was admitted to hospital on June 23, 1947. Within the next 13 days 13 more cases, all from Haifa, were admitted, and there were 3 from Affula on July 19.

Sulphonamides, especially sulphadiazine, which is now considered the most potent sulpha compound against plague (Platzner, 1946; Huangl and Chu, 1946), were administered as a routine to all cases. Where possible the initial dose was 2 g., given orally, followed by 1 g. every four hours during the acute stage. Later smaller

quantities were given until the bubo healed. Results were favourable on the whole, but the condition of three patients, admitted when very seriously ill, deteriorated rapidly in spite of treatment. It was decided, therefore, to administer streptomycin. The results in all three cases were remarkably good.

Case Records

Case 1.—A male Arab aged 20 was admitted to hospital July, 1947, with the history that three days previously he had a severe rigor, a rise of temperature up to 39° C., and intense headache. On the following day, on discovering painful lymphadenitis in the right groin, his physician placed him on 400,000 units of penicillin daily. In spite of this his condition deteriorated and severe continuous vomiting started. The day before admission he became delirious.

On admission his pulse was 124, respirations 26, at temperature 40° C.; he was delirious and was vomiting. His face was haggard, the conjunctivae injected, the tongue dry and heavily coated. In the right inguinal region there was a tender solitary lymph gland the size of an almond, but the skin over it was not inflamed. Bubo puncture fluid was positive for *Pasteurella pestis*.

The patient was given a course of "soludagenan" (solute sulphapyridine) 1 g. intravenously every four hours. Nothing could be given by mouth on account of the vomiting, therefore glucose and normal saline were also administered intravenously.

On the same evening his general condition deteriorated and streptomycin 200 mg. was administered every three hours. The following morning the temperature dropped to 38° C. and in the evening it was normal. The patient, though still vomiting occasionally, was so much better that he was able to sit up in bed. Streptomycin was therefore discontinued on July 9. The temperature rose 24 hours later, a further 2 g. was given. From this stage recovery was uneventful. The bubo resolved and the patient was discharged on July 16.

Case 2.—A male Arab 8½ years old became ill on June 28, 1947, with a sudden and severe rigor, fever, vomiting, and headache. On June 29 he developed a painful swelling in the left groin, for which he received 1 g. of sulphathiazole thrice daily for 6 days. As there was no clinical improvement he was referred to hospital.

On admission on July 4 his temperature was 39.5° C. at pulse 130; his face was congested, the eyes were bloodshot and breathing was rapid and shallow. He was conscious but apathetic, and vomited repeatedly. The left inguinal gland was enlarged, tender, and inflamed. Bubo puncture fluid was found positive on direct smear and culture. Sulphadiazine 4 g. daily was prescribed.

The day after admission his condition became worse. The pulse was thready and vomiting continued, and he was incontinent of urine. On July 6 his condition deteriorated further, his temperature was 40° C. and delirium had set in. Streptomycin 200 mg. every three hours was therefore started at 8 a.m. By 4 p.m. the same day the temperature had fallen to 37.5° C. and the vomiting had ceased. Improvement was maintained during the next three days, during which the patient fed and took an interest in his surroundings. On July 10 his temperature rose again to 38° C. and an intermittent fever was maintained until July 14, when fluctuations became evident in the bubo, which was then incised. After that recovery was uneventful and the patient was discharged on July 26. Streptomycin had been discontinued on July 17.

Case 3.—A male Jew aged 35 was admitted to hospital on July 19, 1947, on the fourth day of his illness, which had started with a rigor followed by fever and vomiting. A painful swelling appeared in the left groin on the second day of the disease. The patient had been given sulphathiazole and penicillin for two days without effect.

On admission his temperature was 39.5° C., pulse 120, at respirations 24. The patient looked very ill. His face was congested, his tongue was heavily coated, and he complained of a very severe headache. In the left inguinal region there was a large hard swelling which was inflamed and tender. *P. pestis* was cultured from the bubo puncture. The patient was given sodium sulphathiazole 1 g. every four hours intravenously.

Two days after admission his condition grew worse: consciousness was clouded, the pulse 130, and respirations rapid and shallow. The bubo was larger, and inflammatory oedema extended from the middle of the thigh to the umbilicus. He was given 300 mg. of streptomycin every three hours, but hours later his condition was still serious. Although his temperature had dropped to 38° C. his pulse became thready, finger-tips bluish, and he was dyspnoeic. On July 23 there was a marked general improvement. The patient felt much better, his pulse rate was 92, he was no longer dyspnoeic, and was on the way to recovery. Streptomycin was continued till July 27. The bubo was still painful, but the abdominal oedema had subsided. On August 16 fluctuations became frequent and a thick purulent discharge was evacuated. The healing of the wound was delayed until Sept. 9, but the patient felt very well until his discharge.

Summary

Streptomycin treatment of three very severe cases of plague responding to sulphonamides resulted in speedy recovery. A fourth severe case was not treated with streptomycin, and a patient died on the eighth day of his illness.

Whereas the effect of streptomycin on the general condition of the patients was remarkably good, the buboes appeared to be uninfluenced if treated late. This was true also in respect of the sulphonamides, and in most cases incision and drainage were necessary to bring about resolution.

SOLITARY MYELOMA OF THE MANDIBLE

BY

RICHARD SPITZER, D.M.D.

AND

L. WOODHOUSE PRICE, M.A., M.D.

Pathologist to the West End Hospital for Nervous Diseases

The myeloma, or plasmacytoma, is a tumour of plasma cells which usually produces multiple lesions, causing a systemic affection of the body. As distinct from generalized myelomatosis of bone, the solitary myeloma is not uncommon in the nasopharynx and in single bones such as a vertebra or clavicle. Very few references, however, can be found on lesions of the jaw affected by the solitary type of myeloma. William Tennent (1945) in a survey of 49 cases does not mention a single tumour of the mandible. No reference to the mandible as a site of myeloma is found in Beattie and Dickson's *Textbook of Pathology*. Because of the paucity of information existing in the literature concerning the solitary myeloma of the mandible the following case is recorded.

Case History

A man aged 39 was referred to one of us (R.S.) because of persistent swelling and great pain in the left side of the mandible. He gave a history of pain persisting for three weeks, at first localized in one of the left lower bicuspid and accompanied in the later stages by a slight swelling of the cheek. The tooth was first treated conservatively, but as no relief was obtained it was eventually extracted. The wound failed to heal and pain persisted, with discharge of pus from the socket. A little later the pain assumed a constant and dull character with attacks radiating to the ear and temporal region. These symptoms were accompanied by general malaise.

Inspection of the lower jaw revealed an oedematous inflamed mucous membrane extending from the canine to the molar region on the left side. Pus was draining freely from the wide-open socket of the extracted bicuspid tooth. The wound edges

were lacerated and undermined, and the base was covered with greyish granulations. There was some swelling of the buccal aspect of the mandible, but the lower border was palpable and no fluctuation was present. The process had involved the regional lymph nodes, causing hard and tender nodules, paresis of the left side of the lower lip, and slight trismus.

A lesion measuring 11 mm. in diameter was present in the region of the previously extracted bicuspid tooth. This was of osteolytic character without sharp definition and with little trabeculation. There was no evidence of the presence of root fragments or sequestra. On the strength of the clinical picture and the radiological appearance (Figs. 1 and 2) a tentative diagnosis of osteomyelitis was made and surgical exposure advised.

Fig. 1

Fig. 2

At operation a large mass of soft granulations of maroon colour which bled freely on manipulation was found in the affected area, extending into and invading the mental foramen and the mandibular canal. It was thus found that encroachment upon the cortex and marrow of the bone of the mandible was far greater than had been suspected from the clinical picture. After thorough curetting of the bone cavity a specimen was taken for histological examination. The biopsy showed a true myeloma. No Bence-Jones proteins were found in the urine. A blood count showed: red cells, 5,000,000 per c.mm.; haemoglobin 88%; oxyhaemoglobin 12.1 g.; white cells, 6,500 per c.mm.

Histology of Tissue from Mandible—The histology was that of a plasmacytoma, or true myeloma of bone marrow (Fig. 3).

Fig. 3

The material received consisted partly of necrotic bone, the cancellous spaces of which contained collagen fibres, fibroblasts, lymphocytes, and polymorphonuclear leucocytes. There was thus evidence of chronic osteomyelitis associated with tumour formation. Critical examination of the plasma cells which constituted the neoplasm revealed the presence of mitotic figures and of hyperchromatic nuclei in moderate numbers. The identity

of the plasma cells was confirmed by staining with Unna and Pappenheim's methyl-green and-pyronine. It is to be noted that this tumour bears no relationship to the myeloid epulis or osteoclastoma.

The diagnosis of solitary myeloma having been established, the patient was referred for x-ray therapy to Dr. Phillip Flood, to whom we are indebted for co-operation with this treatment and for furnishing notes on the clinical progress of the case.

Conclusion

The myeloma is a true malignant neoplasm, which in this case proved responsible for the pain which had at first been attributed to simple toothache. Several theories have been advanced regarding the aetiology of these tumours. Trauma and chronic osteitis may have an influence on the malignant transformation of cells of the bone marrow. In the present case the histology reveals that an osteitic process can be traced in the tumour region. Such a deviation from the normal may have contributed to the formation of the growth. A thorough radiological examination did not reveal any metastatic tumours. The treatment of choice for plasmacytomata in this region is surgical removal followed by x-ray therapy (Gootnick, 1945).

SIGNIFICANCE OF THE GRAM TEST FOR BACTERIA IN RELATION TO PENICILLIN BACTERIOSTASIS

BY

MARIAM GEORGE, B.Sc., B.T.

AND

K. M. PANDALAI, M.Sc., Ph.D., A.R.I.C.

(From the Department of Biochemistry,
Indian Institute of Science, Bangalore)

We have already shown that nucleic acids possess the property of antagonizing the inhibitory action of penicillin on susceptible pathogens and that they can also reverse such actions (Pandalai and George, 1947a, 1947b). Further, nucleic acids restored original characteristics to bacterial cells which had undergone changes in morphology and Gram-staining reaction due to contact with penicillin. We also demonstrated that nucleic acids failed to have any of these effects on Gram-negative bacteria, such as *Bacterium coli*, normally insensitive to penicillin, but which, however, were inhibited by higher concentrations (George and Pandalai, 1947).

It is now known that some other antibiotics are Gram-sensitive. It has also been demonstrated (Henry and Stacey, 1943, 1946) that the staining quality characteristic of the Gram-positive organism is associated with the presence of magnesium ribonucleate within the organism, and that this substance prepared from commercial sources was capable of restoring the Gram-positive quality to bacteria from which it had been removed by 2% bile salt in normal saline.

We have studied the influence of added magnesium ribonucleate on the growth of Gram-negative organisms kept in contact with penicillin. It might be expected that in the presence of added magnesium ribonucleate the Gram-negative organisms which are ordinarily insensitive to

penicillin would in their life processes be more in agreement with the sensitive organisms, and consequently would be inhibited by lower concentrations of the drug. It was actually found that magnesium ribonucleate stood to Gram-negative organisms in just the same relation as nucleic acid stood to the Gram-positive organisms, in that it antagonized the inhibitory action of penicillin and allowed the organisms to grow from a non-viable condition produced by contact with penicillin. The results are given in Tables I and II.

TABLE I.—Showing the Influence of Magnesium Ribonucleate on the Penicillin Inhibition of *Bact. coli*

Penicillin Alone (Units per ml.)	Magnesium Ribonucleate Alone	Magnesium Ribonucleate and Penicillin	Broth C.
12.0 +	1/2,500 +++	1/2,500 { 12.0 ++ 15.0 ++ 17.5 ++	
15.0 -	1/5,000 +++	1/5,000 { 12.0 ++ 15.0 ++ 17.5 +	++
17.5 -	1/10,000 +++	1/10,000 { 12.0 ++ 15.0 + 17.5 +	

- indicates complete inhibition; + indicates growth; ++ fairly good growth; +++ very good growth.

TABLE II.—Showing the Reversibility of Penicillin Action on *B. coli* produced by added Magnesium Ribonucleate

Penicillin (Units per ml.)	Magnesium Ribonucleate Added			Broth C.
	After 3 Hours	After 6 Hours	After 24 Hours	
12.0 +	++	++	++	
15.0 -	++	++	++	
17.5 -	++	++	++	
20.0 -	++	++	++	++

The magnesium ribonucleate used was a neutral solution of the magnesium salt of pure yeast nucleic acid, and *B. coli* was the test organism. The results show, however, that the addition of magnesium ribonucleate to *Bact. coli* cultures does not help the organisms to become susceptible to lower concentrations of penicillin. This means that magnesium ribonucleate alone cannot convert the Gram-negative organism into a Gram-positive one, at any rate from the point of view of susceptibility to penicillin action. Even granting that magnesium ribonucleate has some far-reaching effects on an organism (Stacey, 1947) in its relation to the Gram test, it cannot be said to possess any special influence on the specificity of the inhibitory action of penicillin, as the susceptibility of certain organisms, such as *Streptococcus faecalis*, the gonococci, and the meningococci will still remain unexplained.

That the magnesium ions, quite apart from the ribonucleate moiety, in the magnesium ribonucleate exert a pronounced influence on the growth of *Bact. coli* in contact with penicillin is seen from the results given in Table III.

TABLE III.—Showing the Influence of Magnesium Ions on Growth of *Bact. coli* in the Presence and Absence of Penicillin

Penicillin Alone (Units per ml.)	Mg ++ Added as MgSO ₄ Solution Alone	MgSO ₄ and Penicillin	Broth C.
6.0 ++		6 ++	
8.0 ++		8 ++	
10.0 ++	0.1% +++	10 ++	
12.0 +		12 ++	
15.0 -	0.2% +++	15 ++	++
17.5 -			
		0.2% { 6 ++ 8 ++ 10 ++ 12 ++ 15 ++	

The minimum inhibiting concentration of penicillin for *St. coli* diminishes to about 50% of its original value when magnesium ions are present in the culture treated with penicillin. It is interesting to note that exactly the same type of results was obtained with a strain of *Shigella sonnei*. It would thus seem that magnesium ions have an interesting property of converting normally insensitive organisms to a state more closely resembling that of the sensitive pathogens, probably by altering their metabolic pathways. It is thus obvious that there is need for further work to assess the actual significance of (1) the reaction in its relation to sensitivity or otherwise of the respective pathogens to penicillin, and (2) the assumption (Haslett, 1947) that the ability to produce penicillinase may be tied up with the absence of magnesium ribonucleic acid in penicillin-resistant organisms. Work on these aspects is in progress.

We gratefully acknowledge our indebtedness to Prof. V. Subrahmanyam and Major K. P. Menon for their interest and helpful criticisms, and to the Council of Scientific and Industrial Research, under whose auspices this work is being carried out.

LUGOL'S SOLUTION IN FAILING LACTATION

BY

DAVID P. NICHOLSON, M.D., M.R.C.P.

Registrar, Paediatric Unit, County Hospital, Farnborough, Kent

The capacity for satisfactory lactation shown by individual women depends on the quantity of breast tissue available and its degree of differentiation. It is unlikely that hormone therapy can significantly alter the quantity of tissue available, but it may influence a poor breast temporarily to secrete more milk. Dried thyroid gland may increase the rate of milk production since it raises the basal metabolic rate, and there is experimental evidence that this increase in milk output may amount to as much as 20-30% of the daily output. This effect is only temporary, and ceases when the hormone is omitted (Engel, 1947; Folley, 1947).

Partial or total failure of breast-feeding is common. Robinson (1943, 1947a, 1947b, 1947c) has described the results of hormone therapy in women whose lactation is judged likely to fail. As a result of this work it was concluded that dried thyroid gland caused a greater increase in milk yield than any other hormone. In view of this finding Lugol's solution of iodine was tried, and was found to be very more successful. It is difficult to explain why this should be so, for it is known that thyroid extracts and iodine have opposite effects upon the abnormal B.M.R.

Robinson (1943) test-weighed the infant on the fifth day, and if the milk output was less than 10 oz. (284 ml.) it was considered likely that lactation might fail. In a consecutive series of 99 such instances where lactation was judged to be failing test-weighing was done daily until discharge and gain at the fourth week. Of these women 72 were treated with Lugol's solution in milk twice a day. (Lugol's solution: 5%

iodine in 10% aqueous potassium iodide.) This treatment was started on the sixth day and continued until discharge or until the output reached 16 oz. (454 ml.). Lugol's solution appeared to increase the milk output.

This work has been repeated in the present series using exactly the same indication of failure to establish lactation and the same dose of Lugol's solution. Test-weighing was done on the fifth day, and if the output was less than 10 oz. the case was admitted to the experimental series. Alternate cases were used as controls or given Lugol's solution as indicated. Unfortunately, routine test-weighing proved impossible after discharge, which was usually on the twelfth day after delivery. Concurrently all infants in hospital were test-weighed on the fifth and tenth days to provide an indication of normality. One serious difficulty was encountered in making the work strictly comparable, since in this maternity unit the technique of Waller (1937, 1947) is used both to encourage lactation and to avoid congestion. This involves antenatal and postnatal expression of the colostrum and milk and the administration of moderate doses of stilboestrol in the early phase of congestion. However, it was decided to use the milk output, as measured by test-weighing, as the indication of failure to establish lactation, but to record the total output (test-weigh and expressed milk) in the results. By this means it has been possible to estimate the effect of the iodine solution on total milk output whilst adhering to the criteria of Robinson: furthermore, in this way it is possible to ignore the sucking power of the infant.

Part of Waller's technique is to give stilboestrol early in breast congestion. Since it was considered possible that this might affect lactation adversely patients who had received stilboestrol were excluded from the trial series. Nevertheless test-weighing was done, and the results are recorded in the Table. In this particular group there were

Results of Tests

Group	No.	5th Day Output Bulb (oz.)	5th Day Mean (oz.)	10th Day Output Bulb (oz.)	10th Day Mean (oz.)
Normal at 5th day	151	2.330 (66.21)	15.4 (436.21)	3.019 (85.771)	19.9 (555.21)
Normal at 5th day. Stilboestrol given	11	1.90 (53.41)	17.2 (480.11)	17.2 (480.11)	23.0 (645.21)
Failed at 5th day. Stilboestrol given	43	2.33 (66.21)	15.4 (436.21)	3.02 (85.77)	19.9 (555.21)
Failed at 5th day. Controls	24	1.99 (55.61)	17.2 (480.11)	17.2 (480.11)	23.0 (645.21)
Failed at 5th day. Iodine given	19	1.67 (47.41)	15.4 (436.21)	3.02 (85.77)	19.9 (555.21)

54 cases. On the fifth day eleven had an output over 10 oz. and 43 an output less than 10 oz. This second group of possible failures who had received stilboestrol were not given Lugol's solution. The results in these two groups appear to indicate that stilboestrol does not adversely affect lactation itself, and since it diminishes engorgement and tendency to abscess formation it seems reasonable to continue using it in moderate dosage, provided that it has no harmful effects on the female reproductive system as a whole.

It will be seen from the above results that Lugol's solution appeared to have no influence upon lactation, at least not a beneficial one. This is at variance with the findings of Robinson and would seem to nullify her conclusions that iodine increased the milk output and that failing lactation depended upon a deficiency of iodine intake. On the other hand, so far as these figures go it can be seen that stilboestrol given in the first few days of lactation has no permanent deleterious effect upon the milk output. It was considered unnecessary to append the statistical material from this work, since it did not clarify the results.

Summary

Forty-three cases of failure to establish lactation were studied, and Lugol's solution was given to alternate cases. This did not appear to affect the milk yield.

Stilboestrol did not seem to affect lactation adversely.

My thanks are due to Mr. Rufus Thomas and Dr. Duncan Leys, in whose unit this work was done; to the nursing staff, who bore the great increase in labour entailed; and to Dr. F. H. Hackwood, superintendent, for his permission to publish.

Medical Memoranda

Gonorrhoea: A Plea for Diagnosis before Treatment

Even to the most impartial of medical men the plaint of genital discharge by a patient is apt at once to suggest gonorrhoea. That such a high index of suspicion should obtain is in its way commendable, but not quite so praiseworthy is the procedure sometimes adopted. These comments have been prompted by the tendency to administer sulphonamides and even penicillin to cases of urethritis and the like without first attempting to ascertain the cause of the discharge. The assumption that genital discharge is more or less synonymous with venereal disease is not confined to the uninformed and uncharitable layman. Too often the clinician, led astray by a history of coitus followed by genital discharge, takes for granted that the case is one of gonorrhoea. The next false step, prompted no doubt by a desire to cure the patient as quickly as possible, is to prescribe immediately what amounts to specific treatment without first obtaining bacteriological confirmation. Gonorrhoea is by no means the only cause of irritation of the lower genito-urinary tract.

But there are other aspects to be kept in mind—such as the effects of a wrong diagnosis on the state of mind of the individual and on the health of the community. Furthermore, gonorrhoea is capable of causing social repercussions, and it may lead doctor and patient alike into the witness-box. A categorical diagnosis of gonorrhoea, even if correct, is to most patients unwelcome; but a presumptive one, based merely on clinical impression to the neglect of modern diagnostic procedures, is quite unjustifiable, and amounts to professional negligence. A non-committal answer to the patient's question—a reply that the condition "may be gonorrhoea" and that it is "safest to treat as if it were"—may lead to gonophobia and may entail endless trouble before the unfortunate victim is rid of what are perhaps unnecessary fears.

INDISCRIMINATE DRUG TREATMENT

The epidemiological control of infectious genital diseases is becoming an important aspect of modern medicine, but proof or at least sufficiently reliable evidence of an infection in the individual is necessary before measures may be taken to trace and deal with the source of infection. The rapidity with which a few tablets of a sulphonamide or one injection of penicillin may efface all proof of gonorrhoea stultifies any belated attempts to establish a correct diagnosis on bacteriological grounds. Thus a source of infection continues to spread disease still further afield. The hasty and indiscriminate treatment of genital discharge with these drugs shows a complete lack of appreciation of the doctor's duty not only to the patient but to the community. Time and again the venereologist is requested to deal with a patient supposed to have gonorrhoea, only to find the task of arriving at a diagnosis impossible because of previous administration of one or other specific remedy.

The only proof of gonorrhoea is the demonstration of the gonococcus, and treatment should not be started until reasonably adequate measures have been taken to identify the organism. In these days of the rapid control of gonorrhoea with penicillin, when patients, particularly males, tend to seek advice early in their disease, the delay of a day or so while awaiting a laboratory report on a sample of pus is of little significance. In an acute urethritis, in males especially, treatment may be given almost immediately, provided a specimen of discharge is procured first; if the lesion is gonococcal it is almost certain that gonococci will be found. Greater caution is necessary in the case of females, or in any patient in whom the development of gonorrhoea is likely to be followed by important social or medico-legal repercussions, but there can never be any excuse for what virtually amounts to treatment without diagnosis.

The following instances are quoted as illustrative of these remarks.

AN ILLUSTRATIVE CASE

A married man was referred to hospital because of urethritis. The history revealed the following succession of events. Ten days previously he had extramarital coitus and four days later he had intercourse with his wife. Two days thereafter he developed an acute purulent urethritis, for which he consulted his doctor, who without taking any steps to substantiate bacteriologically the diagnosis of "probable gonorrhoea," had prescribed sulphathiazole; and some 20 g. had been taken before the patient visited the clinic.

It was obvious that the situation was likely to prove difficult in several of the aspects which together determine the spread and control of infection. Clinically, it seemed likely that the condition had been gonococcal; but the sulphathiazole had done its work, and, though there was some residual discharge, it was impossible to prove gonorrhoea. The diagnosis was therefore in doubt. There were also two other problems—that of dealing with a possibly infected wife, and the examination of the other woman, who might still be spreading gonorrhoea. These two difficulties were temporarily shelved by the patient's refusal, because of negative findings, either to have his wife examined or to divulge the identity of the probable source of his infection. Six weeks later his wife developed a gonococcal salpingitis. He then disclosed the identity of his extramarital partner. Reference to the clinic register showed her to be a patient undergoing treatment for proved gonorrhoea who, subsequent to infecting the patient, had done the same to another man, who had brought her to the clinic for examination.

The sequence of incidents and the dates of their occurrence showed that, had a bacteriological examination been carried out in the married man in the first instance, it was highly probable that the development of salpingitis in his wife would have been averted, and that the infection of the other male would also have been prevented, particularly as the woman in question had been persuaded without any difficulty to come forward for examination.

OTHER EXAMPLES

A married man arrived at the clinic distraught over the suggestion of his having acquired gonorrhoea. Accidental contagion is extremely rare in adults, and the only probable source of infection was his wife. The supposition of gonorrhoea seemed justified; he had a very acute purulent urethritis, but a smear and a culture showed it to be staphylococcal. His wife was interviewed, and gave a history of a chronic infection of one of her Bartholinian glands. Examination corroborated this, and pus obtained from the gland gave a pure growth of staphylococci. Both were successfully treated, but their mental relief meant far more to them than the cure of their symptoms.

The need for caution is shown in another case, also considered gonococcal. The condition was somewhat unusual—a chronic inflammation of the lower surface of the glans and the frenum with a meatitis and a mild mucoid discharge. Though seldom seen in a clinic for venereal diseases, the condition was fortunately recognized as diabetic.

In the presence of a genital discharge, gonorrhoea must certainly be proved or excluded. Two errors are to be avoided (1) clinical evaluation on naked-eye appearance alone, and (2) to begin treatment without previous adequate bacteriological examination. The plea for care in arriving at a diagnosis of gonorrhoea is put forward in the interests of the patient, the doctor, and the community.

 Chief Venereal Diseases Officer,
 Aberdeen Public Health Service.

Reviews

RECENT MEDICINE

Progress in Clinical Medicine. By Various Authors. Edited by Raymond Daley, M.A., M.D., M.R.C.P., and Henry G. Miller, M.D., M.R.C.P., D.P.M. (Pp. 356; with 22 text-figures and 15 plates. 21s.) London: J. and A. Churchill, 1948.

If a symposium on progress in clinical medicine is to fulfil its purpose the writers should not only record all recent advances in diagnosis and treatment that have proved their worth in practice but should also assess these critically and endeavour to assign to them their rightful place in the pattern of medicine. They should indicate the territories on which research both in medicine and the basic clinical sciences is advancing, and they should give references to original papers which will reward those who wish to delve more deeply into a specific problem. The sincerest tribute which can be paid to *Progress in Clinical Medicine* is that its authors achieve all these objectives. The 26 editors and their ten associates are young and active physicians each of whom has had a wide experience in his special field, and this is reflected in their contributions, which present in a relatively small compass a comprehensive survey and a balanced appraisal of those advances in medicine which we have seen in the last decade or two.

The scope of the book is indicated by the following topics, selected from many: control of infections by antibiotics and the sulphonamides; the sources and methods of infection; immunization; virus meningitis; congenital defects and rubella; modern developments in the treatment of gonorrhoea and syphilis; chancroid and lymphogranuloma inguinale; tropical diseases; peptic ulcer of the oesophagus and paraoesophageal hernia; the scope of gastroscopy; hepatitis; diabetes mellitus and spontaneous hypoglycaemia; surgery in cardiovascular and pulmonary disease; polyarteritis nodosa; giant-cell arteritis; Libman-Sacks syndrome; classification of nephritis; renal anaemia; hypertension; the Rh factor; folic acid; "B.C.G."; sarcoidosis; disk protrusions; clinical application of the electroencephalograph; exophthalmic ophthalmoplegia; thiouracil; psychosomatic medicine. These are a few of the newer subjects discussed, but there are also useful critical reviews of many old problems; there is, for example, an admirable and sober essay on the present status of the rheumatic diseases.

This book will help the busy practitioner to keep abreast of general medicine; it will enable the specialist to acquaint himself with advances in fields other than his own, and—this is likely to be its widest appeal—it will provide a supplement to the textbooks for candidates for higher degrees in medicine. It would be invidious, when each contribution is of so high a standard, to choose any for special praise; but the next edition (which must soon be needed) will be improved if the synopsis of our knowledge of vitamins is replaced by a chapter more in keeping with the rest of the book. It now recalls a wall chart issued by one of the manufacturing houses.

HENRY COHEN.

AMERICAN PIONEER

The Selected Writings of Benjamin Rush. Edited by Dagobert D. Runes. (Pp. 433. 55.00.) New York: Philosophical Library, 1947.

The name of Benjamin Rush (1745-1813) is one of the most highly honoured in the history of American medicine. He has been variously called, and not without good reason, "the American Sydenham" and "the greatest pioneer in American medicine." A graduate of Edinburgh University, where he received his M.D. degree in 1768, he studied also in London and Paris. Then he returned to Philadelphia, where he later became a successor in the Chair of Medicine to John Morgan, another Edinburgh student, who in 1765 had laid the foundations of medical teaching in America. Rush rendered valuable service during the yellow-fever epidemics which devastated Philadelphia towards the end of the eighteenth century, although his treatment consisted in copious bleeding and large doses of calomel and jalap. But he was not content to limit his activity to the profession of his choice. His achievements were as varied

as they were numerous. He was an indefatigable student of the natural sciences, and his writings embrace agriculture, chemistry, education, theology, and politics. In the field of public welfare he was an active humanitarian. He protested against slavery, capital punishment, and alcoholism, and he pleaded for the more humane treatment of criminals and of the insane. As a patriot he was one of those who signed the Declaration of Independence.

It is obvious that the writings of such a man are worthy of attention, and the 29 essays now reprinted in book form must cater for every taste, grouped as they are under the headings, "Good Government," "Education," "Natural and Medical Sciences," and "On Miscellaneous Things." The last chapter consists of a series of letters written during the outbreak of yellow fever in 1793, and they give a vivid picture of the epidemic, which was believed to have been caused by a putrefied cargo of coffee on one of the wharves. Rush himself was a victim, but recovered "owing to the speedy use of the new remedies." An account of his visit to France is contained in the essay "On Manners," in which he praises the politeness of the French, although he found the physicians of Paris "at least fifty years behind physicians in England and Scotland in knowledge." The return crossing from Calais to Dover took 23 hours. The essay "On Old Age" contains much sound wisdom and might well serve as a model for those who to-day expound "geriatrics" as a new science. Rush did not find that sedentary employment, loss of teeth, the use of tea and coffee, or baldness had any effect upon the duration of life. As aids to good health in old age he advises warmth of room and clothing, young company, and gentle exercise; while in disease his favourite remedies are opium and bleeding.

There is an admirable lecture to medical students on "Duties of a Physician." "Never appear in a hurry," "Study simplicity in prescribing," "Be familiar with the common diseases," "Do not despise home-made remedies," are a few of the aphorisms of Benjamin Rush. There is an interesting series of three "Lectures on Animal Life" which recall John Hunter's method of thought. The essays on "The Bible as a School Book," and on "The Amusement and Punishment which are Proper for Schools" might be studied profitably by teachers to-day. The editor is to be congratulated on his selection and on his praiseworthy service in recalling the philosophy of Dr. Benjamin Rush.

DOUGLAS GUTHRIE.

COMMUNICABLE DISEASES

Communicable Diseases. By Franklin H. Top, M.D., M.P.H., F.A.C.P., and Collaborators. Second edition. (Pp. 992; 95 text illustrations and 13 coloured plates. 42s.) London: Henry Kimpton, 1947.

The modern textbook, especially on a special subject, often smacks of the card-index system, and it is indeed a major task of the writer to assess critically and place in proportion all the different aspects which he discusses. When the first edition of this book appeared we commented on the pleasure it gave to read reviews of subjects every line of which revealed expert observation that had been carefully considered. In the second edition, greatly enlarged and amended, it continues to bear this hall-mark.

There are 14 new chapters, and they include up-to-date accounts of such diseases as coccidioidomycosis, epidemic diarrhoea of the newborn, infective hepatitis, and infectious mononucleosis. The first section of 170 pages is on general considerations, and we would pick out for special mention the chapters on home and hospital management written by nurses. They describe the most recent aseptic nursing techniques which reflect the best nursing practice. The discussion on serum reactions will seem rather extensive to British readers, for experience with refined antitoxins here has almost caused us to neglect such occurrences, but American workers have always emphasized them, and there is probably here an example of some national difference as yet unexplained. Perhaps because of recent experience the chapter on poliomyelitis proved to be particularly enjoyable. The Kenny method of management is given a fair, objective analysis. What is good is acknowledged, and the author concludes that "the acceptance of 'spasm' as an observable phenomenon is valid, 'alienation' is probably unnecessary, 'incoordination' does occur and 'muscle paralysis,' partial or total, is important."

We noted here and there a few weak points—for example, the laboratory diagnosis of smallpox is given little space and not emphasized sufficiently. Again, in a book whose illustrations are so excellent it is surprising to find that some of the x-ray reproductions are really bad and some might have been omitted with advantage. But these do little to detract from a volume of very high general excellence. Since the book is American it includes accounts of diseases of slight importance in Britain, but we can repeat the prophecy we made on the first edition—"This book will be greatly appreciated in this country by all who have to do with the management of infectious diseases."

T. ANDERSON.

ORIGIN OF MAN

Mankind So Far. By William Howells. The American Museum of Natural History Science Series. (Pp. 319; illustrated with drawings and photographs. 16s.) London: Sigma Books, Ltd. 1947.

The study of human variation—the province of physical anthropology—to a large extent consists in attempting to solve the problem of man's origin and evolution. In this field knowledge of man's remote primate and less distant anthropoid ancestry has been accumulating at an increasing rate owing to the direct evidence furnished by the fossil discoveries in Java, China, Africa, and Europe during the last twenty years, as well as to the labours of the comparative anatomist and physiologist. To-day the search covers a formidable territory the exploration of which demands some acquaintance with general biology, genetics, geology, archaeology, anthropometry, and statistical method, and it is not surprising that no satisfactory general account is as yet available. Prof. Howells's book on human evolution is therefore a welcome introduction to this large and varied subject. In only 300 pages he has managed to cover the whole story of man's origins, evolution, and racial differentiation.

The account starts with a description of the primate mammal-like reptiles of the Mesozoic age from which in due course evolved the placental mammals, and among these, from some generalized stock, arose the Primate order. Then follows a description, based on zoological and palaeontological evidence, of the evolutionary radiation of the Primates, which yielded in due course the *Prosimii* of to-day, such as the lemurs and *Tarsius*, as well as the *Anthropoidea*. He describes the Tertiary *Anthropoidea* that are ancestral to modern forms. He traces the divergence of the human stock in relation to the hominid affinities of the *Dryopithecinae* and the important group of South African man-apes. With the beginning of the Pleistocene period we find at last individuals erect in posture, bipedal in gait, and whose limb proportions and brain capacity foreshadow the emergence of *Homo sapiens*.

Prof. Howells presents this account in an eminently readable fashion in about 100 pages. In the succeeding 100 pages he describes and briefly discusses the whole array of fossil men of the Pleistocene period. Prof. Howells deals judiciously and cautiously with the hotly debated controversies common in human palaeontology—with the relation of Java Man to Peking Man, with the hominid affinities of the South African man-apes, and with the status of Neanderthal Man in relation to that of *H. sapiens*. He is perplexed, like so many others, by the 40-years-old dilemma about Piltdown Man. He is cautious in his views of the "high antiquity" of *H. sapiens* as evidenced in the Swanscombe skull. In his final section, where he describes present-day varieties of man, he discusses sensibly and clearly the subject of human races and racial classification.

J. S. WEINER.

The plates in Dr. R. R. Kracke's *Color Atlas of Hematology* (J. H. Lippincott; 30s.) are the same as in his larger volume on diseases of the blood. Unfortunately the colour rendering and the printing are not quite so satisfactory as in that beautiful work. The colour is too red, as in Plate 23 ("Chronic Myeloid Leukaemia"), or Plate 26 ("Subacute Monocytic Leukaemia"), or the application of the colours is inexact, as in Plate 17 ("Anaemia of Hemolytic Jaundice"). For all that, it is a good atlas at the price, and the text is a well-balanced summary of the blood diseases. Some of the more quarrel at the definition of the megaloblast as "the largest known recognizable precursor of the normal red cell," and the text is a little too easily misled about folic acid than a year or two ago. It is a book that could be put into the hands of the student and read with great advantage.

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

The Preparation of Solutions Isoosmotic with Blood, Tear, and Tissue. By C. G. Lund and others. (Pp. 173. 15s.) London: Heinemann Medical Books. 1947.

A monograph from the dispensary of the Bispebjerg Hospital, Copenhagen.

Tuberculosis in Young Adults. By M. Daniels and others. (Pp. 227. 30s.) London: H. K. Lewis. 1948.

The report on the Prophit Tuberculosis Survey, 1935-44, carried out under the auspices of the Royal College of Physicians.

Statistical Methods in Research and Production. Edited by Owen L. Davies, M.Sc., Ph.D. (Pp. 292. 28s.) London: Oliver and Boyd. 1947.

An account of statistics, with special reference to the chemical industry.

An Introduction to Medical Statistics. By H. M. Woods and W. T. Russell. 2nd ed. (Pp. 125. 8s. 6d.) London: Staples Press. 1948.

An introduction to vital statistics, statistical methods, and sampling.

Syphilis. By Henri Mathias. (Pp. 722. 600 francs.) Paris: Librairie Maloine. 1947.

A general account of the acquired and inherited disease.

A Manual of Homoeotherapeutics. By E. A. Neatby, M.D., and T. G. Stonham, M.D. 3rd ed. (Pp. 960. 32s.) London: Staples Press. 1948.

An introduction for practitioners and students.

Partnership in Education. By E. W. Woodhead and others. (Pp. 158. 7s.) Norwich: Jarrold and Sons. 1948.

Short accounts of different aspects of education.

The Nature of Disease Institute: First Annual Report. By J. E. R. McDonagh, F.R.C.S. (Pp. 174. 21s.) London: Heinemann. 1948.

The author elaborates his theory of the causation of disease.

Ocular Therapeutics. By W. J. Harrison, Ph.D., M.D. F.A.C.S. (Pp. 112. 18s.) Oxford: Blackwell. 1947.

A manual of prescriptions, with notes on treatment.

Sexual Endocrinology of Non-Mammalian Vertebrates. By L. H. Bretschneider and J. J. D. de Wit. (Pp. 146. 15s.) London: Elsevier (Cleaver-Hume Press). 1947.

A monograph on research carried out at Utrecht University during the war.

Midwifery. By Ten Teachers. Under the direction of Clifford White, M.D., B.S., F.R.C.P., F.R.C.S., F.R.C.O.G. 8th ed. (Pp. 564. 20s.) London: Edward Arnold. 1948.

A textbook for students and practitioners.

The Psychology of Behaviour Disorders. By N. Cameron, M.D. Ph.D. (Pp. 622. 25s.) London: H. K. Lewis. 1947.

The book is an attempt to bridge the gap between psychology and psychiatry.

Conference on Infertility, 1947. (Pp. 64. 5s. 6d.) Family Planning Association.

Papers on infertility read at the Oxford meeting in 1947.

Public Health Administration in the United States. By W. C. Smilie, A.B., M.D., Dr.P.H. 3rd ed. (Pp. 637. 32s. 6d.) New York: Macmillan. 1947.

A general account of modern administrative methods in the U.S.A.

Modern Trends in Ophthalmology. Vol. II. Edited by Arnold Sorsby. (Pp. 600. 3 guineas.) London: Butterworth. 1948.

A variety of articles by authorities on different aspects of ophthalmology.

Dietetics in General Practice. By L. Cole, M.A., M.D., F.R.C. 2nd ed. (Pp. 160. 8s. 6d.) London: Staples Press. 1948.

In this edition some diets have been modified to accord with present circumstances.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY MAY 29 1948

BASIC MEDICINE

In the turmoil of medical politics the B.M.A. has found time to remind the profession and the public of its concern with the cultural activities of Medicine by publishing what may come to be considered as the most significant of its special reports—the Report of its Medical Curriculum Committee, now issued as a book under the title of *The Training of a Doctor*.¹ Under the chairmanship of Dr. Henry Cohen, Professor of Medicine in the University of Liverpool, the Committee has spent two searching years in its exhaustive review of the most fundamental problem of medical life—education; and to help it in its task men and women distinguished in various fields of medical work have given it unstinting aid. The Committee has been brilliantly served by its Chairman, Prof. Cohen, to whose enthusiasm and inspiration the form and content of the report owe so much. We print elsewhere an extended summary of the book now published, which deserves the repeated study of those responsible for training the doctor and of those perpetual students to whom qualification is but an introduction to a lifetime of study.

In his address² at the Annual Meeting of the B.M.A. in Montreal in 1897 William Osler said: "Undue reverence for authority as such, a serene satisfaction with the *status quo*, and a farious objection to change have often retarded the progress of Medicine." There is none of this in the present report. On the contrary there is a divine discontent with things as they are, along with sustained constructive thinking that illustrates the general theme with modern instances. Many who teach may disagree with some of the recommendations of the Committee; much of what it advocates may be impracticable, at least for the present; but the report is a challenge to medical educationists, and we may hope that the essence of its message will not be borne down by what Osler called "the weight of a complacent conservatism."

Of recent years there have been other outstanding reports on medical teaching, notably of the Goodenough Committee and of the Royal College of Physicians. But the B.M.A. Committee considers that the changes required in the curriculum are far more radical than is generally conceded. It advocates that changes "should be based on educational experiment rather than on surmise and presumption," and it issues its first challenge by refusing to "accept in its full implication the oft-reiterated view that the aim of the curriculum should be to produce a competent general practitioner." General practice is looked upon as a special form of practice founded on principles common to the study of medicine—what might be termed

basic medicine. General medicine should be taught "as the basic clinical subject" and not be looked on as what is left after the specialties have been skimmed off. What is needed is the sense of the unity of medicine. Linked with this is an appeal for the renaissance of the general physician: "One of the primary reforms should be the return of the physician with a general outlook." It is he who should be the co-ordinator of medical teaching and the prevailing influence in the medical school. The Committee deplores the fission of teaching into compartments of uncorrelated knowledge. The unfortunate student is the victim of specialist teaching and special investigations. With each new incursion of the pure sciences into medicine new facts are piled on to the heap of the old that constitute the curriculum. Psychological medicine, social medicine, medical statistics—these and other subjects take on an added importance, and up goes the cry for additions to the curriculum and subsequently for that modern money-getter for the corporations, the special diploma. The curriculum grows like a coral reef, and the student looks in vain for a trustworthy chart in the ocean of medical knowledge.

The Committee repeats the indictment made often enough in recent years that the rapid advances in medical knowledge made during the past half-century "have not resulted in a proportionate improvement in the general efficiency of medical practice." It regards this as "a matter for regret and concern." The fault lies with the method of education, and the Committee considers that fundamentally it resides in the conception of medicine and medical training on which the curriculum has been based. The Committee's conception is exemplified by its proposals. It comes down heavily against a vocational bias in school education, and disagrees with the views of the Norwood Committee, supported by the Goodenough Report, that a school-leaving examination at the age of 18 might admit the student to "the medical curriculum proper." And it disagrees, too, with the suggestion in the Goodenough Report that the boy or girl with good elementary grounding in the basic sciences need spend little time on physics, chemistry, and biology in starting the medical course. The Committee repeats Flexner's saying: "The Physician should first of all be an educated man." The one way to prevent this is premature specialization at school. It is only the rare person who in later life overcomes the handicap of being forced too early into vocational studies. In an age of shifting material values and intense specialization a sound educational grounding is more than ever necessary if the medical man is to be other than a mental mechanic. It is to be hoped that the Committee may press its views with propagandist zeal on those who would use the last year at school to short-circuit the student into his medical studies. Having stressed the need for a broad education at school, the Committee advocates that the first university year should be devoted to physics, chemistry, and biology. The student will have the great advantage of learning from teachers of university status and training at a time when his mind is beginning to walk on legs of its own.

Of all the Committee's many excellent recommendations for medical education we consider their proposals for

¹ *The Training of a Doctor*. London: Butterworth, 1948. 7s. 6d. net.

schooling and the first university year—proposals not strictly applicable to medicine—the most important. Up to 18 the boy or girl needs the mental discipline and freeing of the intellect that can come only from a liberal education. If the student then decides to “go in for” medicine he needs to be thoroughly grounded in the basic sciences and in the scientific method if as a doctor he is to be other than a casual but hopeful purveyor of the numerous remedies now available to him. The modern doctor who is imbued with a sense of vocation must have more than school knowledge of chemistry, physics, and biology if he is to apply with understanding the findings of modern medical science. To the scepticism of the scientific outlook he must join the wide sympathies and culture that come from a study of the humanities if he is to apply with judgment his knowledge to the care and cure of his fellow men. It is a hard and uphill task; but Medicine is a high calling—not a trade.

The student passes from his first university year in the basic sciences to what the Committee calls “the preclinical period,” a term it regards as unsatisfactory because the study of the normal man is an integral part of clinical work. It pleads for closer co-operation between the teachers of anatomy and physiology and deplores the growing scarcity of medically qualified teachers with the required expert knowledge in these subjects. Some of the best medical men, the Committee believes, are attracted to whole-time clinical appointments because of the better financial rewards. Higher salaries and improved prospects for the whole-time teacher of anatomy and physiology would do much to even the balance. The Committee levels the usual criticisms against the mountain of anatomical and physiological facts the student has to acquire, and stresses that it is the anatomy of the living that should be taught, not the anatomy of the cadaver; a bone is not a dead and rigid structure but a living process. Not everyone, however, will agree that less time should be spent on the experimental physiology of animals. Animal experiments are of the first importance in medical research, and the technique of the laboratory should be part of the student's intellectual equipment even though few of them will return to the laboratory after qualification. And it is well to be reminded that man is an animal, sharing with other vertebrates a common structural plan and surpassing them in mental equipment, the study of which the Committee considers should begin in the preclinical period, the course in normal psychology to follow the study of the anatomy and physiology of the central nervous system.

Throughout its report the Committee urges the need for “an integrated and synoptic view” of each phase of medical education—of the basic sciences, of human biology, of clinical medicine, of the human being as one whole compact of mind and body. What detracts from this view, whether tendencies in teaching or burdensome detail in what is taught, should be done away with. The approach to clinical medicine should be based “on the conception of disease as a disturbance or disequilibrium in the structure and function of the organism.” The Committee regards the concept of diseases as clinical entities “simply as a descriptive convenience.” There is a danger in the

self-satisfaction that comes from attaching a diagnostic label, but one cannot lightly discard the classification of certain facts of observation into clinical entities “simply as a descriptive convenience.” To state that a person has a disturbance of the lung is one thing; to correlate facts of observation into the clinical entity of pneumonia leads to greater diagnostic precision. The danger of the label is that it tends to make the student think of the disease labelled as something static. This tendency is increased by the splitting of Medicine into specialties and the segregation of patients with the same disease into special wards, blocks, or institutions. It is understandable that the research worker must narrow his focus, but for the practice of Medicine is it really necessary that there should be heart specialists and lung specialists? And among the latter is there really room for those who deal only with one disease of the lung, even though the segregation of tuberculous patients makes this difficult to avoid? At least the mediastinum seems to have escaped the notice of those who have been busy splitting up the body into compartments of special practice. Sensible of the dangers of this fissiparous tendency and of its ill-effect on the student the Committee presses for the return of the general physician, and recommends that “general physicians of broad interests should be appointed to Chairs of Medicine and that they should be responsible, with the assistance of a Committee of the senior teaching staff, for the organization of the teaching of the whole of clinical medicine.” A movement on these lines would help towards the integration of Medicine, towards the synthesis many feel is now so much needed in what we call the art and science of Medicine. And such a synthesis would be facilitated by keeping alive the student's interest throughout his whole clinical period in the basic principles of general pathology. The Committee regards the divorce of pathology from clinical medicine as “one of the most serious defects of the present medical curriculum,” and would bring the pathologist into the wards; so, too, the Professor of Pharmacology should be given “a definite status in ward teaching.”

We note the Committee's opinion that the knowledge gained from attendance at operations is not worth the time spent watching and waiting; that anaesthesia is now a highly developed specialty; that present methods of training in obstetrics and gynaecology are not good enough; that paediatrics is one of the most important subjects in the curriculum; that the standard of training in psychiatry would be improved if general physicians would take more interest in the psychiatric aspects of illness; that socio-clinical conferences should be arranged for joint teaching; that the teaching of public health and social medicine must be reorganized “if the student is to become imbued with the concept of the prevention of disease and with the importance of the study of the social setting of the individual in health and disease.” For the “intern year” the Committee favours trial of the method whereby the intern is assigned both in-patients and out-patients as they are admitted to hospital and not as medical or surgical cases “at least six months will be devoted to this integrated study of patients and not be divided into ‘medical’ and ‘surgical’ appointments.”

BASIC MEDICINE

There is not the space here to do more than touch upon some of the points in a report that contains so much solid matter condensed in so readable a manner. The stress throughout it on the integration of Medicine, on the unity of Medicine, on the synoptic view, comes at a time when many feel with the late F. G. Crookshank³ that "the twentieth century has as yet produced no such ordered and orderly presentation, as did the sixteenth, of the known facts concerning disease: duly set out and interpreted with respect to definitions, stated first principles, enunciated doctrines and terminal conclusions: embracing (as must any Science of Medicine) consideration of metaphysical problems of one kind or another, whether in relation to mental disease or to the understanding of the normal functioning of the body. . . ." Crookshank inveighed against the accumulation of "passive perceptions," and the B.M.A. Curriculum Committee is at one with him. William Harvey prefaced his *De Generatione Animalium*⁴ with a discussion "on the manner and order of acquiring knowledge," following Aristotle, whom he called "my leader." "How base a thing," he wrote, "it is to receive instruction from others' comments without examination of the objects themselves, the rather as the book of Nature lies so open and is so easy of consultation." And again: "We are, I say, to strive after personal experience, not to rely on the experience of others; without which, indeed, no one can properly become a student of any branch of natural science. . . ." How this may be attempted at a time when we may feel less optimistic than Harvey about the ease with which the book of Nature may be consulted is shown in the B.M.A.'s exemplary Report on the Medical Curriculum.

PULMONARY OEDEMA

The problem of pulmonary oedema becomes ever more complex as knowledge about the condition accumulates. The simple explanation, based on the experiments of Welch,¹ of unbalanced action of the two ventricles of the heart was for long accepted by clinicians, if not in all forms of pulmonary oedema at least in those associated with cardiovascular disease. This explanation will certainly not now bear critical examination. In last week's *Journal* we published Prof. G. R. Cameron's Sydney Ringer Memorial Lecture, in which he presented a useful review of this difficult subject. His analyses of the necropsy findings in 100 cases of pulmonary oedema and of the frequency with which pulmonary oedema was found at necropsies of patients who had suffered from various selected types of disease and injury revealed the usual preponderance of diseases of the cardiovascular and central nervous systems. The finding that 11 cases out of 100 of pulmonary oedema were associated with obstruction of the pulmonary veins by carcinoma seems rather unexpected, but cannot be interpreted without knowledge of the source of the necropsy material. Among cardiovascular diseases, pulmonary oedema was present at necropsy in 86% of patients with hypertension, 74% with chronic nephritis, 68% with coronary obstruction, and 65% with mitral stenosis. In cerebral haemorrhage the incidence of pulmonary oedema was 67%, and in fractured skull 63%. Of 28 patients dying

with multiple fractures of bones, excluding the skull, 17 (61%) developed the condition.

Of the lung-irritant gases, among which Cameron and his co-workers have found that ketene has a place, phosgene has been most intensively studied. The mechanism by which pulmonary oedema is produced seems to be the same for all these gases and in all animals, with minor variations. Phosgene is hydrolysed on contact with the lining membranes of the respiratory tract, so that none of it reaches the circulation and its effects are produced locally. It has proved difficult to obtain evidence of these effects in the endothelium of alveolar capillaries histologically, but Short² has demonstrated changes in the mitochondria of these endothelial cells after exposure to phosgene before the capillaries begin to leak. After a latent period fluid leaks from the capillaries into the pulmonary air spaces. At first this is almost free from cells, but has a high protein content. The increasing pulmonary oedema can be shown in most animals to be closely followed by decrease in the circulating blood plasma. An exception is the rabbit, in which no haemoconcentration took place despite massive loss of plasma into the lungs: if, however, rabbits were kept on a dry diet before exposure, haemoconcentration usually occurred, and this is taken to suggest that the rabbit normally has a large available store of fluid on which to draw. Using the technique of cannalization of the right lymph duct developed by Drinker³ and his school, it was shown that as pulmonary oedema develops after exposure to phosgene the flow of lymph from the lung steadily increases, thus resembling other forms of pulmonary oedema. The main lymphatic channels from the lung are relatively narrow, and it is presumably through this increased flow can no longer be removed through them that oedema develops. Physiological saline is readily removed from the air spaces, probably directly into the blood capillaries, but serum persists in the lungs for about four days and is removed probably through the lymphatics. The abnormal permeability of the capillaries after gassing with phosgene leads to the rapid loss of transfused plasma into the lungs; Courtice and Foss⁴ showed that in gassed dogs and goats transfused plasma and concentrated serum disappeared rapidly from the circulation and the animals' general condition worsened. In experimental phosgene oedema no evidence of interference with the pulmonary circulation can be found until the last stages; Cameron is satisfied that the capillary thrombosis described by Shaw Dunn⁵ is due to stasis secondary to haemoconcentration. After careful consideration of what is known about the haemodynamics of the lesser circulation Cameron concludes that pulmonary oedema may result from injury of the lining cells of the lung capillaries alone.

The absorption of pulmonary oedema may be followed by pulmonary oedema. There has been great interest recently in the effects of substances allied to thiourea. Jones⁶ showed that α - and β -naphthyl thiourea and α - and β -dinaphthyl thiourea in toxic doses caused

massive pleural effusions and pulmonary oedema which seemed to be due to a specific action on the lung capillaries. Cameron considers that the oedemas associated with the absorption of acetic and butyric ethers, iodides, and methyl salicylate are caused in the same way, and points out that localized oedemas of some other tissues are caused specifically by certain other drugs.

Turning to the pulmonary oedema associated with nervous disturbances, Cameron, like Daly,⁷ criticizes bilateral vagotomy as a method of producing neurogenic oedema, since it may result in aspiration of oral secretions into the lungs with anoxia, and if pulmonary oedema develops the responsible factors are difficult to identify. He has found that the injection into rats intracisternally of a solution of fibrinogen followed by thrombin, producing a fibrin film within the cisternae, leads to acute pulmonary oedema, fatal within a few minutes. Dividing the vagi reduces or prevents this oedema. Cameron thinks it likely that raised intracranial pressure is a link in the chain of causation of the pulmonary oedema produced by this procedure. After reviewing what is known as the vasomotor nerves of the lungs, he suggests that the question of a nervous mechanism controlling the permeability of the lung capillaries should be re-examined.

Pulmonary oedema in cardiovascular diseases is commonly basal, though in uraemia⁸ it is often perihilar. Cameron offers no explanation of this peculiarity of uraemia; Drinker's³ finding that increased breathing movements help to remove fluid from the lungs suggests the possibility that the hyperpnoea of uraemia, which would increase expansion especially at the periphery of the lungs, may be responsible for the relative freedom of the bases from oedema. Cameron accepts the emphasis placed upon left ventricular failure in the pulmonary oedema of cardiovascular disease, even though he confesses to "difficulty in sorting out the state of the two ventricles." He has been unable to confirm Welch's results in his laboratory; ligation of the rabbit's aorta near the heart did not constantly give rise to lung oedema. The mechanism of adjustment between the two circulations is such that only a transitory dissociation of output from the two ventricles is conceivable. Cameron considers that, in addition to the higher head of filtration pressure which can be the result of a rise of pulmonary venous pressure, there are other causal factors in the development of pulmonary oedema. Among these are anoxia, which has been stressed by Drinker,³ dyspnoea, bronchitis, and depletion of the plasma protein. The inclusion of dyspnoea, presumably due to other conditions, in this list of possible contributory causes of pulmonary oedema shows clearly the divergence of view from the hypothesis that the condition is due to left ventricular failure, in which paroxysmal cardiac dyspnoea is customarily regarded as the earliest stage of an attack of pulmonary oedema. Studies of heart-lung preparations have confirmed that pulmonary arterial and venous pressure must be grossly raised before oedema occurs, that oedema may appear before any change in pulmonary arterial pressure, and that changes in the perfused blood favour the development of oedema, presumably by damaging the capillary endothelium. In the latter

connexion Daly⁷ has found that perfusing a heart-lung preparation of a dog with human blood causes the rapid development of severe lung oedema, though perfusion with horse blood keeps the lungs dry.

Pulmonary oedema fluid produced in widely different ways has been found in Cameron's laboratory to contain a high proportion of protein. Such diverse methods as ligation of the aorta, oxygen poisoning, and intravenous injection of methyl salicylate produced oedema fluid the protein content of which varied from 4.25% to 7.62%. Cameron considers that this indicates that the unifying principle is a disturbance of capillary permeability, and suggests that future investigations should be directed to determining whether endothelial permeability is affected by nervous influences, by alteration of blood flow, and by environmental variations, especially in gaseous exchange. Among these environmental variations may perhaps be included capillary toxins, which Daly⁷ suggests should receive more attention in investigations of clinical pulmonary oedema.

REPRESENTATIVE MEETING

A Special Representative Meeting is being held on Friday of this week to consider the result of the April Plebiscite and the three Recommendations of the Council, published in the *Supplement* to the *Journal* of May 8. A large number of motions and amendments have been submitted by Divisions, and in their bulk constitute a formidable agenda. Many of these are couched in a critical tone, and it may be expected that controversy will be lively. Since the last meeting of Council a B.M.A. deputation has had discussions with the officers of the Ministry of Health and on May 25 with the Minister himself. The statement of the position resulting from these discussions will be placed before the Representative Meeting, and it is hoped to comment on the general situation in next week's *Journal*.

THE CAMBRIDGE MEETING

Sir Lionel Whitby, President-Elect of the British Medical Association, makes an appeal in our correspondence columns this week for members who intend to be present at the Annual Meeting at Cambridge in June to send in their applications for accommodation at once. Forms of application have been printed in three recent issues of the *Supplement*, and the same form is printed on a sheet loosely inserted into this week's *Journal*. Sir Lionel points out that only a small number have applied for accommodation, and it is essential for those who are organizing the meeting to have a rough estimate of the numbers likely to attend so that firm bookings may be made. Before the war it was usual for the majority of those who attended the meeting to apply for accommodation only two or three weeks before the meeting was actually held. This was a cause of dissatisfaction to those responsible for the arrangements of the meeting, but in the easy days of peace it was not too difficult to deal with the last-minute rush. To-day those responsible for the organization of the meeting are faced with every possible difficulty, and we would urge

members to apply at once out of courtesy to our host, the Cambridgeshire and Huntingdonshire Branch of the B.M.A. This Branch is determined to make this, the first Annual Meeting to be held since 1939, a memorable occasion and worthy of the best traditions of previous annual meetings. The setting for this year's meeting is ideal for members of a learned profession, and those who do not know Cambridge and the treasures it possesses will not wish to miss the opportunity of being there in less than a month's time.

ROYAL SOCIETY CONVERSAZIONE

Many of the exhibits at the Royal Society conversazione on May 20 again displayed the uncanny ingenuity of the human mind when it inquires into the perplexities of nature. Of particular interest to medical men were the demonstrations of phase-contrast microscopy. The illuminating beam is treated in such a way that variations in phase are converted into variations in amplitude, so that parts of the living cell with different refractive indices, such as cytoplasm, chromosomes, and mitochondria, are clearly distinguished as light or dark without being stained. The resolution obtained is about double that with ordinary light. The chromosomes appeared as dark threads and blobs in the fresh preparation of sarcoma cells shown by the National Institute for Medical Research; in greatly enlarged photomicrographs they could be seen in the various stages of mitosis. A short film that speeded up the mitotic dance gave a remarkable front-row view of the chromosome chorus performing its evolutions in the dividing osteoblasts and fibroblasts of the embryonic chick and in the fibroblasts of the frog and newt.

The Natural History Section of the British Museum displayed a number of insects, molluscs, and other specimens, immured, like flies in amber, in glass-clear blocks of methyl-methacrylate ("perspex"). The specimens are imbedded in the liquid monomer, when it is then polymerized to the solid perspex by irradiation with ultra-violet light. This technique should prove useful in preserving pathological specimens, obviating the fraying and subsequent disintegration that often take place in liquid preservatives. The Wellcome Research Institute exhibited a biologically balanced aquarium for the culture of the Egyptian snail vectors of schistosomiasis—*Planorbis boissyi* and *Bulinus truncatus*. The most suitable food for these molluscs is boiled lettuce; they will accept certain other green vegetables such as boiled cabbage, but no doubt the laboratory is all the better for not smelling like a hotel kitchen. Growing plants regulate the exchange of oxygen and carbon dioxide, and oligochaete worms consume the excretory products and decaying vegetation. An apparatus shown by the Cambridge Instrument Company measured the percentage of oxygen in a gas by the changing of its paramagnetism with temperature. The gas flows across the ends of a small tube of which half is in a strong magnetic field. The middle part of the tube is heated by a centre-tapped platinum resistance which forms two arms of a Wheatstone bridge. If the gas contains oxygen a flow is set up in the tube which cools the heater wires, causes a relative change in the resistance, and throws the bridge out of balance; the result is recorded electrically in terms of the oxygen content.

An ingenious labour-saving device—for the laboratory rather than the home—was an ultrasonic memory system designed by the Cambridge University Mathematical Laboratory for an electronic calculating machine. Numbers are converted into electric impulses, which are then

passed in the form of ultrasonic waves into a column of mercury about four inches long. After traversing the column they are converted back into electric pulses, amplified, tidied up, and returned to the input. They thus circulate indefinitely and are available when required. A problem in rheology—the study of the flow and deformation of matter—afforded light relief to those who enjoy ball games. Silicone putty, which appears like ordinary putty and is of a similar consistency, has the peculiar property that when a stress is applied to it for a very short time it behaves as an elastic solid. It flowed slowly from the orifice of a reservoir on to a platform about 18 inches below, where it spread out into a flattened mass. A gravelly, enthusiastic audience dropped on to it some metal balls, which, instead of sinking in with a dull thud, bounced off with the surprising rebound of acrobats from a spring mattress.

ANNUAL REVIEW OF MICROBIOLOGY

It is becoming difficult to an increasing degree for workers even in a fairly restricted sphere of medicine to keep track of the literature of their subject. This difficulty is met to some extent by abstract journals and by journals comprising monographs or reviews on selected subjects. There are also annual publications devoted to keeping their readers up-to-date, and among the most valuable of these to academic workers in particular have been the *Annual Review of Biochemistry* and of *Physiology*. It will be welcome news to many that there is now an *Annual Review of Microbiology* published by the same academic organization. The 1947 volume is now available, and the subjects and authors for 1948 are listed on its dust-cover. The present volume contains seventeen chapters, of which fourteen are by American and three by British authors. D. D. Woods writes on bacterial metabolism, E. F. Gale on the nitrogen metabolism of bacteria, and E. M. Lourie on chemotherapeutic agents. Antibiotics naturally get a chapter to themselves, and it is interesting that about sixty distinct substances are considered worthy of more or less detailed description. They are classified according to their sources, beginning with the various substances which have been obtained from organisms of the *B. subtilis* type. Since this was written, aerospirin has been favourably reported on by G. Brownlee and S. R. M. Bushby,¹ particularly for the treatment of whooping-cough, and R. K. Callow, R. E. Glover, P. D'Arcy Hart, and G. M. Hills² have had promising results with licheniformin in experimental studies of the treatment of tuberculosis. The antibiotics of the genus *Bacillus*, which of course include gramicidin, the first bacterial product ever shown to be capable of therapeutic action, are worth watching.

There is an interesting chapter on immunization by J. Freund, who describes the remarkable effects of vaccines administered in oil emulsions, and another on the quarantary ammonium compounds, a class of disinfectant about which exact knowledge and clear thinking increase in importance *pari passu* with their popularity. T. Francis was the author-selected to write the chapter on the respiratory viruses. Other subjects are immunochemistry, industrial fermentations, two chapters on fungi, and four on various aspects of the study of protozoa. It would be easy to criticize this list of subjects by pointing out others which might have been worthy of inclusion, but the choice has been well made, and every chapter contains not only a mass of information and a valuable list of references, but the individual views of an authority on the subject.

MEDICAL EDUCATION: A NEW APPROACH

REORIENTATION OF THE CURRICULUM

(B.M.A. Special Committee Report)

The Council of the British Medical Association three years ago set up a Special Committee to review, in the light of later developments and the requirements of modern practice, the B.M.A. Report on Medical Education, published in 1934. The Special Committee was fortunate in its choice of Chairman—Prof. Henry Cohen, who holds the Chair of Medicine in the University of Liverpool. The other twenty members represented many branches of medicine. They included three deans of medical schools or faculties, seven senior physicians or surgeons attached to teaching hospitals, four general practitioners, one representative of medical students, and the five chief officers of the Association, four of whom are also in general practice. Scotland was represented by five members.

The Report now issued, a document of 150 pages, covers the whole subject of undergraduate education, from the pre-university period to a compulsory year of internship. The Committee received oral or documentary assistance from some eighty authorities on the subject. The result is a contribution of the first order to the literature of medical education. The Report approaches the subject on a broad basis of criticism, destructive and constructive, and it is written in an individual and attractive style as though it were the work of one able pen instead of the combined effort of twenty-one people with differing points of view. So impressed was the Council with the Report submitted to it that it has agreed to set up another committee—though this has not yet been appointed—to carry the subject forward on to the postgraduate level.

A Drastic Overhaul

In the early part of its Report the Committee recommends some radical changes in premedical and preclinical instruction, but the most drastic overhaul is proposed for the clinical period. It believes that a new approach to medical education and practice should be based on the conception of disease as a disturbance or disequilibrium in the structure and function of the organism, the idea of "diseases" as clinical entities being regarded simply as a descriptive convenience. The educational implications of such a change, as the Report states, are far-reaching.

Perhaps the key passage to the whole outlook of the Report is to be found in the middle of it, in the chapter headed "The Student and the Patient":

"The Committee believes that, whatever the cost of reconstructing the curriculum, we should return to first principles and so remodel the training of our students that they will base their future practice on an understanding of each patient as a 'whole,' using the resources of the specialties as aids to diagnosis and treatment.

"... One of the most serious defects in present-day medical training in the clinical period is the failure (i) to regard the patient as a whole, and (ii) to teach the principles and practice of general medicine. If the medical practitioner is to treat his patient 'as a whole' he must be taught how to do so in his undergraduate years, and he cannot be properly trained in this conception by the present method of dividing medicine into a number of distinct and separately taught compartments."

The time has come to remodel the clinical curriculum so as to provide the student with a thorough basic training for modern medical practice. He must be taught the general principles of medicine, trained to diagnose and treat common ailments in minor medicine and surgery, and to recognize conditions for which he should summon expert help. More specifically, he must learn the functions and scope of medicine, the nature of health and of disease, the fundamental principles of general pathology, the method and purpose of diagnosis, the general principles of prevention, treatment, and after-care, the causation, diagnosis, and treatment of common ailments, and such special pathology, medicine, and surgery as will enable him to recognize emergencies and conditions for which special measures are required.

This cannot be achieved by requiring him to attend courses in the several departments, each organized without liaison with other departments. Yet this is what occurs in most medical schools to-day, "with the result that the newly qualified doctor embarks on responsible practice with an idea of medicine as an inchoate collection of facts isolated in special departments, and he quickly finds that his training has failed to give him competence to deal with the ordinary problems of his everyday professional life."

The Integrated Curriculum

The clinical curriculum should be a single whole, planned by a committee of the professors or senior members of the teaching staff. Transition from the preclinical study of the normal should be effected by introducing the student to the basic principles of general pathology, and the remainder of the clinical period should be devoted to the study of the foundations of the main branches of medicine, with short courses in special subjects. All subjects should be dovetailed into one another. The courses in special subjects should deal mainly with the scope and potentialities of diagnosis and treatment in specialties with highly expert techniques, but such teaching should be incorporated where possible in the courses of general medicine, surgery, and pathology. Topics such as social medicine and psychiatry should be regarded as integral to all aspects of medicine, and so far as possible dealt with in relation to the wider subjects rather than as distinct and separate courses.

In the Committee's view, teaching-hospital consultants and specialists at present tend to be concerned too much with the status of their specialties; thus the student gets a distorted view of the relationship between the specialties and general medicine. One means of restoring the balance will be by the return of the physician with a general outlook. General physicians with broad interests should be appointed to chairs of medicine, and be responsible, with the help of a committee of the senior teaching staff, for organizing the teaching of all clinical medicine. Specialists would teach special aspects, but these would be fitted into the general plan. The abrupt division into medical and surgical wards may have to go. "Measures that disintegrate medicine should be avoided; all that fosters an attitude which regards the patient as a 'whole' should be supported."

Methods of Teaching

The return of the physician with a general outlook would meet the criticism that although the majority of students will become general practitioners they are taught by consultants and specialists, and thus get a false perspective of the conditions of general practice. Some older men in practice can recall being taught by teachers who, outside the medical school, were general practitioners, usually general physicians of the best type. Such teachers have been largely superseded by specialists. But the Committee finds difficulty in accepting the proposal that the general practitioner should be brought into the teaching hospital or the student sent to the general practitioner. The present generation of doctors has been educated in a consultant atmosphere, and it might be difficult to find a sufficient number of really suitable general practitioners who have developed the broad outlook desired and also have the ability and inclination to teach. Other practical difficulties are pointed out, such as the strain which the continuous presence of even one student might impose upon a practitioner, and the possible resentment of patients and relatives at the attendance of a student. In these circumstances the student himself might receive only doubtful benefit.

The Committee notes as one of the shortcomings of the Goodenough Report the use of the cliché "teaching and research," as though they were synonyms; usually they are antonyms. Lecturers and professors should be appointed for their skill as teachers. Lectures should have more care and forethought than is often given to them. The good lecturer avoids a textbook presentation and makes no attempt to cover the whole field. The criterion of the acceptable teacher is expressed in Pope's couplet:

Men must be taught as if you taught them not,
And things unknown propos'd as things forgot.

The good teacher will remember that the student must have leisure. A syllabus in which every minute is allocated to

definite work or duties is to be concerned. He will be a better student for devoting some of his time to non-medical interests. The Report draws attention to one notable omission from the nurture of the medical teacher. He receives no training in the art of pedagogy. And teachers are not often "born."

The Time-table

A quotation on the fly-leaf of the Report, from A. Castiglioni's *History of Medicine*, states that Galen estimated that eleven years was necessary to equip the physician with his necessary knowledge, whereas his contemporary and enemy Thessalus declared that six months' training would make an excellent physician. The proposed reorientation of the curriculum, with its emphasis on a rational understanding of the basic principles of medicine, will permit the ground to be covered in five and a half years, but it is recommended that there should be, before registration, a compulsory year of resident appointments, which should be adequately remunerated.

The premedical study of the basic sciences should occupy the first year, and the preclinical studies should cover one year and one term. After the preclinical examination a transition course of six months should be undertaken, followed by an examination in the principles of general pathology, this to take place in July of the third year. Then follow the clinical years. The time-table suggested by the Committee would complete all lectures and prescribed clinical work by the end of the first term of the sixth year, leaving one clear term free to the student for personal revision, unhampered by official classes, before the qualifying examination in March or April of that year. The plan would be as follows:

Year	Months	Stage
1 ..	Oct.-July Examination	Premedical
2 ..	Oct.-July	Preclinical
3 ..	Oct.-Dec. Examination	
3 ..	Jan.-July Examination	Transition
4 ..	Oct.-July	Clinical
5 ..	Oct.-July	
6 ..	Oct.-Dec.	Revision
6 ..	Jan.-March Examination	
6 ..	April-Sept.	Paid intern appointments
7 ..	Oct.-March	

The total number of lectures during the clinical period is 580, and a suggested allocation to the various subjects is given—100 to pathology and bacteriology, 90 to medicine, 70 to surgery, 50 to social medicine, and so on—but these allocations are no more than suggestions, put forward with no desire to dictate to the authorities of the medical schools. The student appointments to clerkships are summarized as follows:

Subject	Period
A. In-patient and out-patient:	
Medicine (including psychiatry) ..	6 months
Surgery (including orthopaedics and anaesthetics) ..	6 "
Obstetrics (in residence) ..	2 "
Gynaecology (to follow obstetrics) ..	1 month
Paediatrics (to follow gynaecology) ..	3 months
Casualty (in residence) ..	1 month
Pathology ..	1 "
B. Out-patient only:	
Ear, nose, and throat ..	24 hours (12 sessions)
Ophthalmology ..	24 "
Dermatology ..	24 "
Radiology ..	12 "
Veneral diseases ..	12 "
Physical medicine ..	12 "
Psychiatry ..	24 "
	6 out-patient and 6 extramural visits

A session is of two hours' duration except in radiology and physical medicine, where one and a half hours is regarded as adequate.

The Report also furnishes a preclinical time-table. It is suggested that four terms of twelve weeks be devoted to the preclinical period, together with a month of the summer vacation, this month to be devoted to completion of dissections, with radiological demonstrations of thorax and abdomen. A programme is given for lectures, practical work, and tutorial classes; the lectures in the first, second, and third terms to be 36 in anatomy and histology and a like number in physio-

logy and biochemistry, and in the fourth term 24 in anatomy and 36 in physiology, including in each subject clinical and applied, and 12 in psychology.

The Aim in View

The undergraduate curriculum, in the Committee's view, can do no more than lay the foundation of a doctor's education; but it should stimulate him to remain a student all his life. The curriculum can never be final; it is always moving, but never arrives. Strong disapproval is expressed of specific vocational trends in premedical school-teaching. Too often also current medical curricula are so subdivided as to lack continuity, and the student feels that each segment is an obstacle to be surmounted before the next is reached.

"The most frequently reiterated criticism of the curriculum which the Committee heard was that it conduced to the memorizing of a mass of detail without any appreciation of the underlying general principles, and that teaching was too often of the spoon-fed type instead of being aimed at the promotion of right habits of thought. The Committee believes that this criticism is often well founded."

The aim of medical education to be steadily kept in view is not to impart a mass of factual information in each branch of medicine, but to equip the student with sound basic principles, including the scientific outlook and method, a knowledge of the fundamentals of the medical sciences, competence in, and understanding of, certain indispensable techniques, and an intellectual resourcefulness and initiative in the handling of unusual and unexpected situations. The pressure of interested specialist groups to include more and more of their branches in the curriculum must be resisted. "Depth of understanding must not yield place to breadth of knowledge."

"The Committee does not, therefore, accept in its full implication the oft-reiterated view that the aim of the curriculum should be to produce a competent general practitioner. General practice is a special form of practice which must be founded on general basic principles and appropriate postgraduate study."

This leads on to the question of selection of students. The number of applicants far exceeds the places available for them in the schools. Even allowing for the post-war "bulge," the task of selection is formidable. Moreover, the field of recruitment is in future unlikely to be as restricted as in the past by social or economic barriers. The responsibility of selection should be in the hands of a small committee of the medical staff of the school, not thrust upon the dean alone.

The criteria to govern selection are intelligence, character, and interest in a medical career. As for intelligence, "what we need to achieve is a test which will reveal a native wit which is capable of forming habits of thought and not simply of absorbing knowledge." In assessing character, school reports and achievements in games will be of value. Interest in a medical career is difficult to assess with a candidate of immature age, but aptitude in scientific method may give some indication. Physical handicaps should not debar if they do not interfere with basic training: a man with an old infantile paralysis may well be accepted, whereas a man with severe deafness may be rejected until hearing-aids are more perfect. The conditions under which Government grants are given ensure that there is no unfair discrimination against women students, but marriage possibilities and consequent loss to the community cannot be ignored in assessing sex ratios.

The Threshold

In pre-university studies general cultural subjects, including science, should be taken. Factual knowledge of basic sciences will be extended during the first university year. The Committee wholly disagrees with the Goodenough Committee suggestion that a school-leaving examination at 18 might be accepted for the medical curriculum proper, and that the student coming from school with a good elementary grounding in general science need spend relatively little time on physics, chemistry, and biology in his medical course, such special training as is necessary being given as part of the teaching in anatomy and physiology. Such a view denotes a failure to recognize the fundamental importance of a thorough training in the methodology of science, which can best be inculcated in a special course in science at a university standard and in a university atmosphere.

Much of the disappointment which attends the existing first-year course is due to the fact that it is regarded as a Cinderella by the science departments in the universities, so that often indifferent and uninterested teachers are appointed to it. The subjects are taught, as Abraham Flexner said, "at distinctly a schoolboy level, and in a mechanical and humdrum rather than an imaginative and scientific spirit."

The first-year course should be lifted to an altogether higher plane. This basic training should be conducted by teachers of outstanding ability and qualifications, having adequate knowledge, a suitable personality, and a scientific spirit. One medical school has drawn on postgraduate research students to act as tutors, and the plan works excellently. In practical work, experiments should take the form of questioning and exploring practical phenomena, instead of the few stock experiments for which multiple sets of apparatus are provided.

It is suggested that instruction in the basic sciences might be advantageously developed from modern concepts of the atom as the starting-point. Physics, chemistry, and biology are not to be regarded as a mere introduction to the courses in anatomy and physiology. Ten lectures in the premedical course might be given on statistics—enough to enable the student to realize the danger of clinical impressions being overweighted by the striking episodes which remain fixed in the memory and to unmask the effects of propaganda which quotes only figures favourable to a thesis.

The Preclinical Period

The preclinical period—an unsatisfactory term—is an integral part of clinical study. The old distinction that anatomy is the study of structure and physiology the study of function cannot be rigidly maintained. In the living body anatomy and physiology are inseparable. Examples are given—the action of the voluntary muscles, the nervous system, etc.—of the difficulty of separating these two subdivisions of human biology.

The complaint is made that anatomy and physiology are taught in excessive detail. The aim in the preclinical period should be to give the student a synoptic view of the structure, functions, and processes of the human organism. The integration of anatomy, physiology, and psychology also is not a matter of co-ordinating syllabuses; it must be the continuing aim throughout the course. Teaching has suffered in some medical schools because these subjects have been entrusted to a research worker with little interest in or aptitude for teaching. Where the interests of the head of a department, preclinical or clinical, are mainly in research, a first-class teacher of senior status should be appointed on whom should rest the responsibility for departmental teaching.

The anatomy required is that of the living subject. The study of the cadaver is a means to an end, not an end in itself. It is suggested that, along with dissection, living anatomy classes should be formed—groups of students in charge of a teacher for the systematic identification, in the living subject, of the different structures. Dissection of the entire body is, nevertheless, essential, though there might be some reduction in topographical detail, and more use made of prepared dissected specimens. Dissection of thoracic and abdominal viscera must be performed with the aid of radiology. The anatomy of the nervous system should be taught more adequately. New textbooks of anatomy, not so encyclopaedic in detail as the old, are required.

In the physiology course the two reforms most urgently needed are (1) its correlation with anatomy and the preclinical and clinical subjects, and (2) reorientation of the syllabus with greater emphasis on human physiology and less on animal experiment. A list of topics to be covered in a syllabus is given, but it is the method of presentation and the balance of detail which determine the suitability of the course. There is no excuse for devoting to the chemistry of the nucleoproteins eighteen times the space given to visceral pain—the proportion found in one standard textbook on human physiology.

Excessive time is devoted in some schools to animal experimental physiology, leading the student to overestimate the importance of technical skill and to fail to appreciate that the purpose of animal experimental physiology is to help him acquire knowledge which cannot be gained by observation experiment on the human subject. The suggestion is made

that the students should work in pairs and carry out simple experiments on each other. A list is given of 37 experiments, on the blood, the cardiovascular, respiratory, and nervous systems, and the special senses, which could be carried out in this way. Errors of metabolism, deficiency diseases, disturbances of acid-base balance, and endocrine disorders offer an excellent opportunity for impressing on the student the links which bind the preclinical to his later clinical studies.

In a chapter on the teaching of normal psychology suggestions are made for taking the student from general principles to sufficient detail. The student should not be introduced at this stage to problems of abnormal behaviour. The ideal method of teaching psychology would be by seminar discussions rather than formal lectures, but there may be practical difficulties in the way. The least suitable person to teach psychology is the old-fashioned member of the medical staff of a mental hospital, whose experience is confined to abnormal psychology and almost entirely to the treatment of psychotic patients.

And So to the Patient

The purpose of an introductory course at the beginning of the clinical period is to lead the student by a smooth and unbroken transition from normal man to deviations from normal. He should be presented with a rational explanation of disease founded on anatomy, physiology, and pathology, with some instruction in history-taking and recording. The Committee suggests that two terms be devoted to the introductory course, and that at the end the student should be required to pass a professional examination in general pathology. At this point criticism is made of present-day textbooks, which often fail to provide a suitable and intelligent background for lectures. A graded series of textbooks, especially introductory ones, in the major clinical subjects is required.

In his clerkships in medicine, surgery, obstetrics and gynaecology, and paediatrics the student will be introduced to the responsible care of patients. He should be encouraged to regard himself as their doctor, becoming fully acquainted with them through his history-taking, and following every stage in their treatment and investigation. Study of in-patients should precede that of out-patients. There is no need for in-patient clerkships in the specialties.

The teaching of pathology should be spread over the whole of the clinical years, and the pathologists and clinical teachers should co-operate in the instruction given in lecture theatre, wards, laboratory, and post-mortem room. Altogether, including the introductory period, 200 hours should be assigned for lectures and demonstrations in pathology and bacteriology, and 80-100 hours' practical work. In the final year a month's clerkship in pathology will consolidate the student's knowledge. At present there is too great an emphasis on morbid anatomy and histology and on post-mortem findings at the expense of functional pathology and biopsy methods. Time should not be given to detailed discussion of the minutiae of pathology.

It is considered that pharmacology also should not be concluded in the early part of the clinical period, but the relation between pharmacological action and the use of drugs in disease should constantly be brought to the student's notice during the whole of his clinical studies. The course in materia medica, pharmacology, and therapeutics should cover about 140 hours. A few simple experiments, with drugs which will give the student useful assistance are listed. Part of the course should be devoted to systematic teaching of therapeutic methods—poulticing, blistering, dry-cupping and others. Many doctors enter practice unable to perform the simplest therapeutic procedures, such as the giving of an enema. Instruction in the proper writing of prescriptions will not be a waste of time. The practising doctor should be able to understand when he writes a prescription what he is asking his pharmacological colleague to do.

General Medicine and Surgery

General medicine is the linchpin of the clinical subjects. It should be taught as the basic clinical subject from which many specialties have branched off. The special purpose of the teaching is to inculcate a sense of the unity of medicine. The instructions, spread over the whole of the clinical years, should comprise systematic lectures, a junior and senior clerkship in the wards, constant attendance in out-patient departments and at

a minor ailments clinic, and a month's residence in a casualty department. The course of lectures should be planned by the professor, who might with advantage deliver most or all of them himself. Six months should be devoted to medical clerking and out-patients. In the wards three or four beds should be assigned to each student. A satisfactory medical teaching unit would comprise from 40 to 60 beds under a chief and assistant and provide for 10 clerks each term. At least two tutors should be on the staff of such a unit, to ensure that individual tuition is given. The student should be made familiar with the recognition of common infectious fevers treated in isolation hospitals, and arrangements should be made during the second and third clinical years for attendance at these hospitals as clinical material becomes available.

The need for the student to study chronic disease demands greater emphasis. In his third clinical year a few patients suffering from various forms of chronic disease might be allocated to him.

A preliminary course in the principles of surgery will have been given during the transition period. The clinical period should include two dressing appointments of three months each, a junior one in the first year and a senior one after medical clerking is completed, a series of systematic lectures covering two years, and ample opportunities for work in the out-patient and casualty departments. The first clinical appointment should be devoted to in-patient dressing, the second primarily to out-patient work. At least part of the second appointment should be resident, so that experience of acute abdominal emergencies may be obtained. In general the student should be expected to attend only operations on his own patients. For the purpose of undergraduate education orthopaedic and traumatic surgery should not be wholly divorced from general surgery. Work in the fractures clinic should be included in the second surgical appointment; a particular case should be followed continuously from admission to discharge. Instruction in orthopaedic conditions should include the principles and methods of rehabilitation. Arrangements should be made for the student to see something of other branches of surgery usually undertaken by specialists, such as thoracic, plastic, and neurological surgery. Lectures and discussions on common diagnostic problems (lumps under the sterno-mastoid, acute pain in the right iliac fossa, a limp in a child) should be introduced into the systematic course and dealt with in clinical lectures.

The scope and principles of anaesthesia must be learned, with the ability to administer simple anaesthetics for minor operations. Teaching should not be more detailed than the general practitioner is likely to require in his ordinary practice. More advanced and complicated techniques should be left for postgraduate study. Six lectures in anaesthesia may be given, with experience in practical work. The student should be assigned to an anaesthetist during his surgical clerkship, when he may probably have the opportunity of administering 20 or 30 anaesthetics.

Obstetrics and Gynaecology: Paediatrics

Under the present Medical Acts a basic training in midwifery must be undergone by all medical students. The curriculum should provide as high a standard of training as will enable the practitioner to fulfil the requirements of the Acts without having a special postgraduate diploma.

The main direction of improvement should be to take into fuller account the needs and resources of the family doctor and to devote less of the student's time to the study of the rarer, if more interesting, cases that come into hospital for specialist attention.

It is recommended that the course in obstetrics and gynaecology should be taken after the student has spent six months in medical clerking and six months in surgical dressing. The instruction should include 30 or 40 systematic lectures in obstetrics and 15 in gynaecology. Each case should be allotted to a student on attendance at the hospital, and attendance on a patient in labour should always have precedence over lectures or other duties. Efforts should be made to allow the student to deliver at least 20 normal cases. He should, when possible, also carry out at least one low-forceps delivery and one breech delivery in a multipara, and should have practice in the repair of perineal tears and in episiotomy incision. In the arrange-

ment of a teaching hospital adequate residential accommodation for students should be provided having easy access to the labour wards.

A series of 15 systematic lectures should be sufficient for theoretical instruction in gynaecology, and the main object of the clinical instruction in that subject should be to teach the student to make a pelvic examination with sufficient skill to recognize and interpret obvious and gross departures from the normal.

Paediatrics, "one of the most important subjects of the medical curriculum," should be studied after the course in obstetrics and gynaecology has been completed. The student would then come to it with adequate preparatory knowledge, having received instruction in antenatal care. He should spend three months as a paediatric clerk, having direct responsibility for at least four beds. One of the months should be spent in residence at a children's hospital or department. He should make himself familiar with the child welfare and other orthopaedic services of the health authorities. He should visit school medical, tuberculosis, and child-guidance clinics, and a mental deficiency institution. It is suggested that six lecture-demonstrations and discussions should be given in the third term of the first clinical year and 18 during the later period of clinical studies. They should be confined to the common diseases of childhood.

Psychiatry: Social Medicine: Public Health

For psychiatry no set departmental course to be taken at a particular stage of the training is proposed, but a curriculum which pervades the whole clinical period. Various studies are mentioned which might be interwoven in the transition and clinical periods so as to give a more coherent and intelligible idea of the mental aspect of medicine than is given at present. One of the defects of present-day teaching in psychiatry is that too much is left to registrars and teachers of similar status. The introductory course should include a series of 12 lectures on the general principles of psychopathology. Two further series, each of 12 lectures, should be arranged in the first and second clinical years respectively. Some of the time of the lectures might be devoted to discussions of the Socratic type concerning difficulties encountered by the student in his reading or clinical experience. It is not necessary to take an in-patient clerkship specifically in psychiatry; both the psychiatric and the physical aspects of disease should be included in the medical clerkship. Out-patient work and case-taking form an important part of psychiatric training, but these should not begin until after completion of medical clerking and surgical dressing in the second clinical year. Six attendances at psychiatric out-patient clinics are recommended. Some time should be devoted, with the co-operation of the paediatrician, to children's sessions. Extramural visits should include institutions for mental defectives, the observation ward of a psychiatric department or mental hospital, and a mental hospital itself. A special professional examination in psychiatry is not favoured; one or two questions in the papers on medicine should be primarily psychiatric in scope.

Instruction in the preventive aspect of disease should be given, by emphasis, by all teachers throughout the clinical period. Students should be encouraged to regard the patient and his environment as a whole. Every hospital ward will contain some patients who will serve as suitable tests for the discussion of the interrelationship of disease and social circumstances.

In the systematic course the following headings are suggested:

Transition Period.—History and social causes of disease; nutritional requirements of a working population; psychological reaction of patient to environment.

Second Clinical Year: First and Second Terms.—Natural history of tuberculosis; social pathology of rheumatic fever; venereal disease as a social problem; maternal and infant mortality, etc.

Second Clinical Year: Third Term.—Progress of public health; epidemiology of diphtheria, etc.; public health bacteriology; environmental health services.

During the second clinical year also the functions of the school medical service might be taken with paediatrics and psychiatry. Industrial diseases and medical supervision in factories might be taken during the same year as field work at different times. The appointment of a professor of social medicine will not be practicable at every medical school, but

there should always be a member of the staff available and competent to organize the teaching of the subject.

Industrial medicine should be taught as a special aspect of social medicine, not as an independent subject. A systematic course of lectures might deal with the following: history of industry; occupational disease and mortality; the Factories Acts as a contribution to a positive health programme; practice of medicine in industry; rehabilitation and resettlement. Here again a separate examination is not recommended. Examiners in general medicine should expect the student throughout his answers to have regard to social, occupational, and economic factors in illness.

A brief chapter on forensic medicine discusses the bearing of medico-legal problems on the medical practitioner. Here again at present too much attention is given to details which should be the province of the expert. "It is unnecessary to burden the undergraduate student with detailed instructions in the conduct of such post-mortem examinations as may be required by a coroner." Toxicology should be taught from the clinical point of view. It is not considered necessary for the toxicologist to have charge of beds for teaching. The most suitable time to present forensic medicine is in the summer preceding the final year. Practical teaching should be supported by systematic lectures occupying about 20 hours. Two lectures on medical ethics and the legal responsibilities and duties of the general practitioner should be included.

Specialties

These, in view of what has already been stated, are treated very briefly.

Ophthalmology.—Criticism by those in charge of eye departments in large hospitals arise from cases which exemplify (1) failure to diagnose intraocular disease and delay in referring cases to specialist; (2) attempts to treat serious eye diseases before so referring; and (3) failure to assess correctly the value of ophthalmic examination as an aid to diagnosis. The inference is that many practitioners have not received an adequate basic teaching. The aim should be to give a thorough grounding in "anatomical diagnosis" without necessarily attempting "pathological diagnosis." A clinical class should not exceed five students. (24 lectures.)

Ear, Nose, and Throat.—Technical skill in use of nasal speculum, laryngoscope, and otoscope, and the simple clinical methods of examination and treatment, should form part of the equipment of every general practitioner. The student might attend out-patients during his second clinical year. (24 lectures.)

Dermatology.—In the transition course six to eight lecture-demonstrations on clinical examination of dermatological cases should be included, and instruction in clinical dermatology given in the second and third clinical years, organized as a curriculum rather than a set course. Later in the second year he should study skin cases in wards and the out-patient department. (24 lectures.)

Veneral Diseases.—Twelve attendances at the V.D. clinic for lectures, demonstrations, and practical work should suffice to cover the ground for the undergraduate. (6 lectures.)

Physical Medicine.—A list of topics to be covered in an elementary fashion is given. The course should not include general discussions on osteoarthritis, fibrositis, or gout; these are rightly in the domain of general medicine. (8 lectures.)

Radiology.—A special course for teaching scope and methods. It is unnecessary to learn special techniques. Conferences and discussions on selected cases between consultant, radiologist, pathologist, and any interested specialist are valuable methods of teaching. (9 lectures on radiodiagnosis, 3 on radiotherapy.)

Examinations

The Committee rejects the view that examinations are unnecessary and undesirable for the medical student; well-designed and well-conducted examinations are an essential part of the machinery of education. It favours the internal method, but with an associated external examiner. The final examination should be devised as a whole, without separate papers in the specialties. After the examination in general medicine at the end of the transition course—that is, in the first year of the student's third year—he should not be required to undergo any further examination until he has completed the

full curriculum, thus leaving him two and a half years, unhindered by the examination burden, to absorb the principles and ideals of medicine as a single integrated study. The final examination may, for practical convenience, be divided into the three main subjects, but the parts must not be regarded as separate obstacles to be surmounted one at a time.

A special committee of internal examiners in all subjects should undertake the general organization, review the proposed questions, decide the standards for the allocation of marks, and afterwards review the results. The paper on general medicine should be the responsibility of the professor of medicine; there should be no papers in the specialties, but some questions should be devised which the candidate will be unable to answer satisfactorily without an adequate knowledge of one or more specialties (e.g., "A man of 60 wakes in the morning with a right frontal headache. Discuss the differential diagnosis"). The clinical examination should take place in hospital rather than in an examination hall in order to give a wider choice of cases. A healthy person might be assigned to a candidate in the clinical examination, but the candidate should be forewarned of that possibility. The following precepts for examiners were formulated by one witness, and the Committee endorses the advice and underlines the fourth precept:

- (1) Treat the candidate with the courtesy which is his due.
- (2) Do not flatly contradict any candidate.
- (3) Try to find out what the candidate really knows. If you discover a serious lacuna there is no need to plumb it to its depth.
- (4) Be prepared to receive views with which you may not agree so long as they are accepted by teachers of repute.
- (5) Put your questions clearly.
- (6) Be careful how you joke with examinees.

The Intern Year

The idea of including a period of clinical experience under supervision as an integral part of the training of medical students was first put forward by the B.M.A. Committee in 1934. The Goodenough Committee elaborated the proposal, to which effect has been given in the draft Medical Bill submitted by the General Medical Council to the Minister of Health. On the ground that they all belong to the compartmental system, against which the whole Report is directed, the present Committee objects to various forms of internship suggested, including the Goodenough recommendation of one appointment for six months in general medicine and another of like period in general surgery. The intern year should complete the student's basic training by introducing him to the responsible care and treatment of patients, with a gradual increase in personal responsibility. The intern should be assigned both in-patients and out-patients as they are admitted to hospital.

"The intern will thus receive the patient as a sick person, and not as a 'medical' or 'surgical' case, and at least six months will be devoted to this integrated study of patients and not be divided into 'medical' and 'surgical' appointments. Such labelling prematurely attunes the student's mind to a particular diagnosis."

Each patient admitted to hospital would be assigned to an intern, who would be responsible for writing the history and for the minor laboratory examinations and technical procedures, would be present at all consultations, would glean the social background, note the progress of the patient, and undertake the follow-up. He would really act as the personal doctor of the patient and be even closer to him than the attending physician or surgeon.

It is estimated that an approved hospital should be able to take one intern for every 20 to 25 beds, and that it should not be necessary for any one hospital of 250 beds to have more than 10 interns at a time. This means that, with an annual admission list of 6,000 patients staying on the average two weeks, each intern would have 10 new patients a week for study. The student should be paid an adequate salary during his internship. At the end of his intern year he should not have to undergo an examination, but for the purpose of admission to the Register an officer of the approved hospital should be required to certify, through the qualifying body, that the student has satisfactorily completed his intern appointment.

The final recommendation of the Committee may ultimately prove to be the most fruitful—that there should be an Association of Teachers in Medical Schools to keep in continual discussion the various experiments in medical education and to plan an assault on the many problems yet unsolved.

MEDICAL ART SOCIETY EXHIBITION

[FROM A SPECIAL CORRESPONDENT]

Is there such a thing as an "amateur artist"? There are public figures like Mr. Churchill, and busy professional men like Sir John Parkinson and Sir Philip Manson-Bahr, who manage in some inexplicable way to find time to paint, and to paint as competently as any professional. But there cannot be two standards for art, and it would be sheer condescension to judge the medical artists now exhibiting at the Walker's Galleries, 18, New Bond Street, by any artificially lowered standard.

It is pleasant to see that so many well-known and busy members of an overworked profession have time to bring out their easels to such good effect. For example, besides Sir John Parkinson and Sir Philip Manson-Bahr, the list of artists includes such names as Dr. H. S. Stannus, Dr. Geoffrey Bourne, Dr. W. S. C. Copeman, and Mr. Holmes Sellors.

On the whole the tendency is towards the orthodox and academic, but this is to be expected. There are, for example, some extremely competent etchings by Dr. E. Goodwin Rawlinson and Dr. E. Puddy. The best of the more traditional water colours, because the least fussy, is Dr. Charles R. Porter's "River Congo, Rainy Season," although Sir John Parkinson's "Glacier Stream" is architectural in its treatment of a mountain set against a flat foreground, and Dr. Henry Wilson's "Scarborough Bay" has a quiet sense of colour. Dr. Dorothy Fare's studies of trees are observant, though perhaps Dr. L. E. Houghton's "November" has a more sensitive feeling for atmosphere. Mr. R. W. Payne has a pleasant style of his own; his drawing is meticulously childlike, and he uses bright, flat colours with pleasing effect. Sir Henry Bashford has contributed two extremely interesting studies in grey wash: "Rock Pool" is a highly original and effective design, and more successful than "March Study—Hampstead."

The best of the water colours, however, are Dr. C. J. Dudley-Dunn's "Village Roofs," and, more particularly, a charming and naive painting by Dr. J. D. W. Pearce called "Positano." I should be surprised if the unaffected colouring and drawing in this little scene of houses grouped on a hill were derived from any "cult of the primitive"—it looks spontaneous and genuine.

The oil paintings show more evidence of lack of leisure and skill, although there are some good things among them. For example, three charming paintings by Dr. Helena Wright are spoilt by a certain muddiness ("Bathing Beach, Taormina," with its scattered sunshine, is the best). Dr. Margaret Little's "Mynydd Bach," a study of red- and blue-roofed cottages against green hills, is not quite successful for the same reason. Dr. Edith Magill's painting of a scene near Stockbridge is more successful because it is less ambitious, and her colours are better controlled. Dr. Christopher Keating shows good plastic sense, especially in the sturdy treatment of the white cottage in the foreground of "The Canal." Dr. Norman Patterson has treated "Springtime in My Garden" extremely felicitously. The most interesting oil painting is Dr. Lorna King's "Landscape." It is reminiscent of some of Banting's paintings (which the writer has seen in reproduction only). The colours are subtle, the plastic sense and design well developed, and the whole painting looks as if it has been really seen, and not painted through the eyes of somebody else.

Among the oil paintings are the two worst pictures in the exhibition, Mr. Geoffrey Parker's "Nightmare" and Dr. C. M. Ruben's "The Paths of Glory lead but to the Grave." These two symbolical paintings are not relieved even by good draughtsmanship.

The few items of sculpture are competent. The most interesting is a plaster-of-Paris cast of "A Doctor's Face" by Dr. S. Hales. It looks as if it might have been a mask made direct on the model, and it suffers from a lack of artistic form; but the expression is interesting.

The exhibition contains a succinct commentary on the present medico-political situation. Dr. E. Puddy's "Quo Vadis?" shows a doctor sitting at a desk crammed with sheaves of official papers and regulations, among which can be seen the familiar panel cards; in front of him a poor, stooping patient, cap in hand, waits pathetically, and behind the patient stands Christ with outstretched hands.

Preparations and Appliances

A PORTABLE ANAESTHETIC APPARATUS

Dr. G. E. HALE ENDERBY, Anaesthetist, Royal National Orthopaedic Hospital, writes: This apparatus has been designed to meet the need of a compact reasonably portable machine providing facilities for the administration of most anaesthetic agents. There are two main sections of the apparatus. One is the flowmeter-cylinder unit carrying oxygen (15 gal.), nitrous oxide (50 gal.), and cyclopropane. The other is the circle-type absorber, which is a Waters canister fitted with a specially designed head incorporating directional valves. This enables the use of twin tubes, and the canister can be fixed in any position in relation to the patient. It is usually attached beneath the operating table by a screw clamp as described by James (*Journal*, 1947, 2, 345). The directional valves (rubber flaps) are mounted in detachable angle-pieces carried on the ends of the corrugated tubes. This facilitates washing and sterilization if necessary. The absorber unit can be replaced by a continuous-flow Magill rebreathing attachment for use with nitrous oxide, oxygen, trichlorethylene, and ether if desired. The trichlor-

ethylene is used in an M. and I.E. bottle, and the ether in a Magill drip. Both these are carried as accessories for attachment to the flowmeter unit, and are not permanent features of the machine. No direct provision is made for the use of carbon dioxide. A supply is carried in a C-type sparklet bulb with an attachment which fits the cyclopropane yoke. This is inserted in place of the cyclopropane cylinder when required. Mounts on the baseboard carry the Waters canister and a face mask when not in use. The whole apparatus fits into a carrying-case having a central compartment for the apparatus and narrow compartments at each end for hoses, rubber tubing, etc. The central section is fitted with a shallow tray for accessories.

My thanks are due to the skill and patience of Mr. Childerhouse and staff of Medical and Industrial Equipment, Ltd., New Cavendish Street, London, W.1, who made this apparatus for me; and to Miss Farmer, medical artist, Rooksdown House, Basingstoke.

Reports of Societies

ELECTRO-NARCOSIS

In the Section of Psychiatry of the Royal Society of Medicine on May 11 a discussion took place on electro-narcosis.

Dr. SPENCER PATERSON, who showed a film of the treatment being given to patients in the Psychiatric Unit of the West London Hospital, said that about two years ago, in different countries and in different hospitals in the same country, there were being passed through the brains of patients electric currents which differed from each other in every particular; there had been little experimental work to show which were safe and which were dangerous. There were many psychiatric conditions which failed to improve when the patient was given only two or three applications a week, but it had been discovered that the more intense administration of electric shock could effect recovery in otherwise intractable cases. The side effects were not serious, but careful nursing was often necessary. It was therefore sought to obtain a better therapeutic effect with little or no discomfort to the patient, and to this end the passing of a low current through the brain of animals for a period of several minutes was studied.

The main difference between the electro-narcosis machine and the electro-shock machine was that with the former the current was kept automatically regulated. Instead of the sudden agitation of the brain cells, a more gentle application was obtained by allowing the current to rise to its maximum over a period of 3 seconds. Curare was also used in advance of the electrical application and had the effect of diminishing the violent movements of the patient. Electro-narcosis was generally given three times a week for about eighteen times. Sometimes if the patient was quite well after ten or twelve applications the treatment was stopped, but there was less likely to be a recurrence if it was given for a greater number of times. If the patient showed undue memory disturbance it could be given only twice a week. With a colleague he had given altogether 719 treatments, from 9 to 20 for each patient.

The previous history of every patient was elicited. If he was sufficiently robust to tolerate electro-shock it was likely that he would be able to have electro-narcosis, especially with curare. One generally had to wait 3½ minutes between the curarization and the onset of electrical treatment in order that the drug might take effect. An electrocardiogram was always taken before treatment. The chief complications were due to saliva and mucus and might be prevented by atropine 1/6 gr. (11 mg.). Sometimes whiteropy mucus collected in the back of the throat. He had heard of cases of lung abscess following electro-shock. Sometimes the patient complained that he had become conscious during the treatment. This experience might be very frightening; the patient might feel suffocated and also see bright flashes of light or hear loud noises.

Except for small and young patients it was rare to give an application of less than 200 mA. for the last 30 seconds. The blood pressure should be taken several times during the treatment of a patient. A pressure which had been normal at first might rise as high as 260/160 mm. Hg. Sodium amytal was more likely to keep down the blood pressure than pentothal, but it had the disadvantage of taking a little longer to act. Occasionally the following symptoms occurred temporarily after treatment—headache, lassitude, and a sense of constriction around the chest. There might be some amnesia. Often, however, the patient experienced no discomfort whatever.

Up to three months ago 35 schizophrenics had been treated with electro-narcosis in his unit. The cases fell into three groups. There were 9 cases in which there had been a previous schizophrenic episode, from which they had recovered, and after electro-narcosis for this later attack 8 of these patients were back at work within three months and only one was not improved. The second group consisted of 10 patients who had been ill for less than twelve months since they were first seen, and of these 9 returned to work. The third group consisted of 16 patients who had been ill for more than a year when first seen, their average duration of illness being 3.2 years, and of these 4 made a complete recovery, 3 more were able to return to work, and the other 9 were greatly improved.

Comparing the results of electro-narcosis with those of shock, Dr. Paterson said that the effect of electro-narcosis in cases of schizophrenia was comparable with that of an initial course of electro-shock, but he believed that electro-narcosis produced a better result whilst at the same time causing less physical strain. He had treated 14 cases of schizophrenia with electro-narcosis after electro-shock had failed; in 9 of these the response was more favourable with electro-narcosis, and in 6 of them electro-narcosis brought about recovery. But it was likely that the previous electro-shock had helped the electro-narcosis, as there was perhaps a synergic action between the two. Electro-narcosis was in one respect safer than insulin coma therapy, for if the patient appeared to have undue cardiac or respiratory difficulty the current could be switched off at once, whereas with insulin coma it was more difficult to stop the effect.

In 16 cases of depression treated with electro-narcosis showed complete recovery. In 8 cases of severe psychoneurosis there were two striking recoveries. It was important to treat these patients as soon as the morbid state was manifest—a far better borne out by the larger proportion of successes with the electro-narcosis than with the insulin coma therapy. Among the hundreds of cases treated, no patient had complained of being worse after treatment. He believed that electro-narcosis and kindred treatments were only at their beginning. Full investigations were being carried out at the West London Hospital and elsewhere, including psychological tests before and after treatment.

Results in Schizophrenia

Dr. W. L. MILLIGAN described the treatment by electro-narcosis of 120 patients at St. James's Hospital, Portsmouth. These included 70 cases of schizophrenia, 15 of acute schizophreniform reaction, 10 of periphenia, 10 of melancholia, and 15 of psychoneurosis. If the treatment was carried out properly the patient did not recall any unpleasant sensations. Approximately 2,500 treatments had been given, and, except in the periphenic group, no patient had refused to continue. Many impartial observers had commented on the cheerful and composed manner of patients awaiting perhaps their twentieth treatment. Especially in cases of schizophrenia it was essential to give at least 30 treatments before assuming that the therapy was not producing the desired results.

Of the 70 schizophrenics treated 44% showed complete remission and a further 17% showed social recovery. Only 14% were not improved. If children, with whom the treatment was almost invariably unsatisfactory, were omitted from the group the percentage of remissions among the 60 adolescents and adults was 52% and of social recoveries 20%. The duration of illness was an important factor; all the 7 schizophrenics with a history of under one year recovered completely, as did 15 of the 17 whose illness had lasted between one and two years. He agreed that the duration of follow-up had not been sufficient, but in no case had it been less than three months, and 40 cases had been followed up for between a year and twenty months. Atypical schizophrenics responded well, and good results were obtained with the 10 melancholics. Electro-narcosis was a much smoother form of treatment than electro-shock, and one had more confidence in applying it, especially to the elderly patient. The modified method consisted, in the first stage of electro-narcosis, of raising the current from zero to 180 mA. in roughly two seconds; after remaining at that height for 30 seconds it was very slowly brought down. The idea was to cut out all evidence, if possible, of the clonic stage. Convulsion was modified to such an extent as to be no longer noticeable. He thought it could be reasonably claimed that electro-narcosis formed a useful addition to their armamentarium.

Curarization of the Patient

Dr. GERALD CAPLAN reported on a modification in the technique of electro-narcosis which he had worked out recently with the help of the anaesthetist, Dr. Samuel Carden. The apparatus which he had designed was similar to that used by Dr. Spencer Paterson and Dr. Milligan. It was a small, light-weight apparatus weighing 8.6 kg. and incorporated a non-thermionic current stabilizer. A special feature was the inclusion of a voltmeter which allowed a continual check to be kept on the resistance

the external circuit. If the electrode resistance increased suddenly owing to inadequate contact with the skin of the patient this would be immediately shown by an increase in the stage output. This was an important safety device to prevent skin burns. The modification in technique worked out with this apparatus was designed to ensure satisfactory oxygenation of the patient throughout the course of electro-narcosis. In the later stages of electro-narcosis, which manifested itself as spasm of the glottis, which manifested itself as the inspiratory stridor. This was considerably reduced by partial curarization of the patient. Three minutes before electro-narcosis was started the anaesthetist gave an intravenous injection of pentothal sodium 0.3 to 0.4 g., plus atropine 1.60 gr. (1 mg.) and d-tubocurarine 12 to 15 mg. Immediately afterwards he began the administration of pure oxygen and continued this throughout the treatment. The amount of curare given was not sufficient to prevent the muscular movements which were an important sign of the depth of the electro-narcosis, but damped down any convulsive or preconvulsive movements which might produce fractures and also caused sufficient relaxation of the vocal cords to allow of adequate oxygenation. Occasionally, when the initial current dosage was not correctly estimated, there was a delay in the reappearance of the patient's spontaneous respiration. With this technique this did not cause anxiety, as the patient could be kept pink by respiration with oxygen by means of intermittent manual compression of an ordinary anaesthetic bag. On several occasions the patient had been kept in a satisfactory state of oxygenation despite the fact that he did not breathe spontaneously throughout the whole seven minutes of his electro-narcosis. In addition the pentothal injection removed any apprehension due to the curarization, and was also a sufficient safeguard against the troublesome complication of an inadequate electro-narcosis, for which the patient preserved a partial memory.

Mr. GREY WALTER said that the literature of electro-narcosis was immense and bewildering. About eight years ago they were anxious to determine the margin between the maximum therapeutic dose and the minimum lethal dose of current, and involved an experiment similar to those described by the speaker. The experiment was interesting, and it seemed to those concerned as if they were watching the cerebral activity under a large stimulus from outside. He was rather bewildered by the term "electro-narcosis" as descriptive of the procedure outlined in that discussion; he would have thought the term "electro-delirium" more suitable.

ENDAUERAL TEMPORAL BONE SURGERY

DR. LEMPERT'S LECTURE

Dr. JULIUS LEMPERT, of New York, delivered a lecture at the Institute of Laryngology and Otology, London, on May 8 on "Endaural Temporal Bone Surgery and the Philosophy of its Evolution." The lecture held the interest of a crowded assembly for two hours, and Dr. Lempert was given an ovation at the close.

Thirty years ago, said Dr. Lempert, when he began the practice of otology, he was not satisfied with the results he obtained in temporal bone surgery. One of the problems was obstructive exostosis of the external auditory canal. The accepted procedure was to do a mastoidectomy, breaking down the posterior wall of the canal, a method which destroyed far too much healthy tissue and sometimes resulted in intracranial complications. He set about finding a way of doing this operation without destroying the mastoid process, and that was the beginning of his endaural surgery. He demonstrated his method of making an incision and lifting slowly, a few millimetres at a time, the skin and periosteum from its attachment to the bony surface. Then, with a small electrically driven burr, he removed as much of the exostosis from the posterior wall as possible, and continued to elevate the skin and periosteum until he reached the tympanic ring, gradually removing the mass wherever found, and so down to the anterior mastoid cortex, without opening any of the mastoid cells. This was a most satisfactory procedure both for otologist and patient; it could be carried out under local or general anaesthesia, and the stay in hospital need not be more than one day.

Mastoidal Tympanectomy

Another problem of those early days was post-auricular fistula, and in treating this it seemed inevitable that another deformity should be created. He tackled this also endaurally, along the anterior margin down to the bone through skin and periosteum, and again with a periosteal elevator slowly raising the auricle in a posterior direction. He everted the funnel of the auricle in a posterior direction and immediately had more tissue than he needed to correct the post-auricular fistula. The excess skin and periosteum, together with any infection within the region, was removed with the curette; one or two sutures with drainage completed the procedure, and at the end of about 10 days there was a perfectly healed area.

Why did fistula follow surgery of the temporal bone? radical mastoidectomy could not be done through a post-auricular incision, and therefore it was necessary to go to the auricle, and destroy the external auditory canal. There was necessary destruction of tissue, undermining the whole foundation of the auricle, and as a result post-auricular fistula occurred. Dr. Lempert described his method of performing what he called mastoidal tympanectomy. The method was based on the principle of exposing the antrum to direct view. "Anything you can see, you will not hurt, but you must be able to see it." Instead of approaching the antrum from within the ear, he worked from within outward, with no danger of infection. He worked from within outward, with no danger of infection, obtaining a proper exposure of the antrum and removing the pathological process within the middle ear.

If the structures involved were not to be injured, proper lighting was necessary. The otologist must get out of the patient of using the ceiling light in performing temporal bone surgery; an electric head-light must be employed. A magnifying glass should be worn for two reasons, firstly because the disease process could not be removed completely unless the field were enlarged two or two and a half times to enable the surgeon to see what he was doing, and secondly, because "you will see for the first time how beautiful the antrum is."

The removal of granulations or polypi from the middle ear was not sufficient to stop a chronic discharge. For twenty years there might have been an infection in the middle ear, with the result that the lining membrane was infected. The perieustachian tube cells which are infected must be removed, but a curette must never be introduced into the eustachian tube itself, for this was likely to result in osteomyelitis of the bony portion of the tube. Dr. Lempert indicated in great detail with a series of lantern slides every aspect of this procedure, and said that if this course were followed the chances of getting a dry ear were 100%, "provided you do not delegate the after-treatment to some young intern."

Accidents at Operation

When an otologist injured the facial nerve while doing a radical mastoidectomy and did not know it, but had to be told by his anaesthetist, "The face is crooked," he should not be doing temporal bone surgery, because he did not know where he was in the temporal bone. Accidents happened to anybody but the skillful surgeon would tell the anaesthetist long before the anaesthetist told him. He will say, "Will you look at that face? I have just injured the facial nerve."

The most usual facial nerve injury was caused by the fracture inwards of a little piece of bone into the fallopian canal, compressing the nerve. This could be readily observed, and it took less than a minute to remove it. When the facial nerve was torn and a piece was missing it was another story. Here he demonstrated how he removed the facial nerve from its canal, converting the curved line into a straight line, and suturing the nerve end to end.

Endaural Simple Mastoidectomy

Years ago, when many simple mastoidectomies were done for acute suppuration one of the problems was that, after operating successfully on a small child, the child would turn up six months or a year later with a ballooned-out post-auricular scar. This was an inflammation of the scar which required incision and drainage, and that was all. But if instead of

going to the surgeon who had performed the original operation the child was taken to a colleague, the case was liable to be pronounced one of recurrent mastoiditis. When a middle ear infection occurred in a healthy bone that had never been operated upon the course of least resistance for the infection was the tympanic membrane; this might go on to rupture or it might be seen in time by an otologist and incised and drained. But when the child once had a mastoidectomy performed and, following it, had a middle ear infection, the course of least resistance was no longer the tympanic membrane but backwards to the mastoid wound, the resistance of scar tissue being much less than that of healthy tissue.

It then occurred to him that if he performed his simple mastoidectomy endaurally it might be impossible for this to happen, because there would not be a post-auricular incision, and the inflamed scar ballooning out would no longer be seen. He had now been performing endaural simple mastoidectomy for many years. The incisions were the same as in his fenestration operation. They looked very simple, but to make them correctly so that there was proper exposure of the temporal bone required some experience. The first incision should be a straight line outwards, starting from within and coming out. Then, when the retractors were pulled, an exposure was obtained more adequate than that by the post-auricular route. In making this incision a speculum should be used and the soft parts stretched.

Dr. Lempert illustrated various other procedures, and his lecture was greatly appreciated by a large audience of British otologists.

co-ordinating body. We have elected a Council; we have given them certain limited powers; let us cheerfully accept the decision however much we may feel disgruntled, so that we may go on with their difficult task in the knowledge that the medical profession is solidly behind them.—I am, etc.,

Salford, Lancs.

STANLEY HODGSON.

Goodwill

SIR.—May one who some months ago was accorded a courtesy of your columns in an attempt to offer some reasonable arguments in the present discussion about the National Health Service again request the same courtesy? One would have thought that many practitioners had by now reached the conclusions advanced by Dr. Alfred Cox (May 15, p. 949), with the necessity of his lucid and convincing survey, were it not for such letters as those you publish immediately afterwards as later in your correspondence columns.

Dr. Cox gives three good reasons against basing refusal to work the Service on forfeiture of goodwill, and is amazed to find many of us do not think this worth fighting for. If it were possible to find a general practitioner who had not been up to the war, his experience if he came into practice at any time later than 1918 would probably be that he had to borrow the whole cost of his practice and take ten or fifteen years repaying the loan and finding interest amounting to a considerable sum which expense he would have avoided had he been in possession of capital at the start; that during these years he acquired a family whose education involved him in some form of further loan charged, actually and in the last resort, on his practice; that as they grew up he found it expedient to buy his house and, although that was done on a mortgage, it was the practice again which paid for it; and that between twenty and thirty years after he acquired goodwill he possessed it free from charges for loans of any kind. For the rest of his working life he really owns goodwill, which perhaps increases in monetary value through his efforts and certainly does so because the value of money is falling. And when he dies or retires his success goes through the same cycle with a larger sum in pounds sterling to pay off on all three probable items.

I am one of those, no doubt numerous, practitioners who for every reason to be grateful to the businesses who have advanced money to buy practices; but no informed person can view with equanimity the prospect that every time a practice changes hands it is probably charged with a debt increasingly large in terms of money or deny that continuation of this process will inevitably end in the general practitioners of the country being in debt the whole of their working lives. Personally, that there might be a case for breaking this vicious circle first occurred to me when it was authoritatively stated, about the time the N.H.S. Bill was first adumbrated, that insurance companies and banks had an interest in about a third of the practices existent. With knowledge that the loans are ordinarily for ten or fifteen years it was easy to work out that it indicated practically all of the practices in the country which had been sold within the last ten or fifteen years, since a man may stay in a practice no more than 30 years and is hardly likely to do more than 45.

There may have been a time when parents were able to buy the then considerably smaller cost of medical education for a short term of years than at present, and afterwards find the money to buy practices for their sons. If it ever existed that time is past; and although private business enterprise has well served both the profession and the community since it ended, such a financial foundation for a profession on which the health of the nation depends is not only theoretically objectionable but within sight of becoming practically impossible. It is rather rough on a young doctor, perhaps even rougher on a mature one whose youthful years have been passed in, say, the Arakan, to put him in a position where he has to choose between buying drugs for his patients, rebuying a car necessary for their service, or repaying the instalment of capital due to the lender.

Without a complete alteration of economic tendencies, of which there is no prospect, legislative interference in the interest of the nation as a whole was sooner or later inevitable; and Parliament has decided in favour of acquisition of capital values which are known fact very largely do not inhere in the corpus of general practitioners against the alternative of State-guaranteed loans for purchase. With the continual rise in monetary value of practices and the almost universal insistence by vendors on tacking a house (for which more is asked than for the practice) on to the goodwill, no responsible Department could have recommended, and no responsible House of Commons of any political complexion could have sanctioned, the only practicable alternative.

Correspondence

Accommodation for Annual Meeting, Cambridge, 1948

SIR.—The Cambridgeshire and Huntingdonshire Branch of the Association is looking forward to the honour of holding the first Annual Meeting following upon the war. The organization for this Meeting has been a formidable problem, particularly in the matters of accommodation, feeding, and transport. It is very important for us to have a rough estimate of the numbers likely to attend, as soon as possible, in order that firm bookings may be made.

So far the response to the notices which have appeared in the *Journal* has been disappointingly small. We believe that this is due to the fact that very many members have not realized the importance of making early application.

I should be glad, therefore, if you would bring this point to the notice of all members of the Association.—I am, etc.,

LIONEL WHITBY,
President Elect,
British Medical Association.
Cambridge.

Confidence in the Council

SIR.—I was delighted to read Dr. Alfred Cox's letter (May 15, p. 949). He stressed one point which, I think, cannot be too strongly emphasized. At Headquarters and at H.Q. alone can be found a true estimate of current medical opinion. For this reason it is imperative that we should place complete confidence in the Council.

I know no body of men that is not on occasions liable to attacks of hysteria. Those who have attended Representative Meetings in London will appreciate this as a fact, for, despite our training, we are just as liable to emotional crises as any other branch of the community.

I remember the hysterical outburst before N.H.I. when Dr. (later Sir James) Smith-Whittaker accepted a high executive post on the Commission. I remember it well, for my own outburst of fierce hostility to all in authority in the B.M.A. carried me on a wave of emotion into membership of the State Sick Insurance Committee—the parent of the Insurance Acts Committee. I served for a year and learnt a very great deal.

I don't say that I am happy about the new Health Service—but I do feel strongly that we should be directed by the report of the Council and not try, each and sundry, to force our own point of view on the others. We have a lot of work ahead of us, and this work must be done by an informed

CORRESPONDENCE

MAY 29, 1948

Dr. H. Simpson (p. 950) somewhat impolitely demands reply to question which he more impolitely answers. I beg leave to dissent in his "you know very well that you have achieved little worth in his" and to say you have brought about a state of affairs which "shook myself—and from the figures you have published a good many more—who replied to the first plebiscite that they disapproved of the Act, would not work it, and would abide by the view of the majority, to conclude that they approve of the Act with the promised amendments, will work it, and will not be controlled by a majority in a decision which each doctor has been left by Parliament individually free to make. Obstetric arrangements apart, the only iniquitable thing left I have been able to discover is that, where a doctor after a term of both public and private practice ceases from the former and continues the latter, he is still prohibited from selling the goodwill of the latter. But this is not likely to arise in fact for some years, and by that time amendment of the Act acknowledged by the Minister as likely to be indicated by experience of its working may have in this respect altered Section 35. Those of your correspondents who appear to be seriously of the opinion that retention of goodwill is essential to avoidance of full-time salaried service, and who are not convinced by your demonstration in your leading article that this danger was for the present rid of before the Bill came before Parliament, such as some comfort in the fact that an Act of Parliament, such as that in which Mr. Bevan intends to enshrine his personal guarantee on this point, is the highest safeguard known to our law. There are, of course, safeguards in common and case law; but wherever a liberty is threatened by the executive Parliamentary guarantee is the most anyone can obtain. Although it was wrenched from a medical executive before Parliament were, Magna Carta itself is a freedom of those of us who are coming into the Service. Further, even those of us who do not intend to use the National Health Service, private practice: and if anyone tries to introduce a full-time salaried service we are stronger than we are now or if we stayed outside the man who does not join the Service is; and that, under the Act, means our capital has to be paid to us. It would be a rash Minister of Health who provoked a call on the Treasury for most of the capital sunk in practices when the Chancellor reckons on having to find this in drabbits over the next 40 or 50 years.

Finally, may I advise those who honestly want information to take the Minister at his word and write to the Department? Personal experience since this invitation was offered—and accepted—in January last has provided much concrete information of practical importance, which was of weight in reaching the decision mentioned above and communicated to you in the last plebiscite.—I am, etc..

C. T. NORRIS

The April Plebiscite

Sir.—Will you permit me space in the *Journal* again in order to criticize your leading article of May 15 (p. 936), which indirectly refers in parts to my letter on p. 951 of the same issue? In my opinion this leader is well worthy of the closest consideration by all members of the B.M.A., containing as it does a series of inaccuracies and misstatements. In the light of the most recent developments it is most imperative that we should take a careful survey of all facts. On this account I think, require consideration.

Your paragraph 1.—Although 13,000 G.P.s did not vote against the Service in the last plebiscite a large number did not vote at all, and I maintain that a minority vote of 36% does not by any means justify the Council of the B.M.A. advising 64% to accept the Act against their obvious inclination. Consequently, the Council has no authority to enter into further negotiations with the Minister of Health; the prospect, in any case, of our obtaining anything worth our while, once we have delivered ourselves body and soul into the Health Service, is antastatic. Dr. Alfred Cox (p. 949) may endorse your decision, but the plebiscite of doctors who will have to work in the Service definitely does not. The attitude of the general public, of which only a very small minority (and some of these under compulsion) has taken out registration cards, would suggest to me that wisdom and statesmanship on the part of the B.M.A. Council are rather lost on them. The verdict of the plebiscite is definitely against the Service, and the whole-hearted support of the B.M.A. should be given now, and not after we are at the mercy of the Minister of Health. Dr. Cox states "we have

won a victory—he means we could win a great victory were it not for this craven capitulation to State Capitalism.

Paragraph 2.—I, for one, am taking the *Journal* to task because the sudden and complete change of opinion in its leaders since April 7 requires more elucidation than has been given. I agree that the situation has changed a great deal since December, 1947, but this has been due to the medical profession only—we need give no credit to the Minister of Health for this fact. If we still stood together the situation would change still further to the advantage of doctors and public alike. The right of a doctor to choose his own partner or assistant is no concession—are we to be free men or State servants? As far as I have heard the recommended capitation rate by the Spens Committee was 23s per head per annum, so I fail to see where Mr. Bevan has accepted the findings of the Spens Committee.

The absence of Health Centres (paragraph 3) is due to the fact that the Minister of Health cannot even build the necessary houses for the people. To begin with, the Health Centre was to be the keystone for the whole service, but now there will be no health centres, no new hospitals, and no other buildings for years to come, because they cannot be built—service for health, but good enough as a start to obtain control of an independent profession and the general public all at one time. Negative direction implies that a doctor may practice where he likes in under-doctored areas, otherwise it becomes positive direction—this statement in the B.M.J. contradicts itself. In any case, no doctor would want to go to an over-doctored area.

Paragraph 4 is a confession of failure. The medical profession has not succeeded in the question of right of appeal, it has failed to persuade the Minister to remove negative direction, it has failed to retain the ownership of one's own practice, which is of much importance to general practitioners. Yet these points could be definitely obtained if we stood our ground. The ownership of one's own practice is the only safeguard of our own professional independence and the only barrier against a whole-time salaried service, whether by Regulation or Act of Parliament, and Mr. Bevan knows it and the B.M.A. should know it too and should insist upon it, instead of rejecting over the few paltry concessions which have been made.

Apparently according to the last paragraph the policy of the B.M.A. does not represent the opinions of quite a large number of its members, or is the B.M.A. more concerned with a policy to please the Government than with the opinions of the doctors who pay their annual subscriptions?

If the medical profession reject the compromise it will be representing the great bulk of public opinion as I have found it, and as is shown again by the very small number who have registered. The general public realize this is only another step in a series of controls and regimentation, and in this district the overwhelming majority are bitterly disappointed at the suggestion that the doctors should join the Service. The B.M.A. is either out of touch with public opinion or is ignoring it. The wisdom of the B.M.A. Council may not be as widely acclaimed as the B.M.A. seems to imagine, but will certainly be endorsed whole-heartedly by Mr. Bevan and his satellites in the B.M.A. The Minister of Health will be delighted to have got his own way with so little difficulty. Finally, the suggestion that the B.M.A. will receive enthusiastic support in the moulding of the National Health Service from a profession which is at least 64% against it, and forced into the Service against its will, is so obviously ridiculous that one is surprised that it should appear in the pages of a journal which apparently claims to represent professional strength and wisdom.—I am, etc..

J. MCINTOSH RATTRAY.

Kirkcaldy.

* * We suggest that the elucidation Dr. Rattray seeks is in the first principle enunciated by the Negotiating Committee in 1945: "The medical profession is, in the public interest, opposed to any form of service which leads directly or indirectly to the profession as a whole becoming full-time salaried servants of the State or local authorities." The Government's promised Amending Act is to make it impossible to introduce a whole-time service under the National Health Service Acts of 1946 and 1947.—Ed., B.M.J.

Abject Surrender

SIR,—I feel impelled to write to protest at the abject surrender of the Council of the B.M.A. following the result of the third "panic" plebiscite. I do hope you will publish this letter, as it expresses the feelings of disgust, disillusionment and disappointment of all the doctors of my acquaintance to whom I have spoken, and also the general public. I have had my suspicions of Council ever since they decided to "negotiate" against the expressed will of the profession (first plebiscite). They have consistently underestimated the man with whom they have had to deal. They have insisted on conducting the fight in a "kid-glove" manner.

Largely by the efforts of local B.M.A. Committees, assisted by occasional addresses by members of Council above suspicion, and latterly by the Minister himself as a result of his speech to the Commons shortly before the second plebiscite, the profession attained the surprising and exhilarating 90% unity. The Minister then changes his tune. He requests a meeting with the profession's representatives. He talks nicely and politely to them—in the main. He promises them jam to-morrow, in the form of a few illusory concessions, all after July 5 of course. Even the most naive among school-children would not have been deceived. But the effect on the Council is astounding. A new plebiscite is ordered, results to be back within the week, later extended, but still not enough for mature thought on such a vital and far-reaching decision on our whole future.

Are the Council really surprised at the result? And why should it have taken seven hours to assess the consequences? And did they still retain their kid gloves during the whole seven hours? And why should the S.R.M. have been postponed to such a late date as May 28, a bare five weeks before the appointed day? I and many others think the profession is entitled to an explanation.

The Council appeal for continued unity in the profession, having done their best to destroy that unity. How can unity possibly withstand this base treachery and sabotage? Time is short, but I suggest that at least 26,000 of us are still waiting for a lead, and even now are ready to go on fighting. Are they to be left in the wilderness to fight out their own battle as between conscience and finance? Council should resign immediately. The fighting element in it (which is considerable and the individual members known to the profession) should form a nucleus for a new Council, pledged to carry on the battle until true victory is won. Only by so doing can they possibly redeem themselves and save the profession, which they have so often reminded us constitutes the last line in the battle for freedom.

Finally, public opinion, in so far as they ever did have an opinion, is not against us. They are just frankly disappointed that we have gone, or are going, the way of all flesh when confronted by this Government. Public opinion, Socialist or Opposition, will always applaud a fight for the right.—I am, etc.,

Wolverhampton.

A. E. ROBERTS.

Division in Profession

SIR,—It is refreshing to read words of wisdom from the pen of Dr. Alfred Cox (May 15, p. 949), and as a debtor to him following the first world war I would naturally wish to support his contentions, but the comparisons with the National Health Insurance alluded to in his letter are so wide that one cannot but conscientiously criticize. The National Health Insurance involved only a portion of the people, whereas the new National Health Service is comprehensive and, may possibly leave very few doctors with any alternative to joining the new service. Dr. Cox justly admits a Pyrrhic victory in that attempt to gain the chief security against a whole-time service—namely, the right of private property in the practice goodwill—has been a failure, and still he advises acceptance and pleads for unity in the profession. When there has been such a division in the views of the profession, as evidenced in the last precipitate plebiscite, how is it possible to obtain it, or even expect us to remain united?

The B.M.A. has failed to remain a truly democratic institution. To acquiesce to the minority savours more of the totalitarian State, and to virtually ignore the consultants and advise acceptance by them of unknown terms must surely create a precedent unheard of in the long history of British medicine. The B.M.A. must now face the consequences of its guilt, and a break in the ranks of the Association, although perhaps deplorable, may unfortunately be inevitable.—I am, etc.,

R. BERTRAM BLAIR.

Income in N.H.S.

SIR,—Is it not time for us to learn more about the financial prospects under the Act? One has heard vague statements of a capitation fee of 17s. 6d. to 20s.—deduction from the pool being uncertain. The "ordinary man" may not be very clever but he does know how far his pound note goes nowadays; and the ordinary doctor realizes that Mr. Bevan's assumption that he can deal with 4,000 patients with satisfaction to the patient and himself is quite fallacious. In favourable circumstances an exceptional individual might reach a limit of 2,500.

Under the present conditions there will be no reduction of expenses for the G.P.: he will still have to maintain his house, surgery, car, etc. Must the profession continue to ignore financial facts and pretend income is unimportant?—I am, etc.,

Sevenoaks, Kent.

J. FINLAY ALEXANDER.

Medical Trade Union

SIR,—We have got into a dreadful muddle, and though the nation as a whole is suffering from unsound-mindedness coupled with much "go-getting" by professional politicians we of a people should try not to give way to an excess of emotion in our plight. We were doomed as a profession of free men when the Coalition Government agreed that the whole nation should be insured against accident and illness, and our negotiators presumably agreed to this. The Bill went through both Houses as far as I can recall with practically no opposition inside or outside Parliament. Our representatives and ourselves then suddenly woke up to our plight—too late. Now there is nothing more to be done about State medicine. On July 5 we shall have all State doctors or give up practice, and we who will not do the Act will be paid a salary no matter what we call it.

We face a great deal of negotiation on this salary and on compensation and our terms and conditions of service. For this I hope the personnel of our negotiators will be considerably stiffened. We must realize fully that we have to deal with what can only be called the trade union mentality, and I am not at all sure that we shall be able to do this until the B.M.A. transforms itself into a properly constituted trade union affiliated to the T.U.C. and with all the rights and privileges of a legitimate trade union.

It is my humble opinion that until this is done our terms and conditions of service will be intolerable. It is nothing short of calamity that the medical profession has become involved in politics, but there is the fact, and there is the further fact that trade unionism governs politics and is likely to continue to do so until the full establishment of the Communist State or the extinction of trade unionism, as it exists to-day, through other circumstances.

As a disjointed association of 50,000 men the B.M.A. has no political standing or prestige, while as a profession none has greater. This state of affairs must be altered. Dr. Dain as President of the Medical Professions Union duly affiliated would be quite a different proposition to any Minister of Health—even Mr. Bevan—to Dr. Dain as Chairman of the B.M.A. Council.

May I end by suggesting that £300 p.a. and 15s. capitation fee will be gross underpayment for what we shall be asked to do in the conditions which obtain to-day? As far as I am personally concerned my work will be doubled and my income will remain what it is to-day, and I imagine this will be the case of most G.P.s.—I am, etc.,

St. Osyth, Essex.

R. E. CLARKE

Position of Assistants

SIR,—I was pleased to see the subject of assistants prominent in the *Supplement* to the *B.M.J.* proper. I agree with all that has been said, and I would like to lay down some tentative rules. In the first place, no doctor paid to teach an assistant should be allowed to increase his list. In the second place, any assistant employed for more than one year should be guaranteed a partnership or else freed from his bond not to practise in the district. In the third place, any promise of partnership should be registered with the B.M.A., and a breach of that promise be liable to financial compensation and right to practise in the same district.

MAY 29, 1948

CORRESPONDENCE

On a basis as outlined we would have real professional status
assistants, and the old sweated-labour principle would no
longer obtain. As a profession we might then claim to live up
the principles we allege we believe.—I am, etc.,
DUNCAN BAXTER.

Suspend N.H.S.

Suspend N.H.S.

SIR—This day's issue of the *Journal* contains letters which surely would—must—convince any reader of the support you would have in return for your strongest urging to keep out of the Service. There is still time. Should the profession now agree to serve, it will, as I said at a recent meeting in Chelsea, be guilty of cowardice and of being accessory before the fact of the introduction of an Act which is contrary to the best interests of the people. Now this is what we have been claiming all along. How then can we consent to serve and yet be held guilty of betraying the people?

At the meeting to which I have referred I said that if this Government issued a mandate from the electorate for the prosecution of the criminal code, the Government would be bound to issue a mandate from the villages for the prosecution of the medical profession.

...the interests of the people. Now, I am not a lawyer, but I am a layman. How then can we consent to serve the public without betraying the people? I said that if this Government without a mandate from the electorate for the express purpose suspend the operation of the criminal code against offenders who had been committed to the gallows for a period of five years, our profession ought to advise them to suspend the introduction of the proposed N.H.S. for a similar period or an appropriate time, during which the profession would only too gladly offer to co-operate with Mr. Bevan in devising a service acceptable to all sections of the people. (This suggestion evoked loud applause.) I pray you forgive me for making this last plea, but it is all I can do to save the profession from serfdom of a most degrading quality and the people from being dragged down in their company.—I am, etc.,
A. R. EATES.

A. R. EATES.

Strength of the Profession

Strength of the Profession

SIR.—How refreshing it is to read the letter from Dr. Alfred Cox (May 15, p. 949). The two final paragraphs are particularly on the point. As Dr. Cox says, the time is short. Regulations are in the melting pot: some may be already cooling off and solidifying, and once having taken their new pattern will require much hard labour to reshape to a better design. Constructive suggestions are now urgently required to assist the Negotiating Committee, upon whom rests the responsibility of examining with a critical eye those Regulations now in process of formation and of placing our views thereon before the Ministry.

Committee, upon whom rests the responsibility of looking with a critical eye those Regulations now in force, and of placing our views thereon before the Ministry. Experience of Army staff work leads one to the inevitable conclusion that, in framing an Order or a Regulation, which one hopes to have willingly carried out rather than be used as a basis of discussion only, the people most affected thereby must first be consulted. By this I mean one must get right down to the N.C.O. or private soldier whose co-operation will be required if the Regulation is not to become a farce. This parallel should be closely followed by the "back-room boys" of the Ministry who produce our Regulations. They must be made to realize that you cannot regulate human nature. They must produce something that measures up to the criteria of justice, reason, clarity, and lack of ambiguity either directly or by inference; if this be not so then it were better that it be still-born.

As a case in point I would call the attention of the Negotiating Committee following anomalies. Study the propaganda

NDENCE

pamphlet issued to each of us by Whitehall, dated April, 1948, headed "General Medical Services," under the subheading "Fee Charging." By reasonable inference therefrom a patient who has negligently omitted to secure acceptance as a "risk" by a practitioner until she is actually sick and in need of immediate attention might be treated as a private patient until such time as she has recovered and can then be accepted as a normal risk—a very necessary safeguard for practitioners against dilatoriness on the part of patients. But on reference to Regs. N.H.S., 1948, No. 556, Part IV, para. 13, under subheading "Allocation Scheme" you will find that the Minister coolly suggests to each council that it should take away that implied right and lay upon the practitioner the onus of either accepting the risk free of charge or finding somebody else who will be fool enough to do so.

These Regulations the Minister places the whole onus "at risk" on and after July 5, whether or not the patient has been before that time or indeed before that time to secure to

I submit that by these Regulations the Minister places the population immediately "at risk" on and after July 5, whether or not the individual members thereof have, before that time or indeed within several years thereafter, taken the trouble to secure the payment of their "risk."

But does he offer the practitioners a commensurate premium for their liabilities? A second propaganda pamphlet issued to us all from Whitehall, dated April, 1943, and headed "Remuneration of General Practitioners," supplies the answer in its third paragraph. In effect the Minister appropriates from the taxpayer 18s. per head for 95% of the population and forms a pool. He then proceeds to pull out the plug from the bottom of the pool and invites us to drink from the muddy water left behind. He offers to pay us for the few people who understand the necessity of early acceptance by us and in addition for one-third only of the dilatory ones, for all of whom we have been "at risk" from the commencement of the scheme. We can whistle for the rest.

A recent resolution by Doncaster, forwarded to the Negotiating Committee and the Representative Meeting, is based upon the conservative assumption that at least an equivalent number of the dependants of the present insured population will take full advantage of the benefits offered under the scheme and will sooner or later call upon our services. It requests that the allocation be based at first upon double the numbers of our present panels and be adjusted upwards or downwards at a later date in the light of experience. This resolution seeks only a fair and logical premium for the "risks" forced upon us by the Minister.

Edlington, near Doncaster, York

Remuneration of General Practitioners

Remuneration of General Practitioners

SIR.—In your issue of May 15 in a leading article (p. 936) you state that Mr. Bevan has accepted the Spens Committee's recommendations on remuneration for general practitioners: you do not state that he has implemented them. In a little booklet entitled *The Doctors' Case* it is stated that "the Government has treated the medical profession fairly enough in its arrangements for deciding what doctors should be paid." If you will refer to my letter in the *Lancet* of May 15 (p. 770) you will see how very wide of the truth these remarks are. I should like your readers to realize the true position.—I am, etc.

HAROLD LEESON.

WORTHING, SUSSEX.

A Specialists' Charter

A Specialists' Charter

SIR,—As a gynaecologist my ear is already attuned to the 50 guineas for the 3s. 10d. of the new Health Service. Many of my patients will have in advance prepared to vote into power the Father Xmas of this prospect. And who am I to discourage them when I can also don my shorts and enter into the race for dual honours after a hearty dose of Grimm's—self-synthesized if necessary.

Government is promising complete specialist services. It is quite obvious if the patient is not to be in the future—arising out of the future—

The Government is promising complete specialist services under its new scheme. It is quite obvious if the patient is not paying specific fees to the consultants in the future—arising out of this arrangement—that the Government is aware that its action is definitely spoiling the expectation of earning from specialist practice. Custom has established the specialist's right to this method of earning. Legally if he is dispossessed of this, right he is entitled to damages, unless the alternative arrangement leaves him no worse off financially. There can be no doubt whatever that if the new health scheme succeeds in depriving the specialist of his private practice much financial loss will be suffered by him.

to
his

loss will be sustained by him. The very inelasticity of the envisaged method of payment will alone ensure this.

I would suggest that compensation to the extent of £5,000 for every ten years of specialist service, with a maximum of £10,000, should be the agreed damages for this loss of expectation. Such a course would imply the Government's confidence that its new scheme will save the contributor from paying out fees to specialists, and would underline its honesty.

If a specialist's private practice is largely to be abolished the corollary is that he will have to support himself equally largely out of the salary he is paid for his duties at hospitals to which he is attached. My second suggestion is that £500 per year per appointment is the absolute minimum rate of payment. In addition sessional opportunities for work at a rate of £250 per session should be made available to cope with the pressure of the extra work that in theory should arise, and also to permit the practice-starved specialist to survive without existing on his capital, even if augmented by the aforementioned damages.

Thirdly, I would suggest that the offer of alternative appointment should only be considered if strictly equivalent facilities and opportunities are offered. A take-it-or-leave-it condescension can find no room in the contracts to be signed.

Here I would recommend that a committee of assessors should be appointed. It should be constituted principally of specialists, and if the equivalence of a proposed alternative appointment was in dispute the matter should be submitted to them for adjudication, and their ruling should be binding on both parties of the contract. A similar body should be set up to advise on any differences of opinion between employer and employed. Their services will surely be needed in the future to restrain the commissars on our door-step.

I should like to submit these four points for consideration and incorporation in a specialists' "charter." But above all is there not sufficient time to devise and arrange for signature a mutual form of guarantee among specialists whereby we declare our solidarity in the defence of these principles and our singleness of purpose to explore ways and means to enforce them? We are fortified morally. The change-over means the exchange of freedom for thralldom and the replacement of the principle of reward for striving by the use of the big stick for the lack of effort.

Well turbaned our Minister may traverse our Harley Streets in his quest to exchange his lamp for Aladdin's own. Let the specialists recognize this so that they may live happily ever after.—I am, etc.

J. L. N. W. I.

JOHN SOPHIAN.

Activity of Liver Extracts

SIR: In your issue of April 10 (p. 701) a report is given of a discussion on the megalocytic anaemias at the Royal Society of Medicine on March 23, 1948. I was surprised to read that Dr. J. F. Wilkinson stated that he had never been able to obtain an active liver extract from the liver of fishes after the oil had been removed. I would therefore like to draw attention to the fact that I produced a very potent oral liver extract from fish liver in Aberdeen in 1932, and that a full report of the haematological findings of patients treated with this extract was published in the *British Medical Journal*.¹ Two of the cases were treated with this extract by Dr. Wilkinson himself in Manchester. He reported to me that my extract of fish liver had resulted in the blood count being quadrupled in one case in three weeks and trebled in another case in thirteen days. Acknowledgment was made in this paper to the independent testimony of Dr. J. F. Wilkinson regarding the efficiency of fish-liver extract. It is to be noted that an aqueous extract of fish liver has also been used successfully by Connery² in America. The introduction of parenteral liver therapy shortly after we had successfully produced active oral liver extract from fishes was the reason why this method of production was discontinued, as it is generally agreed by the majority of leading haematologists all over the world that parenteral therapy has considerable advantages over oral therapy with liver or hog's stomach preparations.

Dr. Wilkinson, when discussing megaloblastic anaemias refractory to highly purified liver preparations, stated that it was essential that the individual batch of the liver preparation to be used in the patient was refractory should have been tested for

potency on a classical case of pernicious anaemia. Without such knowledge the refractoriness might be due to an inactive batch of liver extract being used. I would entirely agree with this suggestion. During the 20 years which have elapsed since I first published a report on the testing of liver extract I have tested the activity of a large variety of liver preparations, both commercial and experimental, in many hundreds of cases of pernicious anaemia. I always have at my disposal batches of liver extract of proved potency, which are available for use in cases of megaloblastic anaemia which have failed to respond partially or totally to liver therapy.

Refractoriness to parenteral liver therapy occurs most frequently in nutritional megaloblastic anaemia, in megaloblastic anaemia associated with the sprue syndrome and pregnancy, and in a small number of cases of megaloblastic anaemia in which no cause for the refractoriness to parenteral liver therapy can be discovered. In all these groups free hydrochloric acid may or may not be present in the gastric juice. The degree of refractoriness depends partly on the type and potency of the liver preparation given and its route of administration, and partly on personal factors in the patient, some of which are known and others of which are unknown. It is therefore essential when defining refractoriness to liver therapy to state clearly the criteria used.

In a paper entitled "Refractory Megaloblastic Anaemia," which appeared recently in *Blood*,³ I have defined the term "refractory megaloblastic anaemia" as used by myself, and submitted records of a variety of cases of megaloblastic anaemia which failed to respond to potent preparations of purified liver extract and thereafter responded to folic acid or protected liver. Anyone interested in refractory megaloblastic anaemia can consult this paper for further details.—I am, etc.,

Edinburgh,

L. S. P. DAVIDSON

* Dr. J. F. Wilkinson's paper, to which Prof. Davidson refers, was read at a meeting of the Royal Society of Medicine and only a shortened version was published in the *Journal*. To avoid misunderstanding we showed Prof. Davidson's letter to Dr. Wilkinson, who tells us that what he in fact said at the meeting was, "Extracts of fish livers (cod, halibut, salmon, etc.), and also whale liver, when prepared from fresh livers, are haemopoietically very active, both orally and parenterally, but commercial fish and whale liver discards (residues) after the extraction of their respective oils by superheated or live steam do not furnish active preparations at all . . . and I have yet to obtain an active liver extract from reptilian and amphibian livers."—Ed., *B.M.J.*

"Alkalosis" and the Effects of Alcohol

SIR,—I was interested to read the medico-legal case concerning alkalosis and the effects of alcohol (May 1, p. 861). It immediately called to mind a case under my care in 1936 when I was a house physician.

My patient, aged somewhere in the late forties, had a radiologically proven active duodenal ulcer. My Chief ordered his routine treatment at that time, which included 1-2 hourly feeds, with alkali 2-hourly, but not belladonna or atropine. Within a day or so of the onset of this treatment the experienced sister-in-charge said to me that the behaviour of this patient was a bit odd at times. The following morning the night report showed that the patient was getting out of bed and had threatened to commit suicide. In the morning when I spoke to him he was most confused; his concentration was very poor, as was his memory, and it was not possible to hold his attention for any length of time. He would keep looking all around him, was restless and fidgety. Of course delirium tremens leapt to mind. However, the mental confusion and the furred and dry tongue reminded me of a case of uraemia that I had seen, and a blood urea estimation was made. This showed a blood urea of 144 mg. %.

A tentative diagnosis of alkalosis was made. Alkali administration was stopped at once and the patient given frequent meals of well cooked, easily digestible, and palatable food. By the next day I was much better. Blood urea estimations were carried out every 3 or 4 days; they eventually dropped to within normal limits. There was no other cause for the uraemia it was now presumed was the cause of this as well as the patient's abnormal conduct with alkalosis. I must add that there never was hypertension, nor any abnormal findings on ophthalmoscopy, and that the urine never showed any albumin, red cells, or casts. At no time had the

CORRESPONDENCE

MAY 29, 1948

an oedema, diarrhoea, or vomiting. No other drugs had been given and the patient's conduct prior to the commencement of treatment in hospital had been normal. The patient was now a pleasant and co-operative individual who was rather vague about what had been happening to him during the days when his behaviour was abnormal. He scarcely ever touched alcohol because of his disability and had no previous history of mental aberration.

It is not too difficult to imagine what might have happened to this patient over-indulged in alkalis as an out-patient and had one whisky in milk, as some individuals I know are apt to do, followed by a car accident. The examining doctor would have observed a smell of alcohol and abnormal conduct, especially with the excitement of a car accident and a medical examination in such circumstances. Might not a doctor be excused for insisting on a diagnosis of alcoholism when the abnormal mental conduct would be predominantly the result of alkalosis?

A colleague of mine informs me of a case of urinary infection who died from alkalosis in the pre-sulphonamide days, when massive alkaline therapy was the order of the day. A blood urea estimation was suggested by an astute and enthusiastic nurse who had been sweating Price. It would appear to me that alkalosis should be kept in mind in all cases where alkalis are administered, especially when massive alkaline therapy is adopted. I have never forgotten the case that I have just described, and it has served me well.—I am, etc.,
JOHN MACLEAN-DICK,
Lt-Col R.A.M.C.

B.A.I.R.

The Mystery of the Eosinophil

SIR—Some years ago I took considerable interest in the eosinophil, and it left me with the impression that it is part of a defence mechanism, and that the occurrence of eosinophilia is not otherwise explicable suggests the presence of a known, unknown, or facultative allergen. Morphologically, the polynuclear leucocyte and the eosinophil are practically identical. They differ only in their staining reaction and granularity. The production of eosinophilia is provoked experimentally by infestation with intestinal blood helminths, and it appears that the resulting eosinophilia is a response to a specific stimulus, in effect a foreign protein, a modified polymorph, in fact. In true allergic bronchospasm the exudate from the upper air passages is crowded with eosinophils, and in sensitive persons the spasm may be induced by various air-borne allergens—which appears to be not without significance.

There is not space in a brief letter such as the present to discuss all the conditions in which eosinophilia is a marked feature, but a line worth following is based on the theory that the granules in eosinophils are possible precursors of lysins the object of which is to effect lysis of a result; and not a cause, and when it is present the cause has still to be sought. My work convinced me that eosinophilia is a result; and not a cause, and when it is present the cause has still to be sought. I certainly cannot agree with the "overflow" theory of eosinophilia in lymphadenoma, the cause of which is still unknown. In "eosinophilic granuloma" of skin the name suggests that eosinophilia is the cause of the granuloma rather than the result. It is also in "tropical eosinophilia" and eosinophilic disease of the lungs. I have seen individuals who give an abnormal eosinophilic response to trivial or comparatively trivial causes, for example, a 60% count in a case of sunburn with a so-called "herpetiform" eruption of the lip and cheek. I am certain that further work on the subject is long overdue and would be amply repaid, just as I am convinced that eosinophilia is protective in intention and never causative, however high the count.—I am, etc.,
H. M. STANLEY TURNER.

Brookwood, Surrey.

Treatment of Phlebothrombosis

SIR—Mr. Hamilton Bailey's article (March 27, p. 594) emphasizes the need of active treatment for patients with post-operative thrombosis and pulmonary embolism. There is certainly great need for this emphasis, since complete immobilization of the leg for several weeks is still a common practice. Nor is this surprising, since the majority of textbooks published during the last two years still advise this conservative treatment

for femoral thrombosis. The diagnosis of incipient deep vein thrombosis is rarely even mentioned.

Nevertheless I do not believe that figure of the femoral vein is the solution to the problem for the following reasons. First, in certain cases of pulmonary embolism, especially following gynaecological operations, the site of origin of the embolus cannot be detected in spite of careful examination of the legs. Would Mr. Bailey here advocate the ligation of the inferior vena cava, a serious operation in an ill patient, however expertly it may be performed? In the second place, the end-results of thrombosis of the deep leg veins must be considered. Bauer has shown that nearly four out of five of such patients eventually develop a leg ulcer. It is difficult to believe that the ligation of the saphenous and common femoral veins in a patient who already has obstruction of the deep venous channels will not increase venous stagnation and consequently the risk of developing an ulcer. As the regulation of chronic venous stagnation may take ten years to develop, the end-results of venous interruption may be more severe than is supposed.

On the other hand the anticoagulant drugs have been shown to be at least as effective as femoral ligation in the treatment of venous thrombosis and pulmonary embolism, as was demonstrated by Mr. Gavin J. Cleland (April 17, p. 55). They have the added advantages of controlling the spread of thrombosis to the opposite leg, which occurs in 30% of cases treated conservatively. Moreover, as Zilliacus has shown, anticoagulation treatment prevents the chronic swelling and ulceration which otherwise frequently occurs. From the practical standpoint heparin is usually not difficult to administer. I have found that patients prefer a continuous drip transfusion to intermittent injections, provided the needle is inserted at the wrist and not at the elbow. The production of a suitable delayed-acting heparin, such as heparin which is now being used in the United States, would make heparin treatment much easier still. The cost of treating a patient with heparin is often no more than that of keeping him for one week in hospital. As the use of anticoagulants reduces the stay of the patient in hospital by four to six weeks it is indeed economical.

Where facilities for the estimation of the prothrombin concentration of the plasma are available, a combination of heparin and dicoumarol is probably the best treatment available. I agree with Mr. W. M. Capper (April 24, p. 897) that vein interruption may be necessary for cases in which anticoagulants are contraindicated, but I believe they form only a small minority. For most cases the anticoagulants are completely effective and should, in my opinion, be considered as essential to the treatment of venous thrombosis as insulin is to that of diabetes.—I am, etc.,
London N.W.

KENTH BULL.

Origin of Depression

SIR—The publication of Dr. W. Clifford M. Scott's paper on "A Psycho-analytic Concept of the Origin of Depression" (March 20, p. 538), which he delivered to the Section of Psychiatry at the International Congress of Physicians last September, has provided an opportunity for more careful consideration of his views. In opening the discussion at the meeting I felt bound, though with some diffidence as laying no claim to be abreast of recent developments in psycho-analytic theory, to raise anew that often repeated doubt about the reliability of "memories" referred back to infancy, to which Dr. Scott and others of the Freudian persuasion attach a fundamental importance. Especially in such emotional states as depressions which are profound enough to call for intensive treatment, how can we ever really recall what went on in our minds at the tender and largely unmyelinated age of 2 or 3, unless indeed, as must often happen, we have been told by our parents at some later date what happened to us then and how we reacted?

Even when true memories are recalled under psychological investigation, the mood of what is recalled from the past and the influence attached to past experiences. Are we to assume that all depressions are determined by past experiences, rather than they determine what is recalled about the past? As a report of the discussion which followed Dr. Scott's paper is being published, I take leave, Sir, to make these observations.—I am, etc.,
W. S. DAWSON, to,
Sydney.

Histamine and Heat Stroke

SIR.—In the annotation (May 8, p. 887) and in Prof. J. H. Gaddum's paper (p. 867) reference is made to the work of J. Dekanski on the increase of histamine in the whole mouse after hyperthermia.

Histamine shock is very like the condition found in experimental animals (*British Encyclopaedia of Medical Practice*, Cum. Suppl., 1948, p. 172) and the definition of shock given by Moon, "Shock is a circulatory deficiency neither cardiac nor vasomotor in origin, characterized by decreased blood volume, decreased cardiac output (reduced volume flow) and by increased concentration of the blood." The deciding factor in this type of shock—and in histamine shock—appears to be uncontrollable dilatation of the intramural pores of the capillaries. Much clear fluid may be found in the abdominal, pleural, and pericardial cavities. Shock of this type was also visualized by Dale and Richards, to whose work reference is made in Prof. Gaddum's paper. In his words, "There are many kinds of shock," but the shock that is such an obstinate complication of heat stroke or hyperthermia in man presents many of the features of—and may well be—this histamine shock.

If it indeed proves to be the case that heat-stroke shock and histamine shock are the same, a really potent antihistamine drug may find a valued place in the immediate treatment of this medical emergency which, under modern conditions, ends only too often in disaster.—I am, etc.,

Epping, Essex.

FRANK MARSH.

Transfusion Reactions

SIR.—I have read with great interest the article by Dr. John Wallace and Mr. R. D. Richards (April 3, p. 640). I am having printed a statistic about the courses of 795 transfusions made in the hospitals of Milan, which show in the 25.4% of cases reactions of various nature and seriousness that can be classified as follows:

Nature of Reaction	No. of Cases Observed	Percentage
Fever	111	13.9
Shivering without fever	40	5.2
Headache	9	1.1
Vomiting	7	0.9
Shock	7	0.9
Nettle rash	7	0.9
Cramps and convulsions	5	0.7
Feeling cold and tinglings	5	0.6
Retrosternal pains	4	0.5
Deaths	3	0.3
Articulation pains	3	0.3
Dyspnoea	2	0.2
Petechiae	2	0.2
Venous spasm	1	0.1
	1	1.1

I perfectly agree with the authors of the work above mentioned about the pathogenesis of these reactions, and from my point of view I insist upon the educational control of those who carry out the transfusions in order to avoid anaphylactic transfusional reactions, and chiefly upon the most careful cleanness and sterilization of the technical apparatus.—I am, etc.,

The University, Milan.

RINALDO BEVACQUA.

Pain in Phantom Limbs

SIR.—A large number of doctors realize that pain in phantom limbs is of central origin, due to faulty registration of afferent impulses. Heroic surgical procedures—I will not recount them—invariably fail. They betoken complete lack of insight into aetiology on the part of the surgeon.

Dr. J. Donaldson Craig finishes his letter (May 8, p. 904) with the words, "Simple methods of proven efficacy are available." May I draw attention to a simple method of proven efficacy, and one which is, I think, based on a proper conception of the distressing condition?

My experience of treatment goes back to the aftermath of the First World War. There was no lack of amputation stumps on which to put the method into practice. During the 25 years which have elapsed, however, the method has been used mostly by the groups of industrial accidents. The underlying conception of the condition is that in amputations there is a frequent tendency for the

sufferer to block afferent impulses at the level of the thalamus—thalamus being the central relay station for pain. If this block can be overcome, the peculiarly distressing thalamic over-reaction replaced by normal discriminative cortical sensation. The patient once becomes comfortable.

Now as to procedure—the important thing is to persuade patient to put up with a brief period of over-stimulation. Explain things first, then start manipulation of the painful stump. This manipulation should be firm from the start and should become increasingly heavier and heavier. After the first few minutes patient ceases to flinch. Normally within, say, twenty minutes will put up with the heaviest manipulation, squeezing, hitting, banging. In half an hour the thalamic over-reaction, with all its affective qualities, has ceased to operate.

The patient should then be able to bear all normal pressure contacts—e.g., the wearing of an artificial limb. One point is of real importance—from the time of treatment the patient must be nursed to nurse the offending stump. The same principles apply to pain abdominal scars. Do not nurse and protect them, hit them!

I have little belief in neuromata as the cause of distressing pain with the marked affective reaction seen in these cases. When any nerve is cut a neuroma forms, but to attribute pain of phantom limbs to this condition is wrong. The error would be of less importance if it did not lead sometimes to atrocious treatment.—I am, etc.,

Bristol.

HUGH H. CARLETON

POINTS FROM LETTERS

Neurosis and Religious Denomination

Dr. J. COWEN (Radcliffe-on-Trent, Notts) writes: Dr. Slater's article on "Neurosis and Religious Denomination" (*J. ment. Sci.* 1947, 93, 392), and your annotation (May 8, p. 889) upon it, remind me of a remark attributed (I think) to Ferenczi, to the effect that religion is a public psychoneurosis; a psychoneurosis is a private religion. I heard this late in 1942, when I was a trainee psychiatrist at a military psychiatric hospital, and it occurred to me then that there might be an inverse relationship between incidence of neurosis and orthodoxy in religious adherence. . . . Dr. Slater suggests that the progressive rise in incidence of neurosis among Jews during the course of the war may have been due to their greater susceptibility to home-separation anxiety. I would add to this other possibilities. Thus, the demands of Service life enforced a departure from the orthodox ritual practices of the Jewish home—the resulting weakening in religious faith may have increased a predisposition to neurosis. Also, at the beginning of the war, the morale of Jewish Servicemen was high, because they believed that the defeat of Nazism would mean the end of anti-semitism; whereas it became apparent that anti-semitic feeling was not vanishing automatically with the disappearance of the Hitler régime. The consequent drop in morale, and the resurgence of feelings of insecurity *vis-à-vis* this new world they were helping to fight for, took heart out of their effort, and an escape into psychopathy was almost inevitable.

Advantages of Service

Dr. H. S. GRIFFITH (Wolverhampton) writes: . . . If we have a service why not concentrate on obtaining the advantages of one, for advantages there undoubtedly can be, not so much perhaps for the big business men of the profession but certainly for single-handed ones—and their wives.

Credé's Method

Dr. J. F. DEVLIN (Leeds) writes: I was rather interested in discussion on Credé's method reported in the *Journal of April* (p. 748). Credé's method, or better known to me as the Dub method of expression of the placenta, as taught in the Dublin School was the expression of the placenta after it had separated from uterus and had descended into the vagina; as a method to try induce separation of the placenta it was liable to produce either adherent placenta or post-partum haemorrhage. . . .

Hyperidrosis

Dr. EVA MCCALL (Sunninghill, Berks) writes: As Mr. H. Haxton (April 3, p. 636) states that the aetiology of hyperidrosis is often obscure, it may be worth while recalling that this condition was a marked feature among the victims of the serious epidemic arsenical poisoning in beer drinkers which occurred in the Manchester district in 1901. Many of the cases came under my care in Salford Union Infirmary, and in fact supplied me with material for my M.D. thesis, and I even now recall that hyperidrosis especially of the palms and soles, was often present.

Obituary

IR GEORGE BLACKER, C.B.E., M.D., F.R.C.P., F.R.C.S.

Consulting Obstetric Physician, University College Hospital

Mr George Blacker, who died on May 21 at Frensham, Surrey, where he had been living in retirement for some years, was a leading figure in obstetrics in London for three decades. His work at University College Hospital Medical School and as an examiner helped to raise the level of teaching in midwifery thirty years ago. He took an active part in the discussions on his subject which were started by the Section of Obstetrics and Gynaecology of the Royal Society of Medicine, and continued in the medical press, immediately after the first world war. Blacker urged the provision in different parts of London of four or more large lying-in institutions where the student could receive his practical teaching in midwifery, gynaecology, and maternity and child welfare all under the one roof. The institutions which he proposed were to be large enough to provide for all medical students in London and to be officered by whole-time properly paid senior teachers. In some respects he was in advance of his time on educational as well as on other problems.

George Francis Blacker was born in Dublin in 1865, the husband of Miss Latham Blacker, member of a well-known military family in County Tyrone. He received his education in England, at Cheltenham College, a school for which he always retained affection. Forty years after leaving it he became president of the Old Cheltonian Society. From here he passed to University College, London, and thus began a connexion with the Gower Street hospital which lasted for the rest of his life. Blacker's career as a student was brilliant. In 1888 he was exhibitor and gold medallist in anatomy and materia medica and pharmaceutical chemistry in the University of London; in 1891 Atkinson-Morley surgical scholar, and in the same year he took the M.B., B.S. London with the gold medal in surgery and obstetric medicine, and became a Fellow of the Royal College of Surgeons of England. Two years later he took his London M.D., qualifying for the gold medal. In 1902 he was elected a Fellow of the Royal College of Physicians.

University College Hospital Medical School has had many able teachers in obstetrics, and Blacker's name stands high amongst them, alike for the soundness of his teaching and the strength of his personality. For many years he was lecturer in midwifery in the School, and for a long period he was dean. During his deanship the Rockefeller gifts were made to the college and the medical school—namely, the income from the sum of nearly half a million pounds to be used in the furtherance of medical education and research, and a further annual sum for the upkeep of 120 beds in the medical and surgical units. On his retirement in the early 'thirties he was made consulting obstetric physician to the hospital; he held a similar position at the Royal Northern Hospital. He was also a Fellow of University College. At various times Blacker had acted as examiner in midwifery to the Conjoint Board and to the Universities of London, Liverpool, and New Zealand. His busy practice and teaching duties left him little time for writing, but he was an occasional contributor to the medical journals, and he edited the seventh edition of Galabin's well-known *Practice of Midwifery*. He was interested in the application of radium in medicine, and in 1929 became president of the Radium Institute in succession to Sir Anthony Bowlby: he was, too, vice-president of Mount Vernon Hospital. He was also at one time president of the Section of Obstetrics and Gynaecology of the Royal Society of Medicine. Another of his interests was the Red Cross movement, and he was honorary life member and for a time chairman of the Farnham Branch of the Red Cross. Blacker served in the 1914-18 war with the rank of captain, R.A.M.C., and was twice mentioned in dispatches.

In 1920 he was appointed Commander of the Order of the British Empire and received his knighthood three years later. He married in 1904 Miss Shirley Bowen, daughter of Canon T. J. Bowen, of Bristol, and had one son. On his retirement he sought a quiet retreat in Hampshire and later in Surrey. He was a man

without ostentation, of simple tastes and quiet mind, and it was in keeping with the spirit of his life that he should have desired at his death no mourning and no memorial service.

ROBERT OLLERENSHAW, M.D., F.R.C.S.

The sudden death of Mr. Robert Ollerenshaw, although not unexpected even by himself, came as a great shock to his many friends, acquaintances, and colleagues, for he seemed to be in comparatively good health. He had been forced to restrict his activities following a severe attack of angina in December, 1946, yet despite not infrequent attacks of pain he remained his usual cheerful and genial self in the intervening period. In the morning of May 19 he performed an operation and then had lunch with the director of the Hallé Orchestra, discussing plans for the forthcoming trip to Austria, on which he intended to accompany the Orchestra in his capacity as a member of the committee of many years' standing and as the honorary medical officer. After lunch at the Clarendon Club he was indulging in his usual cup of coffee when he collapsed and died.

Robert Ollerenshaw, the son of George Ollerenshaw, J.P., of Glossop, was born at Blackburn in 1882. He was educated at Manchester Grammar School and at Owens College. He graduated M.B., Ch.B. in 1905 and proceeded M.D. three years later. He took the F.R.C.S. in 1909. As a student, Ollerenshaw was outstanding at soccer and an excellent tennis player. His postgraduate training continued at London and Berlin and he held resident posts at the Manchester Royal Infirmary and the Liverpool Children's Hospital. His early surgical career was that of a general surgeon, and in the 1914-18 war he acted as a surgical specialist with the rank of major in the R.A.M.C. He served with the Second Western General Hospital, as did the late Prof. A. H. Burgess and so many other Manchester surgeons, and subsequently with the 57th General Hospital in France.

Soon after his return Ollerenshaw restricted his interests to orthopaedic surgery and was appointed honorary orthopaedic surgeon to the Royal Manchester Children's Hospital and to Salford Royal Hospital, and visiting consultant orthopaedic surgeon to Booth Hall Hospital. He relinquished the latter appointment in 1940 and retired from the active honorary staff at Salford Royal Hospital on reaching the age of 65 in 1947. His services to this hospital were recognized, to his delight, by his appointment to the board of management. The Orthopaedic Department which Ollerenshaw established at Salford Royal Hospital was one of the first in the country; and those of us who worked with him found him a genial tyrant who could not devote too much attention to details. His professed motto was "Nothing but the best," and he had a tremendous capacity for inspiring all those who were associated with him. He could be as sympathetic and tender as a mother in dealing with his small patients and those who were ill, but he had no use for those whose complaints were imaginary.

Robert Ollerenshaw was a member of many professional societies and had been president of the Manchester Surgical Society and of the Orthopaedic Section of the Royal Society of Medicine. He was a vice-president of the British Orthopaedic Association and of the Section of Orthopaedics at the 1929 annual meeting of the British Medical Association. He was a Fellow of the International Society of Orthopaedic Surgery and an honorary Fellow of the French Orthopaedic Association. His publications covered many subjects; that on the development of cysts of the semi-lunar cartilage is probably the best known. He was also responsible for sections of several textbooks and for a number of papers on orthopaedic problems.

As a teacher he was superb, and at least two decades of students have benefited from his lectures and demonstrations as clinical lecturer in orthopaedic surgery at the University of Manchester. He was appointed lecturer in 1926 and was one of the pioneers in the use of films for recording and teaching. With the assistance of his sons he made the first coloured cine film of an operation—his treatment of pes cavus.

To omit mention of his non-professional life would present a very one-sided picture of "Bob"—as he was to his friends. He was a *bon viveur* and he delighted in the company of his fellows, particularly if musically inclined. He belonged to clubs and societies, but was happiest when entertaining in his

home at Didsbury, where for many years until her tragic death in 1933 his wife, Florence, daughter of Senator Robert Watson of Portage-la-Prarie, Manitoba, was a charming hostess. Not only were friends, colleagues, and house-surgeons welcome guests, but many famous personalities of the theatrical and musical world, notably Sir Henry Lytton and Nicoli Malko, often stayed there. His abiding interest and passion was the Hallé Orchestra, and he rarely missed a concert. He was not content only to listen but gathered around him a small group of friends and relatives and delighted to take part in small orchestral concerts in his own home. His two sons, both of them members of the medical profession, joined their father in this relaxation.—W. S. C.

PROF. A. H. BURGESS, M.Sc., F.R.C.S., LL.D.

Prof. Geoffrey Jefferson writes: An old house-surgeon of the late Arthur Burgess must pay his tribute to his old master. It was apparent to one like myself who worked for a senior (G. A. Wright) as well as for an assistant surgeon (as Arthur Burgess then was) that the latter represented the change from the old to the new in surgery. Wright was the perfect example of the traditional British school with Sir James Paget and Lord Lister as models—men of great character, great probity, great intelligence, and with all that a certain air of aristocracy and wide cultural background. There was an air of scholarship about their work which seems somewhat unnecessarily to have been lost. Burgess brought a more clearly defined air of professional precision into surgery. There was to be a new care now about technical detail, a new insistence on asepsis, on preparation, on instrumentation, on tactics rather than strategy. It was by Burgess as much as anybody else that the safety and ease of all kinds of abdominal operations were brought to so high a pitch, certainly one greatly superior to, and more successful and more adventurous than, anything that his seniors had achieved. When anyone writes, thinks, or speaks on such matters the names of Mayo Robson and Moynihan must perforce come up, protestingly perhaps against the claims of others. It was valuable historically that Burgess was younger, for it made it possible for him to support at the time and later to continue the work so well begun. Moreover (a favourite word of Burgess's), abdominal surgery was brought to its high summer not by Moynihan alone but by a group, each of whom added something personal. Burgess's work was completely sincere, there never was a less evasive man in his work or anything else. Industry, sobriety, thoroughness, honesty, are the words that best express him—indeed he could not always restrain his irritation over the claims made by those whose sense of artistry caused them to advance statements that were more "required" than exact, who indulged thus in scientific romanticism. Burgess had no sympathy for impressionism in surgery. Burgess was a true technical artist himself, but that everybody knows or, alas, knew. Burgess excelled in another important way—namely, his encouragement of the younger surgeons, not of one pupil alone but of several. Considering what a busy man he was, what a hurry the tall figure was always in, walking with brisk steps and straight back, one asks how he could have had time for anyone. Perhaps he hadn't much, for no one has in his busiest and most creative years, but one could rely on a smile, a pat on the back, and a word of encouragement. Certainly "young Jefferson," as Arthur Burgess always called the writer, will ever be grateful to that upright gentleman and great surgeon, pioneer and perfecter in the surgery of the abdominal organs.

PROF. JOSEPH SEBRECHTS

Surgeons in this country will learn with great regret of the death of Prof. Joseph Sebrechts at the comparatively early age of 63. The funeral took place on April 2 and a service was held at the St. Sauveur Cathedral.

Mr. H. W. S. Wright writes: A visit to Bruges is always long to be remembered, and most of us at some time or other have visited his clinic. When one thinks of Joseph Sebrechts, recollection of the mass of clinical material at his disposal, his diagnostic skill, his pioneer work on spinal anaesthesia, and his personality, crowded into one's mind and are inseparable from the thought of the beautiful town in which he worked and lived. It was a privilege to see the Memlings is still a

fresh and unforgettable experience. When Prof. Sebrechts went to Bruges in 1910 it was an unimportant provincial hospital; when he died at the end of March this year he had built it up into the most important centre of postgraduate teaching in that part of Belgium. Bruges is not a university town, but Sebrechts was an honorary professor of the University of Louvain.

A general surgeon in the widest sense, he was best known in this country for his abdominal surgery and his work on spinal anaesthesia. His views on the fractional dosage of hypobaric solutions were developed as the result of 25,000 cases, and were embodied in several papers published in this country. Altogether he had operated on more than 100,000 cases under anaesthesia produced in this way. In the long run he will be best remembered neither for his skill nor for his experience but for his humour, his friendliness, and his hospitality. In his own part of Belgium he was beloved by rich and poor, by doctors and assistants, for the way his time and energy were at the disposal of anyone who needed his help, his advice, or his skill. He thought little of the honours he obtained. He wanted most to be a good doctor and a good citizen. Those who lived alongside him will agree that he succeeded in both these objects.

He was an honorary Fellow of the Association of Surgeons of Great Britain and Ireland, and a Fellow of the Royal Society of Medicine and of a great many Continental and Belgian professional societies. His wife and family are assured of the deep sympathy of his British colleagues.

CAPTAIN E. C. WATSON, D.S.O., R.N.

The late Captain E. C. Watson, who died in August last, was a distinguished naval officer before he took up medicine. Edward Clifford Watson became a medical student after twenty years' service in the Royal Navy, retiring with the rank of commander. He qualified in 1930 as a student of St. Mary's Hospital and was resident obstetrical officer there. He was promoted captain on the retired list in 1932, by which time he was in active practice with a partner in Twickenham.

Dr. J. B. Gurney Smith writes: May I be allowed to pay my tribute to a very versatile member of our profession. Captain Watson resumed his naval career in 1939. He served continuously afloat throughout the war, mostly in command of H.M. minelayers. He commanded H.M.S. *Port Quebec* and H.M.S. *Teviotbank*, in which latter ship I served under him as his medical officer for close on two years. He had a deep love for the sea and was an accomplished sailorman. During his command of the *Teviotbank* he was awarded the D.S.O. for his services in minelaying operations, a decoration which gave his officers considerable pleasure.

He had a profound knowledge of electrical engineering, having taken the M.I.E.E. before he entered the medical profession. He was an Admiralty consultant on radio problems during the first world war.

Captain Watson was a man of considerable charm and had a powerful personality. He was always most helpful to me at his medical officer, and I had the utmost confidence in his judgment on matters of importance. He had a wide knowledge of general affairs and read deeply. He taught himself foreign languages when we were in harbour. Although he had been out of touch with naval affairs for the period between the wars, yet he remembered all his seamanship and navigation. At the close of the war he would often invite me into his cabin to discuss medical matters. He was a most avid reader of the *B.M.J.*, which he received regularly at sea.

Our profession has lost a remarkable character and I feel sure that a host of one-time naval and medical colleagues will be the poorer for his passing. He spent his last days as health adviser to the Government of Trinidad, where he succumbed to a coronary thrombosis. A fine sailor and a very successful doctor has gone to his reward.

Dr. ERNEST GRAHAM YOUNG THOM died at his home in Lanark, on May 8, after a short illness. Graduating M.A. in Glasgow University in 1907, Dr. Thom took his M.B., Ch.B. in 1913 and, following the first world war, began practice in Lanark. He retired in 1937, and in the same year was elected to the Lanark Town Council, becoming a baillie in 1946. He was secretary of the Lanarkshire Division of the British Medical Association from September, 1939, until May, 1947.

MEDICO-LEGAL

Medico-Legal

STILBOESTROL AS A CAUSE OF CANCER
[FROM OUR MEDICO-LEGAL CORRESPONDENT]

A new form of medical malpractice is alleged in a report from California of a suit brought by an ex-patient. The doctor pleaded that the action was barred by lapse of time. The trial court dismissed the complaint, but the district court of appeal held that the State's statute of limitations does not begin to run until the patient knows, or with ordinary care should know, the cause of his injury, and therefore allowed the action to proceed. This is as far as the report goes, but the allegations are interesting.

The patient says that from January, 1942, until June, 1943, the physician prescribed a substantial quantity of medicine containing stilboestrol in tablet form, and on June 1 ordered a hundred more tablets to be taken at the rate of one a day. She had taken these tablets she took twenty-six more. The advice of another physician, whom she is also suing, is further alleged that stilboestrol is a synthetic oestrogen containing cancerous properties which may produce or cause cancer of the breast, especially in a woman with a family history of cancer of the breast, and that it should not be administered for prolonged periods, and only after a physical examination. She says that the physician knew that she had such a family history, for her mother had died from cancer of the breast. About Jan. 15, 1945 she says, while she was under the care and treatment of this physician and another, a lump developed in her right breast which laboratory tests disclosed to be cancer. On Feb. 10, 1945, she had an operation for removal of the breast.

The result of the action will be awaited with interest. The patient's obvious difficulty is to establish, in the present state of knowledge of the carcinogenic properties of oestrogen (if any), the required link of causation between the substance and the disease, and also that the treatment prescribed showed want of due skill and care.

J. Amer. med. Ass., 1948, 133, 712.

Medical Notes in Parliament

Biopsy on Mutton

During Captain CROWDER on May 12, Dr. SUMMERSKILL the Regulation in Statutory Instrument No. 886 of 1948 made to permit the importation of carcasses of mutton from which a lymphatic gland had been removed. The Regulations were now in line with those of the Southern Union, where such meat was ordinarily used for human consumption. A very careful examination was made. The lymphatic glands were all removed. If a state of emaciation was ascertained, superficial-inguinal, supra-mammary, and precarinal glands were removed. The carcass was destroyed. The glands and the glands were affected, as happened much more often with mutton than with beef, the carcass was destroyed. The Ministry wished to make quite sure that the complaint was not communicable to human beings. For that reason the amended Regulation had been delayed. The meat used would be the same as any other meat which had not had the lymphatic glands removed from it.

Paying Patients

Mr. MITCHISON on May 14 asked whether anyone who was the paying patient of a general practitioner not undertaking to provide medical services under the National Health Service Act would be entitled to use the hospital and specialist services available under Part II of the Act; what steps should be taken by or on behalf of such a patient if it was found that he required those services; and in what respect his use of them would differ from their use by a patient who had been accepted by a doctor for general medical services under the Act.

Mr. BEVAN's answer was that the same hospital and specialist medical services under Part IV of the Act or not. Normally he would be referred to these services by his doctor, but he was not barred from getting them otherwise.

The Services

Air Vice-Marshal P. C. Livingston, C.B., C.B.E., A.F.C., has been appointed Honorary Surgeon to the King in succession to Air Marshal Sir Andrew Grant, K.B.E., C.B., K.H.S., who has relinquished the appointment on retirement.

Surgeon Lieutenant-Commander J. L. Holgate, R.N.V.R., has been awarded the R.N.V.R. Decoration.

Colonel C. H. Budd, M.C., T.D., D.L., has been appointed Honorary Colonel, No. 6 (E) General Hospital.

Colonel A. H. Whyte, D.S.O., T.D., has been appointed Honorary Colonel, 50th (N) Infantry Division, R.A.M.C., in succession to Colonel W. E. Hume, C.M.G.

The following decorations have been conferred by the President of the U.S.A. in recognition of distinguished services in the cause of the Allies:

Legion of Merit, Degree of Officer.—Brigadiers (Temporary) H. L. Garson, O.B.E., M.C., T.D., and Sir Lionel E. H. Whitty, K.C.V.O., M.C., R.A.M.C.

Bronze Star.—Major R. Pollock and Major (Temporary) W. R. Henderson, O.B.E., R.A.M.C.

The following decorations have been conferred by the Prince Regent of Belgium in recognition of distinguished services in the cause of the Allies:

Officer of the Order of the Crown.—Lieutenant-Colonel A. Harrison-Hall and Lieutenant-Colonel (acting) H. V. B. B. O.B.E., R.A.M.C.

Officer of the Order of Leopold II.—Major (Temporary) C. L. M.C., late R.A.M.C.

Officer of the Order of Leopold II.—Major (Temporary) E. A. Harris, Gallagher, O.B.E., R.A.M.C.

Croix Militaire 2nd Class.—Captain (Temporary) E. A. Harris, R.A.M.C.

The King of the Hellenes has conferred the decoration of Commander of the Royal Order of the Phoenix upon Colonel (Temporary) M. R. Burke, O.B.E., R.A.M.C., in recognition of distinguished services in the cause of the Allies.

The Queen of the Netherlands has conferred the decoration of Grand Officer of the Order of Orange Nassau with Swords upon Lieutenant-General Sir Alexander Hood, G.B.E., K.C.B., K.H.P., late R.A.M.C., in recognition of distinguished services in the cause of the Allies.

The King of the Hellenes has conferred the Distinguished Service Medal upon Colonel J. P. LaPlante, O.B.E., E.D., R.C.A.M.C., in recognition of distinguished services in the cause of the Allies.

In a Supplement to the *London Gazette* dated March 19, and in the *Journal of Norway* had conferred the King Haakon VII Liberty Cross upon Major (Temporary) J. N. MacArtney, M.B.E., R.A.M.C., in recognition of distinguished services in the cause of the Allies. This name should have read Major J. E. McCartney, R.A.M.C.

DEATHS IN THE SERVICES

Lieut-Col G. H. GODDARD, D.S.O., died on April 20 after a brief illness. Born in London in 1873, he was the son of Lieut-Col. Thomas Goddard, of the Indian Army. He was educated at University College School and University College Hospital, and took the conjoint diploma in 1895. He spent two years as surgeon to the British India Steam Navigation Company, followed by two years in resident posts at the Sheffield Royal Infirmary. He joined the R.A.M.C. in 1899 and served through the Boer War, gaining the Queen's Medal with three clasps, and the King's Medal with two clasps. He also served in France with the rank of lieutenant-colonel during the first world war, was awarded the D.S.O. and was four times mentioned in dispatches; he was gassed in 1916. Goddard acted as D.D.M.S. at Gibraltar in 1919, being invalided on pension in 1923. He was then given command of the Military Hospital at Norton Barracks, Worcester, and finally retired in 1943, though he still remained active as chairman of the local pensions board. He became a member of the British Medical Association in 1901, was chairman of the Worcester and Bromsgrove Division in 1936-7, and a representative at the Annual Representative Meeting in Plymouth in 1938; and he was appointed Local Emergency Officer in the same year. During his twenty-five years in Worcester he took part in many social and semi-public activities. He was also a Knight of Grace of the Venerable Order of St. John of Jerusalem in 1923, and for many years examined in first aid. He was twice vice-chairman of the Worcestershire Joint Committee of the Grand Cross and Order of St. John. He was a prominent Freemason, being a Past Grand Deacon of the United Grand Lodge of England, and Past Deputy District Grand Master of Gibraltari; he held high office in some of the higher degrees of Freemasonry. He was twice married, and leaves two sons by his first marriage, and a widow and one son of his second marriage. Colonel Goddard had a charming

and kindly personality and will be greatly missed in the City and County of Worcester, where many of his friends were accustomed to turn to him for sage counsel and advice, which was always readily given. A friend of his was heard to make a remark which sums up his character in a sentence: "I don't think he knew how to be unkind."

Universities and Colleges

UNIVERSITY OF OXFORD

In a Congregation held on April 29 the following degrees were conferred:

D.M.—D. L. Davies, *K. C. Royes
*In absence

UNIVERSITY OF LONDON

The appointment of members of the Senate for 1948-52 has been made as follows: *Faculty of Medicine*, Prof. R. V. Christie, M.D., D.Sc., F.R.C.P. (in place of Sir Francis Fraser, M.D., F.R.C.P.); *General Medical Schools*, E. R. Boland, M.D., F.R.C.P. (in place of Dr. A. E. Clark-Kennedy). Sir Francis Fraser has been co-opted as a member of the Senate.

The following have been elected to the Fellowship of University College, London: Sir Stewart Duke-Elder, K.C.V.O., D.Sc., M.D., Ph.D., F.R.C.S., Surgery-Oculist to the King; Marion Grace Eggleston, D.Sc., M.R.C.S., L.R.C.P., Senior Lecturer in Physiology in the College; William Arthur Edward Karunaratne, M.D., Professor of Pathology and Dean of the Faculty, Ceylon Medical College; Philippa Parry Martin, M.S., F.R.C.S., formerly Hunterian Professor of the Royal College of Surgeons of England.

The following have been elected to the Honorary Fellowship of University College, London: Sir Henry Hallett Dale, O.M., G.B.E., M.D., F.R.C.P., F.R.S., Chairman of the Wellcome Trust and formerly President of the Royal Society; and Archibald Vivian Hill, C.H., LL.D., Sc.D., Hon. M.D., F.R.S., Foulerton Professor of Physiology (Biophysics Research Unit) in the college.

C. Price Thomas, F.R.C.S., has been appointed representative of the University at the twelfth session of Les Journées Médicales de Bruxelles, June 13-16.

Ivor Lewis, M.D., and A. Talbot Rogers, M.B., B.S., have been elected members of the Standing Committee of Convocation for the period 1948-51.

The following have been recognized as Teachers of the University in the subjects indicated in parentheses: *University College Hospital Medical School*, E. Gwynne Thomas, M.D., M.R.C.P. (Venereal Diseases); *Royal Dental Hospital School of Dental Surgery*, M. P. Graham, M.R.C.S., L.R.C.P., L.D.S., H. L. Hardwick, M.R.C.S., F.R.C.P., L.D.S., and A. B. MacGregor, M.D., L.D.S. (Dental Surgery).

The M.B., B.S. examinations in October will start on Tuesday, Oct. 19, instead of Monday, Oct. 11.

The following clarification of the exemption regulations in medicine and amendment of the regulations relating to exemption of advanced students (external) in the Faculty of Medicine were published in the *University of London Gazette* dated March 27:

"Where exemption is normally granted in respect of intermediate or final examinations in other Faculties, the words 'of this University' are included, but in the case of medicine this is not so, and students who have passed what they consider equivalent examinations of other universities have claimed exemption under these regulations. The section headed 'Exemptions' in the regulations in medicine for external students have therefore been amended to make it clear that exemption is granted only in respect of intermediate and final examinations of this University."

The regulations relating to exemption of advanced students (external) in the Faculty of Medicine have been amended and now read as follows: "In the Faculty of Medicine exemption from the first examination for medical degrees, in whole or in part, and from the course of study for the second examination for medical degrees, in whole or in part, may be granted to students who have passed all the examinations for an approved degree of another university. No exemption can be granted from the second examination for medical degrees or from any part of the clinical course."

Applications are invited for the William Julius Mickle Fellowship, which is of the value of approximately £250, and is awarded by the Senate to the man or woman who, being resident in London and a graduate of the University, has in the opinion of the Senate done much to advance medical art or science within the preceding five years. Applications must be received by Oct. 1. Further particulars can be obtained from the Academic Registrar, Senate House, University College, W.C.1.

The following candidates have been approved at the examinations

Department of Medicine in Psychological Medicine.—With Mental Diseases
M. O. Luck, J. W. F. Lumsden, J. D. M. Lytle, Isabel M. Macrae, Margaret D. R. McDougall, P. J. McEnroy, A. A. McKirdy, A. D. MacLean, J. H. MacLoughlin, I. F. MacMath, Florence H. Macmichael, T. McG. McNie, D. MacVicar, J. J. Marlow, Barbara D. S. Marshall, R. H. Martin, Queenie I. E. May, Eva G. Maughan, J. I. Miller, Norah C. Miller, C. M. Meyer, A. P. B. Mitchell, A. B. Mirra, G. Morgan, N. Moss, Edith R. Munro, Alexina M. H. Myles, A. O. Nichols, W. P. O'Keefe, Mary D. Owen, J. L. Park, R. B. Parker, Jean Mc. Paterson, Noel J. Pease, J. H. Pendered, G. W. Pinder, J. H. McK. Pinkerton, H. P. Player, S. H. M. Price, J. Priceman, T. M. Pritchard, J. P. C. Purdon, Eleanor R. Raistrick, Angel M. Rendle-Short, J. C. A. Renshaw, P. Rhodes, Nancy M. E. Robertshaw, Ruth M. Roake, T. C. A. Roultoun, W. R. Russell, K. D. Salzmann, B. Sandler, H. I. Schmilg, J. W. F. Scrimgeour, T. O. Scudamore, E. H. Seward, Elsie M. Sibbings, S. A. Siddiki, A. Simons, E. M. Slater, A. L. H. Smith, Z. H. Y. Sobani, D. B. Spanton, Agnes M. Stark, Vera F. Stimson, R. A. Thatcher, C. J. Thornberry, R. W. H. Tincker, S. Tomlinson, G. E. E. Usher-Somers, C. Venables, F. L. A. Vernon, F. G. H. Warner, Margaret S. White, G. F. J. Williams, J. A. Williams, Marion Williams, T. A. Yates, E. J. Young-Thompson, E. G. Zaeks, O. Zammit.

UNIVERSITY OF ST. ANDREWS

Anthony Elliot Ritchie, M.D., has been appointed *Chandos Professor of Physiology* in the United College of the University.

UNIVERSITY OF SHEFFIELD

At a meeting of the University Council, held on May 21, John Colquhoun, M.B., Ch.B., was appointed Honorary Lecturer in Bacteriology.

The Council received the resignations of Mr. Glyn A. Davies, F.R.C.S.Ed., and Dr. V. Blackman of the posts of lecturer in obstetrics and gynaecology and demonstrator in anatomy, respectively, and thanked them for their services to the University.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

An ordinary meeting of the Council of the College was held on May 13, with Sir Alfred Webb-Johnson, Bt., President, in the chair.

A resolution of condolence was passed on the death of Prof. A. H. Burgess, the senior member of the Council.

The following hospitals were recognized in connexion with the regulations for the Final Fellowship examination: Victoria Hospital, Accrington (senior house-surgeon, provided that an additional resident surgical post is created); County Hospital, Farnborough (first, second, and third house-surgeons); Royal Cancer Hospital, London (resident medical officer, first and second house-surgeons); Canadian Red Cross Memorial Hospital, Taplow (resident surgical officer and first house-surgeon); General Hospital, Newcastle-upon-Tyne (resident surgical officer and two surgical registrars); County Hospital, York (additional recognition of the second house-surgeon).

A Diploma of Fellowship was granted to David Ronald Urquhart. Diplomas of Membership were granted to A. J. De Villiers, O. A. N. Husain, and Margaret N. A. Tew.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH

At a meeting of the Royal College of Surgeons of Edinburgh held on May 19, with Mr. Frank E. Jardine, President, in the chair, the following candidates, having passed the requisite examinations, were admitted Fellows: C. R. S. Davidson, E. O. Dawson, T. Don, D. MacL., Douglas, A. K. Dutt, H. D. Fairman, J. Fine, L. B. Gottlieb, K. S. Grewal, E. G. Hardy, G. D. Jack, Z. A. Karir, S. Kavanagh, H. G. Khalsa, I. S. Kirkland, J. M. Large, A. J. Leonsins, D. G. Lloyd-Davies, E. J. Marais, J. McE. Megaw, N. V. Mody, O. D. Morris, R. A. McCluskie, A. B. MacLean, J. A. Orr, K. Paw, H. N. Perkins, W. R. Phillips, M. C. Pinkerton, E. H. Rainer, P. M. Roemmele, A. K. Saha, A. I. Sahyoun, M. M. El Din Said, S. N. Sarma, O. J. Shah, W. D. Sharpe, B. J. Shaw, C. J. C. Smith, P. B. Sulakhe, R. Vaughan-Jones, O. Walshy, P. Wilson, L. E. Wood.

ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

Prof. N. C. Louros, professor of obstetrics and gynaecology in the University of Athens, will deliver a lecture on "Accelerated Painless Labour" at the College House (58, Queen Anne Street, London, W.1) on Friday, June 11, at 2.15 p.m. All members of the medical profession are invited to attend the lecture, admission to which is by ticket only, obtainable from the secretary, and allotted in order of application.

The following candidates have satisfied the examiners at the examination indicated:

DIPLOMA IN OBSTETRICS.—E. P. Abson, J. D. Andrew, Muriel S. Alexander, D. L. Arnold, P. B. Atkinson, P. Barron, J. P. Bennett, B. Bhattacharya, D. T. Binns, D. K. Black, D. H. Blakey, Winifred M. Bond, S. C. Bose, G. Bridge, Jean M. Briscoe, Joyce E. Brooks, H. J. S. Brown, R. A. Bush, J. Campbell, J. P. Carille, D. L. Carmichael, R. S. Casement, C. J. C. Smith, P. B. Sulakhe, R. Vaughan-Jones, O. Walshy, P. Wilson, L. E. Wood. Katharine M. D. Colman, Janet S. Conn, Mary C. J. Crabb, Evelyn M. Crawford, D. H. Crook, J. M. H. Dale, J. M. B. Donaldson, J. Dougall, G. H. P. Drake, C. D. Drea, Elisabeth A. Ede, L. El-Badri, C. C. Evill, M. B. Fox, W. D. Frew, H. Fried, C. O. Fung-Kee-Fung, Elizabeth Gilbertson, D. W. H. Griffiths, Lillian M. Griffiths, P. Haden, Ruth A. Haes, C. Halamandres, L. Haldar, G. J. Hall, J. R. A. Hall, Constance I. Ham, D. M. Hare, S. H. Heard, J. Henderson, T. Hepburn, Nancy Heron, J. D. S. Helicote, W. S. Hill, E. H. Hillyard, S. P. Hing, R. Hodgkinson, Flora M. Hogg, H. J. Holloway, T. A. Hope, P. W. Horner, H. Huichison, E. W. Ilangantileke, R. A. Irani, P. F. C. Jackson, Ruby Mc. Jackson, A. W. Kelly, G. L. Kennedy, H. H. Kirk, H. Korte, P. B. Lacy, F. Laverty, R. G. Law, Daisy J. Lee, R. E. Leighton, Jean B. Lindsay, R. H. Little, M. O. Luck, J. W. F. Lumsden, J. D. M. Lytle, Isabel M. Macrae, Margaret D. R. McDougall, P. J. McEnroy, A. A. McKirdy, A. D. MacLean, J. H. MacLoughlin, I. F. MacMath, Florence H. Macmichael, T. McG. McNie, D. MacVicar, J. J. Marlow, Barbara D. S. Marshall, R. H. Martin, Queenie I. E. May, Eva G. Maughan, J. I. Miller, Norah C. Miller, C. M. Meyer, A. P. B. Mitchell, A. B. Mirra, G. Morgan, N. Moss, Edith R. Munro, Alexina M. H. Myles, A. O. Nichols, W. P. O'Keefe, Mary D. Owen, J. L. Park, R. B. Parker, Jean Mc. Paterson, Noel J. Pease, J. H. Pendered, G. W. Pinder, J. H. McK. Pinkerton, H. P. Player, S. H. M. Price, J. Priceman, T. M. Pritchard, J. P. C. Purdon, Eleanor R. Raistrick, Angel M. Rendle-Short, J. C. A. Renshaw, P. Rhodes, Nancy M. E. Robertshaw, Ruth M. Roake, T. C. A. Roultoun, W. R. Russell, K. D. Salzmann, B. Sandler, H. I. Schmilg, J. W. F. Scrimgeour, T. O. Scudamore, E. H. Seward, Elsie M. Sibbings, S. A. Siddiki, A. Simons, E. M. Slater, A. L. H. Smith, Z. H. Y. Sobani, D. B. Spanton, Agnes M. Stark, Vera F. Stimson, R. A. Thatcher, C. J. Thornberry, R. W. H. Tincker, S. Tomlinson, G. E. E. Usher-Somers, C. Venables, F. L. A. Vernon, F. G. H. Warner, Margaret S. White, G. F. J. Williams, J. A. Williams, Marion Williams, T. A. Yates, E. J. Young-Thompson, E. G. Zaeks, O. Zammit.

No. 19

INFECTIOUS DISEASES AND VITAL STATISTICS

The print below a summary of Infectious Diseases and Vital statistics in the British Isles during the week ended May 8.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland. *Figures of Birth and Deaths, and of Deaths recorded under each infectious disease, for:* (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland. A dash — denotes no cases, a blank space denotes disease not notifiable or return available.

Disease	1948					1947 (Corresponding Week)

† Includes puerperal fever for England and Wales and Eire.

EPIDEMIOLOGICAL NOTES

Discussion of Table

In England and Wales the only fluctuations in the trends of infectious diseases were decreases in the incidence of whooping-cough 574 and acute pneumonia 37 and an increase in the notifications of scarlet fever 40.

A fall in the number of notifications of whooping-cough occurred throughout the country: the largest decreases were Yorkshire West Riding 89 and Warwickshire 72. Although the total for measles remained practically unchanged there were considerable local variations in incidence: the rises included Middlesex 146, Kent 69, Denbigh 67, and the largest decreases were London 165, Surrey 142, Hertfordshire 74.

A rise of 16 in Lancashire provided the chief feature of the returns of diphtheria. Only small variations occurred in the incidence of scarlet fever; the largest were a decrease of 24 in Yorkshire West Riding and a rise of 28 in Lancashire. An increase of 24 in the notifications of acute pneumonia in Durham was the only fluctuation of any size in the local incidence of this disease.

A fresh outbreak of dysentery, involving 10 persons, was reported for Bedfordshire, Luton M.B. The other large returns of dysentery were London 28, Lancashire 27 and Yorkshire West Riding 12. Of the 9 cases of poliomyelitis, 3 were notified in Manchester C.B.

In Scotland infectious diseases were slightly less prevalent during the week: the decreases included measles 24, scarlet fever 10, acute primary pneumonia 10 and dysentery 2. No disease showed an increase in incidence. The largest returns for dysentery were those of the cities of Glasgow 28 and of Edinburgh 11.

In Eire only small changes occurred in the trends of infectious diseases. An outbreak of measles affecting 22 persons was notified from Wexford U.D.

In Northern Ireland the chief feature of the returns was an increase of 28 in the notifications of measles in Belfast C.B.

Week Ending May 15

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,675, whooping-cough 3,117, diphtheria 153, measles 11,879, acute pneumonia 611, cerebrospinal fever 36, acute poliomyelitis 19, dysentery 111, scarlatina fever and typhoid 6.

Medical News

Assistant Secretary for B.M.A.

The Council of the B.M.A. is advertising in this issue of the *Journal* (p. 13) for an Assistant Secretary. He will work at first at Headquarters, but may later be transferred to a regional office. The salary is £1,250 a year, rising to £1,875. Medical practitioners, including those serving with the Forces, are invited to apply.

Recruitment and Training of Nurses

The Medical Women's Federation has submitted to the Minister of Health a memorandum on the Report of the Working Party on the Recruitment and Training of Nurses. The Federation emphasizes that the craft of bedside nursing should be revived: nursing should be a relationship not unlike that between mother and child. It doubts whether the two years' course suggested by the Working Party is sufficiently long in which to train nurses, and it would like to see experiments made on methods of training nurses to think along social and preventive lines. The present training is overloaded with theory. The Federation considers also that the Working Party's criteria of selection make too heavy intellectual demands on girls who may not be clever but who have a natural aptitude for bedside nursing; their rejection would be a serious loss to the sick of this country. The present examinations are much too difficult and the standard of marking too low. The Federation proposes an intermediate grade of "hospital nurse" for those who have successfully completed two years' training at the bedside but who are not accepted for the senior course leading to State registration.

Chair of Child Health at Belfast

An endowment of £60,000 has recently been received by the Queen's University of Belfast in order to found a chair and department of child health at the University. This contribution to the teaching and improvement of paediatrics in the Province has been made equally by the Government of Northern Ireland and by the Nuffield Provincial Hospitals Trust through the Northern Ireland Regional Hospitals Council.

Ice-cream Control

From Nov. 1 the manufacture of ice-cream in Scotland will be controlled by Regulation. It will be unlawful to make, store, or sell ice-cream except on premises licensed by the local authority; vehicles selling it must also be registered. Boarding houses, clubs, hotels, and inns are exempt from registration, as also are restaurants where ice-cream is sold only as part of a meal and theatres and cinemas where it is not made on the premises. The local authority must be satisfied about the cleanliness of the staff and the suitability of the equipment in the factories or shops concerned.

Scholarship for Nurses

The King Edward's Hospital Fund for London is offering under the auspices of the National Florence Nightingale Memorial Committee a £350 scholarship to trained nurses on the staff of hospitals in the Fund's area or returning to such posts. The scholarship is for one of the courses arranged by the Florence Nightingale International Foundation, which may be taken in different branches of nursing and in various countries. Candidates should have had a general education to matriculation standard and several years' experience in general nursing after State registration. Application forms, which may be sent in up till June 14, may be obtained from the Secretary, Nursing Recruitment Service (King Edward's Hospital Fund), 21, Cavendish Square, London, W.1.

Rebuilding St. Thomas's Hospital

St Thomas's Hospital plans eventually to have nearly 1,000 beds, in accordance with the Goodenough Committee's recommendations. The Secretary's report was presented recently to the Court of Governors and outlined the schemes for reconstruction. A new medical school and students' accommodation will be grouped with the hospital and new accommodation for nurses and staff will also be provided.

American Association of Plastic Surgeons

Prof. T. Pomfret Kilner, President of the British Association of Plastic Surgeons, has accepted an invitation to attend the annual meeting of the American Association of Plastic Surgeons in Boston in June. He will take the opportunity of visiting other centres.

Egyptian Ophthalmologist's Visit

Dr. Mahmoud Azmy el Kattan Bey, Professor of Ophthalmology and Dean of the Faculty of Medicine in Demerdashe Hospital, Cairo, who was a medical student in Britain from 1921 to 1923, is now studying undergraduate and postgraduate teaching in British hospitals at the invitation of the British Council. He will return to Cairo on June 14.

COMING EVENTS**The Nation's Nurses**

A conference on "The Nation's Nurses" will be held at the Royal College of Nursing, Henrietta Place, Cavendish Square, London, W.1, on Monday, Tuesday, and Wednesday, May 31 and June 1 and 2, when there will be discussions on modern planning, equipment, and methods designed to improve the service to the patients. The conference will open on May 31, at 10.15 a.m., with an address by the chairman, Mr. Harold Hunter, deputy director of the Bureau of Current Affairs, and on June 2, at 2.45 p.m., the Minister of Health, the Rt. Hon. Aneurin Bevan, will deliver an address. In addition to members of the college, members and representatives of many of the regional hospital boards will attend the conference, admission to which is, by programme, obtainable from the general secretary of the college at the above address.

Safer Motherhood

A public meeting and brains trust on "Safer Motherhood," arranged under the auspices of the Married Women's Association, the National Birthday Trust Fund, and the National Federation of Women's Institutes, will be held at Caxton Hall, Westminster, London, S.W., on Tuesday, June 8, at 7 p.m. The speaker will be Sir Lindley Holland, M.D., F.R.C.P., F.R.C.S., F.R.C.O.G., and the question master Dr. Charles Hill, Secretary of the British Medical Association. The brains trust will comprise Sir Eardley Holland, M.D., Josephine Barnes, D.M., F.R.C.S., Lady Rhys-Williams, D.B.E., Mrs. G. B. Carter, B.Sc., S.R.N., S.C.M., and Dr. Geoffrey S. W. Ogden, D.A. The chair will be taken by Lady Helen Nutting, President of the Married Women's Association. A senior medical officer will be present to represent the Minister of Health. Tickets may be obtained from the meeting secretary, Safer Motherhood Committee, 57, Lower Belgrave Street, London, S.W.1.

Rheumatism Conference

A Satellite Conference on "Le Rhumatisme Chronique" at Anderlecht will be held on June 24-27. Particulars may be obtained from Dr. Gerbay, 7, Square Alfred-Boucher,

Medical Superintendents' Society

The annual general meeting of the Medical Superintendents' Society will be held at the Royal Hospital for Sick Children, Glasgow, on Thursday, June 3, at 10.30 a.m., when Dr. H. Stanley Banks will be installed as president. The annual dinner of the society will be held at the Central Station Hotel, Glasgow, on Friday, June 4, at 7.30 p.m., when the guest of honour will be the Rt. Hon. Walter E. Elliot, M.P.

Empire Rheumatism Council

A summer week-end course, arranged by the Empire Rheumatism Council, Tavistock House (N), Tavistock Square, London, W.C., will be held at the Apothecaries' Hall, Black Friars' Lane, Queen Victoria Street, London, E.C., on Saturday and Sunday, June 12 and 13, with the following programme: June 12, 10 a.m., "Rheumatism—A Clinical Survey," by Prof. Henry Cohen; 11.15, "Gout," by Dr. George Graham; 2 p.m., "Neuritis," by Dr. E. Fletcher; 3 p.m., "Fibrositis," by Dr. W. S. C. Copeman; 4.30, "Spondylitis," by Dr. W. S. Tegner. June 13, 10 a.m., "Physiotherapy in the Treatment of the Rheumatic Diseases," by Dr. Cooksey; 11.15 a.m., "Orthopaedic Aspects of the Rheumatic Diseases," by Mr. J. C. R. Hindenach. The fee for the course is £1 ls., and entries, limited to 100, must be received with remittance at least one week before, by the General Secretary of the Council at the above address.

Ross Jubilee, 1898-1948

A reception, arranged by the Ross Institute of Tropical Hygiene, will be held at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C., on Monday, July 5, at 5 p.m. to celebrate the discovery of the route of transmission of malarial fever by Sir Ronald Ross in July, 1898. At 6.30 p.m., in the lecture theatre, Dr. John Masefield, the Poet Laureate, will speak "Ronald Ross." An exhibit showing the progress made in the control of malaria over a period of fifty years will be on display in the museum from 5 p.m. to 8 p.m., and will be open to the public from 11 a.m. to 3 p.m., from July 6 to 9 inclusive. Refreshments will be served in the library, the senior common room, and the marquee over the lecture theatre from 5 p.m. to 8 p.m.

Oxford Graduates' Medical Club

The summer dinner of the Oxford Graduates' Medical Club will be held at Christ Church, Oxford, on Friday, July 16, at 7.30 p.m., when the chair will be taken by Prof. A. W. M. D.M., F.R.C.P. All men who are Oxford graduates, studying or practising medicine, are members of the club and it is hoped there will be a good attendance at this, the first post-war dinner. Accommodation is restricted, making it impossible to allow more than 100 on this occasion. The joint honorary secretary of the club, Mr. E. A. Crook, M.Ch., F.R.C.S. (149, Harley Street, London, W.1), asks those who intend to be present at the dinner to let him know by July 1 at the latest; he would also be glad of the permanent addresses of all members. The cost of the dinner is 30s., incl. of wine, and day dress will be worn.

International Congress of Physical Education, Recreation, and Rehabilitation

The organizing committee of the International Congress of Physical Education, Recreation, and Rehabilitation, which is held in London from July 23-26 under the auspices of the Ministry of Education, is now prepared to consider applications from delegates and educationists who wish to attend in their personal capacity. The aim of the congress is to give some indication of the steps taken in Britain to develop physical education in schools, colleges, physical recreation in after-school life, and rehabilitation in industry and in the Services, and to provide an opportunity for a world-wide exchange of information and ideas about these matters. The Minister of Education has kindly consented to open the congress, and the closing address will be given by Prof. Arthur N. S. Wells known for his work in the field of international relations. Fifty foreign countries, Dominions, and Colonies have already decided to send delegates, and invitations have also been extended to a number of British organizations concerned with education, medicine, and social welfare. The fee for the whole congress is 10s. but in certain circumstances it may be possible to accept applications for attendance at one session (morning or afternoon) on payment of 5s. As accommodation is limited, those interested are asked to write as soon as possible to the general secretary of the Congress, 6, Bedford Square, London, W.C.1, who will be glad to send a draft programme and the application form which should be completed by those who wish to attend.

Anthropology and Ethnology

The 3rd Session of the International Congress of Anthropology and Ethnological Sciences will be held in Brussels and Tervuren on Aug. 15-23, under the Presidency of Prof. E. De Jonghe. Particulars may be obtained from the Secretary, Frans M. Olb, Musée du Congo Belge, Tervuren, Belgium.

SOCIETIES AND LECTURES

Monday

EDINBURGH UNIVERSITY: PHYSIOLOGY CLASSROOM.—May 31, 5 p.m. "John Hunter: Surgeon and Naturalist," by Dr. Douglas Guthrie.
UNIVERSITY COLLEGE LONDON.—At Anatomy Theatre, Gower Street, W.C., May 31, 5.30 p.m. Shearman Lecture: "The Origin and Nature of Scientific Thought," by Mr. E. Schrödinger, Ph.D., D.Sc.

Tuesday

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—June 1, 5 p.m. "Varicose Eczema, Ulceration etc.," by Mr. A. K. Monro.

Thursday

FACULTY OF HOMOEOPATHY.—At London Homoeopathic Hospital, Great Ormond Street, London, W.C., June 3, 5 p.m. "Notes on Worm Infestation in Children," by Dr. Elizabeth M. J. Paterson.
INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—June 3, 5 p.m. "Eczema," by Dr. G. B. Mitchell-Heggs.

SOCIETY AND CLINIC FOR CONSTRUCTIVE BIRTH CONTROL AND RACIAL PROGRESS, 106, Whitfield Street, Tottenham Court Road, London, W.—June 3, 2.30 p.m. "Practical demonstration of contraceptive methods," by Drs. Marie Stopes and Beddow Bayly.

SOCIETY OF APOTHECARIES OF LONDON, Apothecaries' Hall, Black Friars Lane, Queen Victoria Street, E.C., June 3, 5 p.m. "The Pharmacology of Heart Failure," Joseph Strickland Goodall Memorial Lecture by Prof. John McMichael, M.D., F.R.C.P.Ed.
UNIVERSITY COLLEGE LONDON: DEPARTMENT OF PHARMACOLOGY.—At Physiology Theatre, Gower Street, London, W.C., June 3, 5.15 p.m. "The Action of Drugs on Mitosis," by Mr. J. F. Danielli, Ph.D., D.Sc.

APPOINTMENTS

D. Manuel Suarez has been appointed Professor of Paediatrics, Faculty of Medicine at San Diego de Compostella, Spain.

Dr. Cluni Lal Katil has been appointed Director-General of the Employees State Health Insurance Corporation of the Dominion of India.

Dr. Katil came to England and entered general practice at Finsbury 22 years ago and has played an active part in the medical services and the public health organisation of the borough. He was mayor for 1938-9 and was raised to the Aldermanic Bench in 1945. He was elected to the L.C.C. as a representative of the borough at the last elections. In his new appointment he will organize a health insurance scheme which will include a comprehensive medical service.

ORCHARD, W. E., M.D., D.P.H., Deputy Senior Administrative Medical Officer, Sheffield Regional Hospital Board.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Bourke.—On April 29, 1948, to Joan, wife of E. E. Bourke, F.R.C.S. (obstet.), Supt., London, W., a son.
Brash.—On May 15, 1948, at Stobhill Hospital, Glasgow, to Patricia (nee Park), wife of David Brash, M.B., Ch.B., D.M.R., a son—David Lawrence Powell-Tuck.—On May 20, 1948, at The Crossways, Acocks Green, Birmingham, to Catherine (nee Kirby) wife of Dr. G. A. Powell-Tuck, a son.
Widkinson.—On May 8, 1948, at Watford, to Kathleen, wife of Dr. R. H. Widkinson, a son—Andrew Richard.

MARRIAGE

Mather—Buchanan.—On April 21, 1948, at Edinburgh, John Stewart Mather, M.B., Ch.B., of Bradford, to Maud Lovett Buchanan, M.B., Ch.B., of Edinburgh.

DEATHS

Blacket.—On May 21, 1948, at Oak Hill Cottage, Frensham, Surrey, Sir George Francis Blacket, C.B.E., M.D., F.R.C.P., F.R.C.S.
Blackett.—On May 13, 1948, in London, Edward Joseph Blackett, O.B.E., M.R.C.S., L.R.C.P., of 20 Kendal Street, London, W., aged 77.
Chambers.—On May 19, 1948, at Treflus, Yealming, S. Devon, Gerald Chambers, M.B., Ch.B., D.M.R.E.
Conford.—On May 15, 1948, at 20, Bath Road, Felixstowe, George James Conford, M.D., aged 78.
Fraser.—Recently in South Africa, James Fraser, M.B., Ch.B. Glas.
Gwynne-Hughes.—On Feb. 8, 1948, Devereux Gwynne-Hughes, F.R.C.S. Ed. of New South Wales, Australia, aged 87.
Hall.—On May 17, 1948, Peter Sinclair Hall, M.B., B.Chir., of Sparrows Searle Road, Farnham, aged 28.
Linton.—On May 18, 1948, at The Acorn, Swain Road, Tenterden, Kent, William West Linton, F.R.C.S., aged 76.
MacGillchrist.—On May 14, 1948, at 9, Mandeville Gardens, Ballygunn, Calcutta, India, Archibald Currie MacGillchrist, M.D. Ed., D.Sc., M.R.C.P., Colonel, I.M.S., retired.
MacVean.—On May 13, 1948, at Blair House, Kirkcudbright, John MacVean, M.D., C.M.E., aged 85.
Metcalfe.—Suddenly, at Moorside North, Newcastle, Stanley Dunn Metcalfe, M.B., B.S., aged 63.
Miller.—On May 17, 1948, at Haslinges, Arthur William Miller, M.B., C.M.Glas., aged 80.
Muldaavin.—On April 24, 1948, Léon Feinsein Muldaavin, M.D., of New York, aged 37.
Ollerenshaw.—On May 19, 1948, suddenly, Robert Ollerenshaw, M.D., F.R.C.S., of Broome House, Didbury, Manchester.
Pole.—On May 21, 1948, at 13, Cameron Park, Edinburgh, Laurence William Pole, M.B., Ch.B. Ed., D.P.H., aged 72.
Renton.—On May 19, 1948, Maurice Waugh Renton, M.D., D.P.H., of the Bridge House, Darford, Kent.
Taylor-Young.—On May 20, 1948, at a Salisbury Nursing Home, Hugh Corbett Taylor-Young, O.B.E., M.D., F.R.F.P.S. Glas., formerly of Sydney, N.S.W.
Watson.—Dunne Augustin, retired, Edward Clifford Watson, D.S.O., M.R.C.S., L.R.C.P., Captain, R.N., aged 74.
Watts.—On May 14, 1948, at St Mary's Hospital, London, W., Brian Watts, D.S.O., M.D. Brux., Colonel, R.A.M.C., retired.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Legal Ownership of X-ray Films

Q.—Who is the legal owner of x-ray films? Do they remain the property of the radiologist? How should I respond to a request from the patient of a colleague of mine for copies of films which are wanted to help him in a legal action against another doctor?

A.—The question, "Who is the legal owner of x-ray films?" has never been finally settled. It is discussed at length, with many illustrative case references, by D. Harcourt Kitchin in his *Legal Problems in Medical Practice* (1936, pp. 127-30), and it was also the subject of an article which appeared in the *Journal* of Jan. 13, 1934 (p. 80). It is generally agreed from the medical point of view that the films belong to the radiologist; they are an indispensable part of the material on which he founds his opinion. If the patient pays him a fee, this is in respect of his opinion, and not in consideration of the handing over of the films. If the films are so handed over and the radiologist is afterwards sued for giving a negligent opinion, he would be unable to defend his interpretation of the films unless they were handed back to him. The German Röntgen Society issued a declaration in 1912 to the effect that it considered that all films, prints, diagrams, tracings, etc., prepared by the radiologist were to be regarded as his property, just as the histological preparations of a consulting pathologist remain his property, on which he bases his opinion of the nature of the material submitted to him for examination. The practitioner who refers the case to the radiologist is entitled, as a matter of courtesy, to inspect the films.

There are several decisions in American courts (quoted by Kitchin) which go to show that the x-ray films are the property of the radiologist or of the hospital in which such an examination has been made and that it is just as necessary that the film should be retained by the practitioner in charge of the case as that he should preserve the temperature charts and other case records. In determining any question of ownership of the film the court has regard to the nature of the contract, and will not, generally speaking, infer without express evidence that there is any contract to hand over the films to the patient who pays his fees for expert advice and not for the documents or other material on which that advice is based.

With regard to the second part of the question, this does not make quite clear the circumstances of the case; assuming that the questioner took the films in the course of the examination of the patient, who paid a fee for this service, the patient is entitled only to a copy of the radiologist's opinion; there would be no objection to the radiologist supplying copies of the films if he feels so disposed, but he is not bound to do so unless an order for disclosure is made by the court.

Stilboestrol for Acne

Q.—Does stilboestrol have any effect on the endocrine system of the male? It is often successful in alleviating acne vulgaris in the female. Would it be suitable for a male adolescent suffering from the same complaint?

A.—Stilboestrol acts in the male by inhibiting the gonadotrophic function of the pituitary gland, thus causing involution of the testicle and diminution or cessation of the secretion of testosterone. Since acne vulgaris in the male is believed to be linked with the secretion of testosterone, and since testosterone therapy, both in the male and the female, may produce acne, it might be expected that stilboestrol in sufficient doses would alleviate acne in the male. Clearly, however, it is not a measure that could be continued for any length of time in the male in the doses required. As to smaller doses, there is less definite evidence of some direct counteraction of testosterone by oestrogens. Of course it is known that acne may occur at puberty and adolescence in females as well as in males, and

sometimes in the treatment of amenorrhoea by stilboestrol acne is produced. On the whole the treatment of acne in the male by stilboestrol is disappointing, but some good results have been recorded.

Disseminated Sclerosis and Swayback in Sheep

Q.—Has the discovery of the association of disseminated sclerosis with swayback in sheep, described in the *Journal* of Sept. 20, 1947 (p. 460), led to any modification in treatment? Does any treatment influence the course of the disease?

A.—The discovery of the association of disseminated sclerosis with swayback in sheep has not yet led to any rational form of curative treatment of the disease. The situation is, briefly, that swayback is a disease which occurs in newborn lambs, the animals becoming progressively ataxic and dying within a short while. The condition arises only in offspring of ewes which have been fed on a copper-deficient diet, and the addition of copper to that diet will greatly reduce the incidence of the disease.

It is clear from the evidence, however, that a maternal copper deficiency is not the only cause, and the fact that several workers developed disseminated sclerosis suggested that there may also be an infective agent responsible in the predisposed animals. Much more work will be needed before these observations can be applied to the prevention and cure of the disease in man. There is no known method of treatment that will arrest disseminated sclerosis but much can be done to help the patient. First, rest during the acute exacerbation seems to reduce the severity to some extent; secondly, re-education with Frankel's exercises reduces the residual disorder of function; and, lastly, the judicious use of a placebo, together with superficial psychotherapy, maintains the patient's hopeful attitude throughout most of the illness.

Convalescent Measles Serum

Q.—Is there any method of ensuring that convalescent measles serum will not give rise to homologous serum jaundice?

A.—One of the dangers of using convalescent measles serum in children is the possibility of causing homologous serum jaundice. Cases of this condition due to the use of pooled convalescent measles serum appeared in 1937 and are referred to by McNulty (Report of the Chief Medical Officer, Ministry of Health, 1938). At present no way is known of destroying the causal virus without also destroying the measles immune bodies. Other less serious risks were discussed in a recent question and answer (May 15, p. 963).

Administration of Oxygen

Q. Under what circumstances can oxygen be bubbled through water before administration?

A.—Oxygen may always be bubbled through water before inhalation. It was formerly thought that this method of administration caused less dryness of the nasopharynx, and most of the older flowmeters were constructed on a principle embodying the passage of the gas through water. It is seldom done at the present time, and patients do not complain of dryness of the nasopharynx. The older water flowmeters were inaccurate, and when an adequate volume of oxygen per minute was administered such commotion resulted in the water as to make the method impracticable.

Treatment of Orbital Gumma

Q.—For the treatment of a man aged 51 with an orbital gumma (inner canthus of eye), and Wassermann reaction and Kahn test strongly positive, I have been advised that pot. iod. with hydrarg. perchlor. is all that is necessary, provided that it is taken for at least two years. Is any more active treatment demanded or necessary?

A.—The answer to the question is in the affirmative. The treatment advised might have been considered suitable forty years ago, but there seems no adequate reason to deny the benefit of modern powerful remedies. It might be a good idea to obtain the opinion of an ophthalmologist on whether resolution of the lesion would have any harmful

effects, in which case preliminary treatment with iodides, big muth, or very small doses of penicillin (e.g., 500 units) would be advisable. Otherwise the patient should receive a course of at least 6,000,000 units of penicillin, followed by a course of neoarsphenamine (5–6 g.) and bismuth (2–2.5 g.) over a period of about nine weeks. Thereafter, in view of the age of the patient, it might be wise to rely mainly on bismuth, but several courses should be given at suitable intervals as an insurance against further damage, though it is likely that the serum reactions will be difficult to reverse; too much importance should not be attached to the achievement of a negative serum reaction.

Distance between Cervix Uteri and Perineum

Q.—Has anyone else measured the difference in the distance between the cervix and the perineum in the upright position, the lithotomy position, and in the squatting position? I have found a difference of 1½ in. (1.25 cm.) between the first and third positions, and probably it is greater in the pregnant woman.

A.—Without searching the literature the writer does not know of any published work dealing with accurate measurements of the variations in distance between the cervix and perineum in the same woman. The supports of the uterus allow it a good deal of movement, so its position varies with the intra-abdominal pressure, the fullness of the bladder and rectum, and with posture. The degree of vertical movement also varies considerably in different individuals according to the laxity of the supports, the length of the vagina, etc. These are everyday clinical observations that are well known, and the effect of posture is recognized in practice by the use of the genu-pectoral and other special positions for gynaecological examinations and operations. It is to be expected that the squatting position will result in all the pelvic organs being crowded lower down, so that the distance between cervix and perineum will be correspondingly decreased.

Pregnancy and Psoriasis

Q.—What is the effect of pregnancy on psoriasis? What is the effect of the hormones present in pregnancy on psoriasis? I have a patient aged 27 who has had psoriasis since the age of 11. She has had three children, and on each occasion the rash began to recede about a month after conception and cleared up within one to two months after delivery, when it started to return.

A.—As with most other constitutional reactions, the effect of psychological, hormonal, and other disturbances in relation to psoriasis is well recognized. The onset during pubertal or menopausal years is one evidence of this, and it is common for pregnancy to have a beneficial effect on the course of psoriasis, though sometimes the reverse is true. The administration of hormones based upon this experience has often been tried but without any consistent results.

NOTES AND COMMENTS

Phosphaturia.—Dr. D. O'DONOVAN (Durban, South Africa) writes with reference to the question and answer under the heading "Phosphaturia and Oxaluria" ("Any Questions?" Feb. 28, p. 420) from personal experience and after an extended trial of the usual recommended means I have found that three to four "enemas" (Lilly) of ammonium chloride, 7½ gr. (0.5 g.), taken daily in divided doses will prevent phosphaturia and will allow the patient to lead a normal comfortable life. I have taken these tablets for several years without any ill effects.

All communications with regard to editorial business should be addressed to the EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: "Any Questions?" WESTEND, LONDON. ORIGINAL ARTICLES AND LETTERS forwarded for consideration are understood to be offered to the *British Medical Journal* and unless the contrary be stated. Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors overseas should indicate on MSS. if reprints are required, as proofs are not sent abroad. ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 2111. TELEGRAMS: "Britmedads, Westend, London." MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY, BRITISH MEDICAL ASSOCIATION, TELEPHONE: EUSTON 2111. TELEGRAMS: "Medisecra, London." NATIONAL HEALTH SERVICE ACT

(Continuation of para. 12 of Annual Report)

162 On April 7 the Minister of Health on behalf of the Government made a statement in the House of Commons on the National Health Service in the course of which he undertook to introduce an Amending Bill in which there would be included a provision to make it impossible for a whole-time service to be introduced by Regulation alone. At the same time the Minister announced that the proposed universal salary would be abandoned and replaced by:

- (1) An option for all principals in established practice who enter the new Service to receive their remuneration by capitation fees only, or by a fixed element of £300 per annum plus a lower proportionate rate of capitation;
- (2) a fixed element of £300 per annum for all new entrants in general practice, to be payable for the first three years, after which the practitioner would have the right to exercise the option accorded to existing principals.

On April 8 the Minister announced that he had appointed a committee of legal experts to examine partnership problems and advise him whether the National Health Service Act "ought to be amended to secure an equitable result between partners in medical practice." The proposed Amending Bill will be introduced when the report of the legal committee is available.

With a view to clarifying the position arising from the Minister's statement a number of questions were put to him by the Association. The questions and the Minister's replies were published in the *British Medical Journal* of April 17. The Council decided to hold a further plebiscite in order that it might be in a position fairly to judge the effect of the proposed pending legislation on the profession's opinions and intentions. On April 19 there were issued to every member of the profession in England, Wales, and Scotland with the plebiscite form

(1) The Minister's statements in the House of Commons on April 7 and 8, the Association's questions, and the Minister's replies;

(2) a statement by the Council embodying a factual analysis of the position, and expressing the opinion that, while progress had been made to that end, the freedoms of the profession were not sufficiently safeguarded. The Council urged individual members of the profession to determine their attitude on all the facts before them as they had determined their attitude on the facts before February.

The plebiscite form indicated that if in the aggregate the votes of consultants and specialists, general practitioners, and whole-time voluntary hospital staffs showed a majority against accepting service under the Acts, and this majority included approximately 13,000 general practitioners (out of a present total general-practitioner strength of 20,500), the Association would continue to advise the profession not to enter the Service.

The April plebiscite form was sent to 54,667 practitioners, of whom 40,622 voted. Under Section A, directed to the whole profession, 23,842 expressed disapproval of the National Health Service Acts, and 14,620 approved. Under Section B, addressed to consultants, general practitioners, and whole-time voluntary hospital staffs, of the 26,690 who voted, 13,981 were not in favour of accepting service under the Acts. This majority included 9,588 general practitioners. The February plebiscite showed that 17,037 general practitioners were against accepting service.

At its meeting on May 5 the Council considered the plebiscite results and received a letter from the Ministry of Health inviting the Association to appoint representatives to begin discussions as soon as possible on the details of the proposed Amending Bill and on other matters still outstanding. The Council decided to accept the Minister's invitation and to draw his attention to the large section of the profession which was still opposed to the Service and whose good will was essential if the Service was to succeed. The Council decided also that a report of the discussions with the Minister should be made to a Special Meeting of the Representative Body to be held on Friday, May 28. At the same meeting the Council passed the following recommendations for consideration by the Representative Body:

(a) That, despite the insufficiency of the safeguards to the profession's freedoms and the misgivings of a substantial section of the profession, the Representative Body, anxious as ever that in the public interest a comprehensive health service should be made available to the community, is prepared to advise the profession to co-operate in the new Service on the understanding that the Minister will continue negotiations on outstanding matters, including terms and conditions of service for consultants and specialists, general practitioners, public health officers, and others.

(b) That the Representative Body urges the profession to maintain its strength and unity in order to mould the Service in accordance with the public interest and with enlightened professional opinion and continuously to protect the profession's legitimate freedoms and interests.

(c) That the public be informed that, for reasons outside the control of the profession, the inception of the new Service cannot be followed for some time by all the improvements promised by the Government in the medical services of the country, because of the shortage of personnel, medical and nursing, and of the difficulty of providing the necessary premises and equipment.

GENERAL PRACTICE

Certification under the National Health Service Act

(Continuation of para. 34 of Annual Report)

163. The Council has now prepared the following statement of Evidence for submission to the Departmental Committee on Medical Certification. It is hoped, at a later date, to amplify the Statement by the submission of oral evidence to the Departmental Committee.

Introductory

In recent years the number and variety of purposes for which medical practitioners, and particularly those in general practice, are required to issue medical certificates have increased to an alarming degree. For this reason the Association views with concern the provisions of Sect. 33 (2) (d) of the National Health Service Act which empower the Minister of Health to make Regulations requiring practitioners providing service under the Act to issue to patients or their personal representatives certificates reasonably required by them under or for the purpose of any enactment. It therefore welcomes the appointment of a Departmental Committee by the Minister with the following terms of reference:

"To consider the medical certificates required under present enactments or Regulations—or for other administrative purposes—and to advise, without excluding the possibility of amending legislation, how far it would be practicable to reduce the number of certificates to be signed by medical practitioners, and to improve and simplify the forms of certificate and the rules governing their issue."

Scope of the Problem

The following is a classified list, not exhaustive, of certificates which general practitioners are commonly requested to give at the present time:

Group I—Statements regarding the condition of a patient with or without an expression of opinion as to immediate fitness for work, school, travel, attendance at court, etc.: (1) In support of claims to sickness benefit under the National Health Insurance Act, 1936. (2) In support of claims to additional benefit under the National Health Insurance Acts—e.g., dental or ophthalmic benefit. (3) In support of applications to Approved Societies for convalescent treatment. (4) In support of claims for sickness benefit under private arrangements—e.g., through sick club or insurance policy. (5) Evidence of unfitness for work through sickness required by an employer, whether Government or private. (6) Notification of infectious diseases under the Public Health Act, 1936. (7) Notification of industrial diseases under the Factories Act, 1937. (8) Certificate of unfitness to attend court. (9) Certificate of unfitness to travel, issued to a Service man taken sick while on leave. (10) Certificate of unfitness for school. (11) Certificate of fitness to attend a day nursery.

Group II—Statements in support of a patient's application for some concession, provision, exemption, or for some commodity in short supply: (1) Under the Blind Persons Acts, 1920 to 1938, to support an application for old age pension at 50. (2) Recommendation that child should attend special school. (3) In support of application to obtain baby foods without attendance at clinic. (4) Under the Essential Works Orders, Control of Employment (Directed Persons) Order, 1943, and Control of Engagement Orders in support of a claim to leave or change the employment. (5) Under the Road Haulage Wages Act, 1938, the Catering Wages Act, 1943, and the Wages Council Act, 1945, in support of a permit to be placed at sub-standard wage rates. (6) Under the Coal Distribution Order, 1943, and the Control of Fuel (Restriction of Heating) Order, 1947, to obtain additional supplies of fuel and exemption from rationing restrictions. (7) Under the Corsets (Manufacture and Sale) (No. 14) Directions, 1946, to assist in obtaining surgical corsets. (8) Under the Welfare Foods Order, 1946, to enable mothers to obtain food benefit. (9) Under the Rationing (Supplementary Rationed Food) and to assist invalids, expectant mothers, and others to obtain special treatment with regard to goods and services of Government control. (10) Under the Control of Motor Fuel Orders to assist claimants for additional supplies of motor fuel on medical grounds. (11) Under the National

Service Acts, 1939-47, in support of a claim for exemption from, and to justify failure to comply with, provision of the Act. (12) Certificates in support of application for exemption from jury service. (13) Certificate to obtain a vacuum flask.

Group III—Certain special certificates: (1) Under the Births and Deaths Registration Acts, 1836-1926—e.g., to certify cause of death to the Registrar. (2) Notification of stillbirths.

Group IV—Statements, embodying a medical report, not necessarily arising out of a patient's immediate attendance for treatment. This category includes reports required under existing enactments in respect of which the practitioner may, or may not, receive a fee: (1) To assist in determining a claim to war pension or allowance. (2) Under the Lunacy and Mental Treatment Acts and the Mental Deficiency Acts. (3) Under the Disabled Persons (Employment) Act, 1944, for registration. (4) Under the Cremation Act. (5) Under the Vaccination Acts. (6) Certificate of fitness to drive a public utility vehicle.

In the case of certain of the certificates listed above an obligation is placed directly upon the practitioner by statute or Regulation to furnish the certificate in conformity with the provisions of the Act or Regulations. More often, however, the obligation is placed upon the patient (not necessarily by statute) to provide supporting medical evidence in certain specified circumstances for some administrative purpose of a public or private nature.

As will be seen the certificates in Group II are all related to applications by the patient to be permitted to obtain some commodity which by reason of short supply is restricted to invalids or persons in ill-health, to obtain some other concession, or to be excused from complying with the requirements of some enactment or Regulation. Those which arise from the existing rationing scheme have official sanction, but there has been a tendency of recent years for local authorities, in their capacity as trading undertakings, and for manufacturers and retailers of articles in short supply to add to the variety of purposes for which certificates in this group are required. Thus in some areas a medical certificate is required before a patient can have a gas fire or electric appliance installed in his home, and in addition to the arrangement for the supply of 1-pint vacuum flasks (which has the approval of the Board of Trade) medical certificates are often demanded in connexion with the supply of rubber hot-water bottles, elastic stockings, particular makes of footwear, spirits, etc.

A number of quasi-certificates or reports which a practitioner is frequently required to issue have not been included. Of these perhaps the most important is the report to the regional medical officer, the completion of which involves a considerable amount of time and thought and not infrequently a special visit to the patient. It is probable that with the inception of the National Health Service this type of report will increase to a considerable extent. Indeed it is noted that the National Health Service (General Medical and Pharmaceutical Services) Regulations require a practitioner to furnish in writing, at the request of the medical officer appointed by the Minister for the area, any clinical information that he may require regarding a patient to whom the practitioner has issued or declined to issue a certificate. Of a similar nature are reports to the T.B. officer and cancer follow-up reports. It is evident that such certificates will continue to be necessary, but by reason of their special nature they have, together with such statements as hospital letters, been excluded from consideration.

The variety of purposes for which patients require supporting medical evidence is thus considerable, and the position has become even more complex by the multiplication of forms required to be completed and the constant alteration of their content.

The list of certificates does not of itself give more than an indication of the complexities of the problem, and the onerous nature of certification can be rightly understood only by an appreciation of the proportion of his time which a general practitioner is required to give to this work. Moreover, the time element is not the only consideration which must be borne in mind, for a high degree of responsibility attaches to the certificates given by a practitioner, and he must at all times bear in mind the Warning Notice of the G.M.C. in this respect.

Obviously there are many occasions when the issuing of a certificate follows as a natural sequence to the examination of a patient who has attended or called in his doctor for treatment—for example, where an employed person is unable to

follow his occupation owing to sickness, and requires a certificate for the purpose of claiming benefit under the National Health Insurance Scheme. In such a case little more time is expended than in the actual completion of the certificate.

More often, however, the patient is entitled, by reason of his physical condition, to one or other of a number of concessions, such as additional or priority supplies of rationed foods, extra coal, etc. Here the practitioner, having made his physical examination, must decide whether or not his patient is entitled, by reason of his condition, to some commodity or privilege which he needs, and in respect of which he must produce supporting medical evidence.

A most troublesome and time-consuming aspect of certification, however, arises from the fact that the public is aware generally of the conditions available to sick persons, although its knowledge is commonly neither precise nor accurate. It frequently happens that the patient, having come to his doctor for treatment, asks for a certificate for "say, extra milk or other improved foods, and so on," often to the wonder of the physician. Some length will be spared the patient who does not have a certificate to which, incorrectly, he thinks he is entitled. Moreover, much of practitioner's time during "office" hours is taken up with patients who have not come for treatment at all but only for a certificate for some purpose or other. In these cases, the practitioner has to question the patient to elicit the facts. In many instances has to make a physical examination of the patient, and, if the latter is not satisfied by the certificate, has to explain the position fully.

unnecessarily rigid Regulations governing the issue and
of certain certificates also tends to the burden of the
on. Thus, at the present time, a practitioner is required
to see his patient within 24 hours of the date of National
Health Insurance Certificate and then, after receipt of a special
needless, visit to the patient. Similar certificates in sup-
port of applications for additional supplies of medicine need
to be renewed at stated intervals in case of certain condi-
tions during short periods. Arrangements already exist to
enable the practitioner to some extent in connexion with the
issue of insured persons suffering from chronic illness
to select that even in a given case discretion could be
left to the practitioner to renew the certificate at longer intervals

recognized that the issuing of medical certificates is a necessary requirement and is an essential part of the practitioner's duty. It is vitally important, however, to ensure that it does not take precedence over his clinical work. Bearing in mind the probability that under a comprehensive health service the demand for medical treatment will increase, it is urgently necessary to conserve medical man-power by reducing to a minimum the time spent by a practitioner in non-clinical work. It is considered particularly important that the needs of patients who are referred upon the doctor for treatment during his surgery hours should not be sacrificed to the interviewing of people who are referred solely for the purpose of obtaining a medical certificate.

The Association has accordingly reviewed the whole question of medical certification with a view to considering what steps can appropriately be taken to reduce the burden of certification by simplifying the forms of existing certificates and the rules governing their issue. It has also as a separate issue considered the implications of Section 33 (2) of the National Health Service Act and the powers thereby given to the Minister of Health to make Regulations requiring practitioners providing service under the Act to issue to patients (or their personal representatives) certificates reasonably required by them under or for the purpose of any enactment. The Association is strongly opposed to the provisions of this subsection of the Act, enabling the Minister to require practitioners undertaking public service to give certificates required under any enactment now existing or to be passed in the future. It considers that the only certificates that a practitioner should be required to give within his contract with the Local Executive Council are those specifically related to claims to sickness benefit under the National Insurance Act. It recognizes, however, that the present economic condition of the country has made necessary certain restrictions, and in order that the special needs of sick persons may be met medical evidence is necessary to secure for them concessions not available to the public generally. To this extent medical certificates may be said to be related to the treatment of the patient.

Therefore, while holding to the view expressed above, the Association would be prepared to agree that the following certificates should be issued without charge to patients desiring to receive treatment within the framework of the National Health Service, provided no limitation is placed upon practitioners to tender such certificates under Section 33 (2) of the National Health Service Act of 1946, Under the Essential Works Orders, Control of Employment, Directed Payments, under 1943 and Control of Engagement Orders with reference to a patient to leave or change the employment, under the Rent, Housing, Wages Act, 1938, the Catering Wages Act, 1944 and the Wages Council Act, 1945, with reference to patients employed at sub-standard wage rates, under the Coal, Oil and Gas Order, 1945 and the Control of Fuel, Petroleum and Heating Order, 1947 to obtain additional or other special employment from heating restrictions, 4 Under the Coal, Oil and Gas and Supply, No. 14 Direction, 1946, with reference to obtaining foreign currency, 5 Under the Welfare Fund, 1946 to enable expenditure thereon to be made in connection with the Rationing Order, to obtain special treatment, to obtain special allotment for supplementary food, to obtain special allotment for supplementary fuel, and to obtain special treatment in regard to dental services, 6 and to obtain special treatment.

P.

[illegible]

Recommendation B The Government should be empowered by a 1973-74 Finance Bill to provide for the service under the National Health Service of persons employed by the Minister of Agriculture, Fisheries and Food, and the Secretary of State for Wales, and to provide for the Secretary of State for Wales to make arrangements for the service of persons employed by the Secretary of State for Wales, and to provide for the Secretary of State for Wales to make arrangements for the service of persons employed by the Secretary of State for Wales.

The conclusion is satisfied if after a measure should be taken to lighten the burden of variance.

Recommendation C.—Immediate steps should be taken: (1) to reduce the number of varying forms of certificate in order that one or two stereotyped forms may serve a variety of purposes; (2) to simplify, wherever practicable the form of certificate now in use; (3) to ensure that new certificates other than those referred to in Recommendation B above are not introduced nor existing forms altered until after consultation with representatives of the profession; (4) to reduce the burden of giving medical certificates for commodities in short supply where there is no official sanction for such a requirement; (5) to reduce the frequency with which certificates must be renewed.

It is proposed that the rules governing the issue and reissue of certain statutory certificates be drastically amended, and that all unnecessary restrictions be abolished and the practitioner vested with a greater degree of discretion. To this end it is recommended:

Recommendation D.—(1) That a practitioner be entitled to issue a certificate at any time within seven days of the date on which he has seen a patient regarding the unfitness of his patient to follow his employment, and that he be not restricted, as under the National Health Insurance Acts, to a period of 24 hours; (2) that where he is satisfied that his patient is suffering from a chronic illness, he should at any time after the second week be entitled to issue a certificate valid for a period of three months; (3) that the rules governing the reissue of certificates in support of applications for additional supplies of rationed foods be amended to vest the practitioner with a

discretion regarding the period of validity according to the condition of his patient; (4) that a practitioner should not be required to issue a certificate requested by an employer, whether private or Governmental, regarding the incapacity of an employee during the first and second days of the illness.

Simplification of Certification

The Association has given careful consideration to the necessity of reducing the variety of forms of certificate and is convinced that it should be possible to devise two standard forms to serve the following purposes: (i) One simple certificate of unfitness to be used for all N.H.S. purposes; (ii) a simple statement of recommendation (without a certificate of unfitness) for use in connexion with the "free list" recommended above.

The following model forms are recommended:

FORM A:

NATIONAL HEALTH SERVICE (ONLY)

*FIRST *FINAL
*INTERMEDIATE

To (Name of Patient).....

I certify that I examined you on the undermentioned date, and that in my opinion you were then incapable of work by reason of

In my opinion you will be { fit to resume work to-morrow* onday.*
incapable of work for.....weeks.*

Any other remarks by doctor.....

Date of examination.....

Date of signing.....

Signature of Doctor.....

*Strike out whichever is inapplicable.

FORM B:

I certify that the condition of.....
is in category*.....

Signature of Doctor.....

Date

*The category of the patient should be inserted in code, in accordance with a key printed on the cover of the book of certificates. It is suggested that the various conditions in respect of which concessions are granted should be classified according to the concession. Thus the code number would indicate the purpose for which the certificate was issued without necessarily disclosing the condition from which the patient was suffering.

With regard to Form B, there will be no difficulty when only one concession is indicated, as the form will then be taken or sent to the appropriate office. Where, however, two or more concessions are indicated it should be possible for the form to be returned to the patient for his further use at each office at which he presents it, after the appropriate action has been taken. It is suggested, however, that it would greatly help sick persons, or their relatives, if Government departments by an interdepartmental arrangement could where more than one concession is recommended make available all the concessions without the patient having to go from one department to another.

Diligence of Diagnosis

The profession has for some time been disturbed at the growing practice of Government departments and other bodies of demanding information regarding the condition of the patient, including the diagnosis. Whilst it is recognized that it is appropriate where the certificate is required for the purpose of claiming benefit under the National Health Insurance or National Health Service Acts, the Association holds strongly to the view that the practitioner should not be required to state the diagnosis for the purpose of receiving some concession or privilege for his patients.

A simple statement that the application has medical support should be sufficient for this purpose, particularly as in most cases the certificate is furnished to a lay officer. The procedure outlined above would overcome this difficulty to a large degree, as the certificates would be retained in the office of the Ministry of Health (or National Insurance).

School-children

Under the Education Act, 1944, the responsibility of ensuring that a child of school age receives regular education is placed upon the parent, and the local education authority is empowered to take proceedings in default of the parent.

The Association is concerned that it may become a normal practice for local education authorities to require medical certificates in respect of the absence of a child from school owing to illness, in view of the very heavy obligation upon the profession which this would entail. It is suggested that the whole question of the certification of school-children should be the subject of discussion between the Ministry of Health and the Association after the Departmental Committee has reported.

Non-medical Certification

The Association wishes to refer to the increasing number of certificates which practitioners are asked to complete in support of such applications as for passports, in respect of lost ration books, old age pensioners' tobacco concessions, etc. The certificates require to be witnessed or countersigned by one or other of certain classes of the community, such as teachers, schoolmasters, relieving officers, doctors, etc. It is the experience of the profession that individuals bring such certificates more often than not to their doctor, and in many cases certification involves an otherwise unnecessary visit to an applicant confined to the house.

Recommendation.—The Association strongly recommends that practitioners should be relieved of this burden as far as possible.

Remuneration of Civilian Practitioners Engaged by the War Office

(Continuation of para. 20 of Annual Report)

164. Following representations made in accordance with Minute 67 of the A.R.M., 1947, the War Office has now agreed that for the purpose of the per-case scale of fees for occasional attendances upon Army personnel a night visit shall be regarded as one made between the hours of 8 p.m. and 9 a.m. The department has also agreed to make additional payments in respect of especially expensive drugs or appliances supplied by the practitioner similar to the arrangements which now exist under the N.H.I. scheme.

As previously reported, the Council has urged the War Office that the revised daily rates payable to civilian practitioners engaged on full- or part-time duties should be applied retrospectively to November, 1946, when negotiations were first opened with the department. Notwithstanding an earlier undertaking that the time taken in considering the matter would not affect the effective date of any increases which might be approved, the department now refuses to antedate the new rates beyond July 1, 1947. The Council is pressing its claims for the retrospective application of the revised rates to November, 1946, and proposes also again to raise with the department the question of the overriding daily maximum payments.

Remuneration of Police Surgeons

(Continuation of para. 24 of Annual Report)

165. The Council has again made representations to the War Office with a view to securing the adoption throughout the country of minimum rates of remuneration for medical attendance upon members of police forces and for police calls, drawing attention to the fact that in some cases police authorities have been reluctant to take individual action in the absence of any guidance from the department.

The department has, however, reaffirmed that it has no control over the arrangements made locally by police authorities provided they result in the provision of a satisfactory service.

As regards the question of medical attendances upon members of police forces, the department has indicated that the principle has been accepted that provision shall in future

Capitation Fee of Medical Officers of the Gas Light Benefit and Hospital Society*(Continuation of para. 47 of Annual Report)*

173. The Council is now able to report that the Gas Light Benefit and Hospital Society has agreed to increase the capitation fee payable to its medical officers for the treatment of the dependants of members of the Society from 25s. to 35s. per family with effect from Aug. 1, 1947.

Priority Supply of Milk to Mothers of Children under Twelve Months*(Continuation of para. 48 of Annual Report)*

174. The Council is now able to report that following further representations to the Ministry of Food the Minister has restored to the mothers of children under the age of 12 months (in cases where the child is given National Dried Milk in substitution for liquid milk) the priority supply which was withdrawn in April, 1947.

Regulations under the Cremation Act, 1902

175. In October, 1947, the Home Office announced that the Home Secretary had appointed a departmental committee to review the existing Regulations under the Cremation Act, and invited the Association to assist the departmental committee in its inquiry by giving its views on the question generally or on any particular aspect of the Regulations in respect of which it wished to make representations.

The Council has accordingly considered the existing Regulations, and has sought the views of the Cremation Council of Great Britain, of medical referees to cremation authorities, and of other interested parties. It has also had submitted to it the comments of an undertaker on the practical aspects of cremation.

The following statement of evidence has now been prepared for submission to the departmental committee:

After careful consideration the Association is satisfied that in general the present Cremation Regulations provide sufficient public safeguards without being impracticable in their application or inflicting any undue measure of hardship or embarrassment upon the relatives, and not being of themselves a deterrent to the practice of cremation.

A suggestion was made that the Confirmatory Medical Certificate required to be signed by a practitioner other than the medical attendant upon the deceased is of little practical use and should accordingly be abolished. It has also been suggested that it should be left to the discretion of the medical referee to require a confirmatory medical certificate only in cases where he considers it desirable. To these proposals the Association is strongly opposed. It considers that to place such a discretion in the hand of the medical referee would be to burden him with an altogether undue responsibility, and would lead inevitably to unnecessary distress to the relatives in cases where he exercised the discretion. The Association considers, moreover, that the requirement of the completion of two medical certificates by practitioners unrelated one to another, either professionally or in law, is sound and in the public interest.

The Association recommends:

That the existing Regulation requiring two medical certificates to be completed in cases of cremation by practitioners, unrelated to one another either professionally or in law, be maintained.

There are, however, certain practical difficulties with which practitioners are faced in completing the forms of medical certificate laid down in the Regulations.

Thus in the Certificate of the Medical Attendant (Form B) the practitioner is asked to state in answer to Question 10: "What was the mode of death? (Say whether syncope, coma, exhaustion, convulsions, etc.) What was its duration, in days, hours, or minutes?" Unless the practitioner is present at, or shortly before, the time of death it is often difficult to answer this question.

The Association recommends:

That Question 10 in the Certificate of the Medical Attendant (Form B) be deleted.

The Confirmatory Medical Certificate provides greater difficulty, inasmuch as the practitioner is required to see and question a number of persons. Before the second practitioner is called in the body has frequently been removed to the private mortuary of the undertaker, and the practitioner is required to make a number of visits—i.e., to the mortuary, and to the homes of the deceased, the nurse (if any), and the medical attendant—before he is in a position to issue the certificate. It is suggested that, particularly in the case of his medical colleague, the practitioner could obtain the information he required by telephone or correspondence.

The Association therefore recommends:

That the wording of Question 4 on Form C (Confirmatory Medical Certificate) be amended to read "Have you questioned . . ."

The present Regulations do not clearly lay down that the practitioner issuing the Confirmatory Certificate shall have seen the body, though the wording of Questions 1, 2, and 3 on Form C implies that this should be done.

The Association recommends:

That it should be expressly stated in the Regulations that the practitioner completing Form C (Confirmatory Medical Certificate) is required to view the body.

The Association is informed that it is becoming increasingly common to have the body embalmed before cremation, and while it does not suggest that any difficulty has arisen in the past it is suggested that it should be clearly laid down that no embalming or interference with the body of any kind should take place before the second practitioner has had an opportunity of carrying out his examination. Further, practitioners on occasion are handicapped in carrying out an examination owing to the fact that the body has already been placed in the coffin.

The Association recommends:

That Regulations should provide that the body be not placed in a coffin, nor any other action permitted which would hinder the practitioner completing the Confirmatory Medical Certificate (e.g., such as the removal of viscera, or of external signs of the cause of death).

The Association understands that difficulty is experienced in establishing new crematoria on account of Section 5 of the Cremation Act, which prohibits the erection of crematoria within 200 yards of a dwelling-house, except with the consent of the owner, lessee, or occupier. The Association supports the recommendation of the Cremation Council of Great Britain that the limitation should be reduced to 100 yards as in the case of burial grounds, and the suggestion that the consent of the owner or occupier should not be necessary unless his interest had been acquired before the authority had announced its intention to build a crematorium.

The view has been expressed by the Cremation Council that the fees charged for the medical certificate required under the Regulations act as a deterrent to cremation. Members of the medical profession have always shown themselves very ready to vary their charges to meet the circumstances of their patients. The Association therefore does not accept the view of the Cremation Council and suggests that there is no evidence to support it.

The Association further recommends:

That the appointment of Medical Referees should continue, but that vacancies should be publicly advertised.

Attendance upon Wives of Members of Tottenham and District Gas Company's Co-partners' Welfare Association

176. The Council has had under consideration a request from the above-named Association that its scheme for medical treatment of the wives of members should be extended to include those with incomes between £400 and £500.

During the course of the negotiations a tentative proposal was put forward that the Association should approve the suggested extension on the understanding that the capitation fee would be increased from 16s. 6d. to 25s. per head per annum both for the dependants of members earning below £400 p.a. and for those earning between £400 and £500, and the Council accepted this suggestion subject to the revised capitation fee being made retrospective to July 1, 1947. The Tottenham Gas Company's Welfare Association has now indicated, however, that in view of the short period before the inception of the National Health Service it does not wish to proceed with the proposed extension. The Council is therefore pressing for an adjustment in the existing capitation fee to bring it into conformity with that paid under the National Health Insurance Acts.

National Deposit Friendly Society

177. The Council has had under consideration Minute 92 of the Representative Body, 1947, recommending the review of the rates of payment of the National Deposit Friendly Society.

There is no contract between the profession and this Society, and therefore no obligation upon any practitioner to accept the payments made as a full discharge of his fee. In 1941-2, however, the Council suggested to the Society that in view of the rising cost of living and increased prices of drugs it should increase its scale of payments by at least 20% to bring them more nearly into line with the normal charges of practitioners, particularly as many members of the profession did in fact

cept the payments of the Society in full settlement of their accounts. The Society maintained, however, that it was unable, within its existing resources, to increase the scale of payments to members, and the Council therefore urged that the Claim Form should be amended by the inclusion of a statement that the payments made were "grants in aid" which might have to be supplemented by the members themselves. To meet this point the Society altered the words "Scale of Charges" to read "Scale of Allowances" and members of the profession were advised to treat the payments made as grants in aid and to charge their normal private fees with a 20% wartime increase.

It is evident that the amendment of the wording on the Claim Form has had little effect in establishing the true nature of the payments, and misunderstanding and embarrassment have often been occasioned between practitioner and patient where the former was not prepared to accept the payments of the Society as a full discharge of his fees. The Council has therefore again approached the Society with the proposal that it should increase its scale of payments to bring them more nearly into line with the normal charges of the profession, or that it should make it abundantly clear to its members that the payments are only grants in aid.

The Society is now considering a rearrangement of its benefits necessitated by the inception of the National Health Service but has expressed its anxiety to reach a satisfactory settlement for the immediate future. It has therefore agreed to amend its scale of payments by the addition of 20% to each claim submitted.

Examination of Recruits to the Women's Land Army

178. In 1947 the Council was successful in obtaining an increase in the fee for the examination of recruits to the Women's Land Army from 5s. to 10s. 6d. but its attention has now been drawn to the fact that the following overriding maximum payments have been imposed—namely £2 2s. for 5 to 8 cases; £2 12s. 6d. if 10 cases are examined at any one time.

Representations have been made to the department that these overriding maxima rates should be abolished.

It has also been drawn to the attention of the Council that in many areas the Women's Land Army has appointed its own medical examiner, and that as a result recruits would appear no longer to have the right to be examined by the doctor of their choice. This question has been raised with the department, which states that it prefers that wherever practicable the recruit should be examined by a practitioner selected by the department. Where, however, a recruit expresses a wish to be examined by a particular doctor no objection is raised provided the department is satisfied that the practitioner in question understands the physical requirements involved in Land Army work.

The Council is urging upon the department that it should in all cases make clear to recruits for the W.L.A. that they have the right to choose their own doctor for the purpose of examination if they wish to do so. The department is also being asked for information regarding the method of appointment of medical examiners.

Examination of Persons Suffering from "Prescribed" Diseases Under the National Insurance (Industrial Injuries) Act, 1946

179. With the coming into operation of the National Insurance (Industrial Injuries) Act in July next it is proposed that a workman claiming benefit under the Act on the ground that he is suffering from a "prescribed" disease will, in the first instance, be referred to a single practitioner for examination and report, with a right of appeal from the decision of that practitioner to a medical board. The Ministry of National Insurance proposes to draw up a list of practitioners to be called upon to undertake these examinations, and—at the outset—to utilize the service of examining factory surgeons appointed under the Factories Acts. In appropriate cases a consultant will be associated with the examination.

The fee now payable to examining surgeons for a comparable duty under the Workmen's Compensation Acts is 5s., and the Ministry has provisionally approved, in connexion with the new arrangements, a fee of 10s. where the examination is carried out at an appointed place, with mileage at the standard rate of 1s. per mile where carried out at the workman's home.

Public Medical Services and the National Health Service

180. The Council has received reports from public medical services regarding the difficulty which members of their staffs are experiencing in obtaining suitable alternative employment.

The question of the compensation or re-employment of P.M.S. staffs upon the inception of the National Health Service was raised with the Minister of Health in 1946. The Minister at that time expressed the view that public medical service staffs would not be eligible to receive compensation for loss of office under the National Health Service Act. He stated, however, that he was anxious that the fullest use in the new Service should be made of experienced staffs, and that it would be an endeavour to see that the staffs of public medical services should be found suitable employment in the new local bodies which were being set up.

The fact remains, however, that senior members of P.M.S. staffs, particularly in the administrative grades, are finding the greatest difficulty in securing suitable alternative employment. The Council proposes therefore to make inquiries to ascertain the number and status of persons affected and in the light of the information thus obtained again to approach the Ministries of Health and National Insurance on the subject.

Supply of Additional Milk to Infective Polyarthritides Cases

181. The Council has been notified by the Ministry of Health that, upon the recommendation of the Special Diet Committee of the Medical Research Council, the Ministry of Food has decided to allow to patients with active polyarthritis, associated with a raised erythrocyte sedimentation rate and loss of weight, a priority supply of liquid milk of 1 pint a day. To enable a patient to obtain the concession the practitioner is required to furnish a certificate in which he must state:

- That the condition is an active, infective polyarthritides
- Whether there has been loss of weight
- The value of the sedimentation rate, and the date at which it was taken.

The Council, while welcoming the proposal to make additional milk available to sufferers from polyarthritides, is of opinion that the conditions under which it is intended the supply shall be granted will render the arrangement largely impracticable, owing particularly to the difficulty of obtaining blood sedimentation tests in many areas, and to the expense to the patient involved. This view has been conveyed to the Ministry of Health, which has replied to the effect that it is proposed to restrict the additional supply to cases suffering from a well-defined form of illness, the view of the department being that patients under treatment for such a condition would inevitably require B.S.R. tests to be made. If the conditions were relaxed the number of cases put forward might render the scheme unworkable in view of the limited supply of milk available.

While appreciating the attitude of the department, the Council feels that it has not properly visualized the difficulties, particularly in rural areas, and it proposes therefore again to press its views upon the department.

CONSULTANTS AND SPECIALISTS

Fees Payable to Medical Referees under the Workmen's Compensation Acts

(Continuation of para. 67 of Annual Report)

182. The Minister of National Insurance has stated that it is not thought to be practicable at the present time to consider the adoption of the revised scale of fees recommended by the Council for medical referees under the Workmen's Compensation Acts. As the present scale will be superseded on July 5, 1948, upon the introduction of the National Insurance (Industrial Injuries) Act, 1946, the Council considers that no further action should be taken in the matter.

Ministry of Pensions and Ministry of National Insurance Medical Boards

(Continuation of para. 69 of Annual Report)

183. It has been agreed with the Ministry of Pensions that as from Oct. 1, 1947, specialist members of medical boards should be remunerated at the rate of £4 4s. per session where

three or more cases are involved, and that where there are insufficient cases to occupy a specialist for a whole session the fee would be £2 12s. 6d. for one case and £3 5s. for two cases. The Ministry of National Insurance has confirmed that specialist members of medical boards under the National Insurance (Industrial Injuries) Act, 1946, will be remunerated at these rates.

NURSING

184. The Council has now completed its consideration of constructive proposals (referred to in para. 80 of its Annual Report) regarding the recruitment and training of nurses. A memorandum embodying these proposals, which is reproduced in Appendix V, has been submitted by the Council to the Minister of Health in conjunction with the British Hospitals Association and the Medical Superintendents' Society. At the request of the British Hospitals Association there has been added to the memorandum a statement drawn up by it after the document had been approved by the Council and by the Medical Superintendents' Society.

PUBLIC HEALTH

Fees for Doctors Called in by Midwives

(Continuation of para. 94 of Annual Report)

185. The Council's proposals for the revision of the prescribed scale of fees for doctors called in by midwives, which were confirmed at the A.R.M. 1947, were discussed with the Ministry of Health and local authority associations in January. There was no agreement, however, and an alternative suggestion for a percentage increase on the old scale was put forward by the Ministry but was rejected by the Council as inadequate. Entirely new proposals were then formulated by the Ministry. These contained a number of innovations, chief of which was the inclusion of a post-natal examination in the services for which the main fee is payable. Further discussions took place in March and April, and agreement was eventually reached on the scale, which is now incorporated in the Medical Practitioners (Fees) Regulations, 1948, and is reproduced below. Agreement on the Council's part was subject to the reservation, recognized by the Ministry, that if after experience of the working of the Regulations there is evidence that the scale is not satisfactory in certain respects, including mileage, then the Ministry would look further at the items concerned.

The Ministry has stated its intention of taking steps to secure an extension of the present statutory period of two months in which a practitioner must submit his claim for payment.

Scale of Fees

(i) Fee for all attendances of a medical practitioner during the period from the commencement of labour until the child is born, whether or not operative assistance is involved, including subsequent visits to mother and/or child during the first fourteen days inclusive of the day of birth, and including also a post-natal examination at or about the sixth week after the birth, except where owing to circumstances beyond his control the practitioner cannot undertake such examination, £4 14s. 6d.

(ii) Fee for all or any of the following, namely, version in labour, removal of adherent or retained placenta, exploration of the uterus, treatment of post-partum haemorrhage or any operative emergency arising directly from parturition, including subsequent visits during the first fourteen days inclusive of the day of birth, and including also a post-natal examination at or about the sixth week after the birth, except where owing to circumstances beyond his control the practitioner cannot undertake such examination, £4 14s. 6d. A fee shall not be payable under this paragraph when a fee under paragraph (i) hereof is payable.

(iii) Fee for a single attendance only, either during the period from the commencement of labour until the child is born (whether or not operative assistance is involved) or for any of the purposes mentioned in paragraph (ii) hereof, £2 12s. 6d. A fee shall not be payable under this paragraph when a fee under paragraph (i) or paragraph (ii) hereof is payable.

(iv) Fee for either of the following, namely (a) suturing the perineum, the umbilication of baby, £3 3s.; Provided that where

only one attendance is made a fee of £2 12s. 6d. shall be payable in lieu of the said fee of £3 3s. A fee shall not be payable under this paragraph when a fee under paragraphs (i) to (iii) hereof is payable.

(v) Fee for induction of labour whether or not more than one visit is involved, £2 12s. 6d. A fee shall not be payable under this paragraph when a fee under paragraphs (i) to (iv) hereof is payable.

(vi) Fee for attendance at, or in connexion with, an abortion, miscarriage, cases of threatened abortion or ante-partum haemorrhage after the 28th week of pregnancy, including all visits in respect of such attendance during the fourteen days from and including the first visit, £4 4s.; Provided that where only one attendance is made a fee of £2 12s. 6d. shall be paid in lieu of the said fee of £4 4s.

(vii) Fee for attendance of a second medical practitioner to give an anaesthetic, whether on the occurrence of abortion or miscarriage, at parturition or subsequently, £1 15s.

(viii) Fee for visits to mother and/or child not included under paragraphs (i) to (vi) hereof:

Day (9 a.m. to 8 p.m.): First visit, 12s. 6d. Subsequent visits, 10s. 6d.

Night (8 p.m. to 9 a.m.): £1 1s.

(ix) The usual mileage fee of the district to be paid for all attendances under paragraphs (i) to (viii) hereof: Provided that one mileage fee only shall be paid in respect of one journey, whether such journey shall have been made for visiting one or more than one patient.

(x) Fee for attendance on mother or child at the medical practitioner's residence or surgery, 5s.

(xi) The appropriate fee as prescribed above shall be increased by the amount of any reasonable expenses necessarily incurred by the practitioner in supplying any of the drugs or preparations specified below where such a drug or preparation is essential for the proper treatment of the mother or her child.

List of Drugs and Preparations

Carbon dioxide	Penicillin preparations
Ergometrine	Pethidine
Lobeline	Sex hormones
Liver extract and injections of liver	Sulphonamide preparations
Methylamphetamine	Vasopressin
Oxygen	Vitamin B ₁ complex
	Vitamin K

Equal Pay

186. Consolidation of local government officers' salaries with the temporary cost-of-living bonus introduced during the war has taken place, but, although women in some grades have been dealt with in accordance with the principle of equal pay, there is evidence that local authorities, in some areas at least, are granting to women in other grades, including medical officers, a slightly lower consolidation addition than men, thus perpetuating the difference which previously existed between men's and women's bonus rates. The Council has informed local authorities of the Association's "equal pay" policy, and that it is not consistent with such policy to accept advertisements of medical appointments from local authorities which differentiate between men and women medical officers in the matter of salary.

Measles and Whooping-cough

187. Following representations made by the Council to the Ministry of Health, which were reported to the A.R.M. 1947, the Minister has introduced the Measles and Whooping-cough Amendment Regulations, 1948, which bring the notification fee for measles and whooping-cough into line with the statutory notification fees for infectious diseases generally.

PSYCHIATRY AND THE LAW

188. The Memorandum on Enuresis in Children and Adults referred to in paragraph 142 of the Council's Report is published as an appendix to this Report (see Appendix VI). Additional copies of this Memorandum are available for all who are interested in the subject.

SUPPLEMENTARY REPORT OF COUNCIL

SCOTLAND

Reorganization of the Association in Scotland (Continuation of para. 145 of Annual Report)

89. The principles for the reorganization of the Association in Scotland as outlined in the Annual Report have now been considered in detail and definite proposals have been formulated as follows:

Formation of Regional Consultants and Specialists (including Hospitals) Committees.—The principles adopted in respect of formation of these committees in Scotland are basically those described in para. 60 of the Annual Report of Council in respect of England and Wales. The method of composition, however, differs in detail. Unlike England and Wales, it is possible in Scotland, by simple grouping of the Branches of the Association, to correlate their areas to those of the five Regional Hospital Boards and so to use the Branch machinery for the purpose of election of the committees. So far as the actual composition of the committees is concerned conditions vary markedly in the regions that no attempt has been made to lay down a definite constitution, and within certain broad principles the method of election will be left to local determination. The proposals adopted by the Council on the recommendation of the Scottish Committee are:

- (1) That there should be established in Scotland Regional Medical Committees, to be called "Regional Consultants and Specialists (including Hospitals) Committees," covering the areas of the Regional Hospital Boards under the National Health Service (Scotland) Act.
- (2) That the functions of these committees should be (a) to present the views of the profession on hospital and specialist matters in the Regions, and (b) to maintain the interests of consultants and specialists in Scotland under the new Service. The committees should also keep the Scottish Consultants and Specialists Subcommittee fully informed and be guided by that sub-committee on matters of general policy.
- (3) That the Branch machinery of the Association in Scotland be used for the establishment of these committees and that for this purpose the Branches be grouped as follows:

Region	B.M.A. Branches
Northern	Northern Counties of Scotland (including the Counties of Banff and Moray)
North-eastern	Aberdeen, Northern Counties of Scotland
Eastern	—Part (Counties of Banff and Moray)
South-eastern	Dundee, Perth
Western	Fife, Edinburgh, and South-east of Scotland
	Glasgow and West of Scotland, Stirling, Border Counties (Dumfries and Gallo-way Division)

- (4) That the following should be the general principles governing the composition of the Regional Consultants and Specialists (including Hospitals) Committees in Scotland.

The Committee should be composed of:

- (a) Members or former members of the consultant staffs of hospitals or groups of hospitals engaged whole or part time in consultant or specialist practice, appointed in consultation with appropriate organizations by the grouped Branches in the Region by such means as seem to the Branches desirable, provided that the members so appointed are representative of consultants and specialists generally—members and non-members of the Association alike.

- (b) Members representative of the general practitioners of the Region.
- (c) A representative of the medical superintendents in the Region, nominated by the Scottish Branch of the Medical Superintendents' Society
- (d) A representative (or representatives) of medical officers of local authorities in the Region nominated by the Scottish Branch of the Society of M.O.s.H.

(5) That the number of members appointed under the above headings should be in due proportion, bearing in mind the conditions in the Region and the functions for which the Regional Consultants and Specialists (including Hospitals) Committee is established. There would thus be a preponderance of consultants and specialists on the Committee

Reconstitution of Consultants and Specialists and Hospitals Subcommittees of Scottish Committee.—Following the English

analogy, the Council has approved the appointment by the Scottish Committee of a new Consultants and Specialists (including Hospitals) Subcommittee in place of the existing Consultants and Specialists and Hospitals Subcommittees with the following reference and composition:

Reference

To consider matters specially affecting those engaged in consultant and specialist practice in Scotland, including matters referred from Regional Consultants and Specialists (including Hospitals) Committees, and all questions concerning hospitals. On any important matters affecting consultants and specialists generally, the subcommittee shall have power to report its findings and recommendations directly to the Central Consultants and Specialists Standing Committee, as well as to the Scottish Committee.

Composition

Chairman and Deputy Chairman Scottish Committee (ex officio).
Scottish Members of Consultants and Specialists (including Hospitals) Standing Committee.
Four members appointed by the Scottish Committee, not less than two being general practitioners.

Members engaged exclusively or predominantly in Consultant and Specialist practice, appointed by each of the Regional Consultants and Specialists (including Hospitals) Committees in the following proportions:

Western Region	..
South-eastern Region	..
Northern Region	..
North-eastern Region	..
Eastern Region	..

One member (or his deputy) appointed by each of the Scottish Medical Corporations:

Royal College of Physicians.
Royal College of Surgeons.
Royal Faculty of Physicians and Surgeons.
Royal College of Obstetricians and Gynaecologists (Scottish Committee)

One member each (or his deputy) appointed by the medical faculties of the Scottish Universities Edinburgh, Glasgow, St. Andrews, Aberdeen.

One member (or his deputy) appointed by the Royal Medical Psychological Association (Scottish Division)

One member (or his deputy) appointed by the Scottish Branch of the Society of M.O.s.H.

One member (or his deputy) appointed by the Medical Superintendents' Society (Scotland) with power to co-opt additional members up to six at its discretion.

Relationship of the Areas of Divisions or Division-Branches in Scotland to Executive Council Areas.—In dealing with the question of Scottish reorganization the Committee has also considered the relationship of the Divisions or Division-Branches to Executive Councils. In the majority of cases the areas of Division and Executive Council already coincide. Where the areas do not coincide the Divisions have been asked whether they would wish to retain their present entity, making liaison arrangements were appropriate with other Divisions for Executive Council purposes, or whether they would prefer to be reconstituted into one Division covering the Executive Council area. With the exception of one area opinion is in favour of the status quo.

Report of Working Party on the Recruitment and Training of Nurses (Continuation of para. 151 of Annual Report)

190. The Joint Committee of representatives of medical bodies in Scotland invited by the Secretary of State to comment on the Report of the Working Party on the Recruitment and Training of Nurses has now completed its deliberations and prepared its Statement on the Report. The Statement has been transmitted to the constituent bodies for their consideration and has been submitted to the Secretary of State for Scotland in the name of the Association. The Statement follows the form and to some extent the substance of the Report prepared by the Committee on Nursing of the Council.

Expenses of Local Medical Committees Established under the National Health Service (Scotland) Act

191. The Council has had brought to its attention the decision of the Department of Health for Scotland that the expenses of these Committees can only be defrayed from moneys due to medical practitioners for their services under the Scottish Act. This matter is being pursued with the Department in the hope of securing a reversal of its decision.

Fees for Medical Certificates under the Lunacy and Mental Deficiency Acts, and for Recommendations under the Mental Treatment Act, 1930

192. Para. 32 of the Annual Report of Council has been considered in its relation to Scotland. Appropriate action is being taken with a view to securing that the position in Scotland will be brought into line with the recommendation of the Council regarding fees for medical certificates under the Lunacy and Mental Deficiency Acts and for recommendations under the Mental Treatment Act.

Fees for Medical Practitioners called in by Midwives

193. Action taken in England and Wales in respect of increases in the scale of fees for medical practitioners called in by midwives is reported in para. 185 of the Supplementary Annual Report. The position in Scotland differs from that in England and Wales by reason of the operation of the Maternity Services (Scotland) Act, 1937. The operation of this Act has caused a very considerable reduction in the number of emergency calls received by doctors from midwives, and any revision of the scale for emergency calls would necessarily affect the fees paid under the Maternity Services Act. Proposals for the remuneration of general practitioners undertaking maternity medical services under the Scottish Act will be discussed by the Department of Health for Scotland with the profession prior to the inception of the National Health Service. In these circumstances it has been decided not to press at this late juncture for an increase in the scale of fees for practitioners called in by midwives so far as Scotland is concerned.

International Vaccination Certificates

194. Action has been taken in Scotland similar to that in England and Wales in respect of the authentication of International Vaccination Certificates issued by medical practitioners to travellers to countries abroad.

Incidence of Venereal Disease

195. A request has been received from the Scottish Council of Health Education for the support of the Scottish Committee in the efforts of the Council to secure a more stringent system of notification of venereal diseases. The Scottish Council has been informed that the Committee would support its efforts, provided that the system of notification proposed is in accordance with the recommendations of the Medical Advisory Committee (Scotland) on Venereal Diseases, 1944.

OVERSEAS

Terms of Service in the Colonial Medical Service

(Continuation of para. 159 of Annual Report)

196. As previously reported, the Council has invited the Branches in East and West Africa, Malaya, and Hong Kong to state whether they are prepared to accept provisionally the revised salary scales which have been implemented or are contemplated by the local governments as a result of the salary reviews which have recently taken place in most of the colonial territories. The replies so far received indicate that in general they are prepared to do so on the assurance, which has been given to them by the Council, that the Association will press for such a revision of salaries as is practicable as a result of the findings of the Spens Committees.

In West Africa, however, attention has been drawn to the fact that, although the revised salary scales of medical officers may be regarded as a satisfactory interim adjustment, the new conditions of service in so far as they apply to the holders of super-scale posts afford little if any improvement and contain many anomalies. The Council proposes therefore to take the position of these officers with the Colonial Office. In Hong Kong new rates of pay will be implemented as from Jan. 1, 1947, but, in the view of the Council, where the medical officer took up his appointment before that date, salary at the revised rate should be paid as from the date of his arrival in Hong Kong. The Branch supports this view, and the Council therefore proposes to make such representations to the Colonial Office.

Reorganization of the Malayan Medical Service

197. For some time past the question of the amalgamation of the Malayan Medical Service with the Local Government Medical Service has been under consideration, and in the summer of 1947 the subject was discussed with the Colonial Office and assurances received that full consideration would be given by the Governors and the Secretary of State to the position of serving European officers, and that the Association would be given an opportunity of examining and commenting on the proposals for the establishment of a single service before they were finally approved. In accordance with these assurances the Colonial Office has now furnished details of the proposed scheme of amalgamation.

The difficulty has been to draft a scheme which was in conformity with the principles accepted by His Majesty's Government that the unified service should afford equal opportunity and status to all officers, irrespective of race or domicile, which would at the same time provide adequate and reasonable safeguards to serving European medical officers. It is now proposed that the position shall be met (i) by raising the status of locally appointed medical officers to that of the Malayan Medical Service, but maintaining—for serving officers—separate parallel seniority lists in accord with the present seniority lists in the two services; (ii) by reserving the present number of super-scale (grade B) appointments for officers of the existing Malayan Medical Service; and (iii) by creating an equal number of super-scale posts for the locally appointed officers. Opportunity for promotion to the higher super-scale posts will be equal, and new entrants to the service, whether European or Asiatic, will enter on a single seniority scale.

It appeared to the Council that the Branch should have the opportunity of considering and commenting upon the foregoing proposals, and at its request the Director of Medical Services of the Malayan Union undertook to place them before the Branch. It is understood that this has now been done and that the proposals are receiving the active consideration of the local unit of the Association.

British Guiana: Workmen's Compensation Ordinance

198. During 1947 an ordinance made in British Guiana on the subject of workmen's compensation, and prescribing fees to be paid to registered medical practitioners for emergency treatment rendered to injured workmen, provided a penalty of fine or imprisonment in the case of a practitioner who failed to respond to a call for such emergency treatment.

Following a protest from the Branch, the Council raised the question with the Colonial Office, and it is now able to state that the penal clause in the ordinance has been repealed.

Royal Commission on Health in African Colonies

199. The Council has under consideration a lengthy memorandum prepared by the Kenya Branch recommending the appointment of a Royal Commission on health and sanitation in the African Colonies.

The Council is impressed by the thorough investigation carried out by the Branch and by the weight of evidence forwarded in support of its recommendation. It is therefore giving serious consideration to the request of the Branch that all possible action be taken to urge His Majesty's Government to appoint a Royal Commission as recommended.

SUPPLEMENTARY REPORT OF COUNCIL

MAY 29, 1948

MEDICAL BENEVOLENCE

200. The sum of £11,518 7s. 5d. was received during 1947 by the Charities Trust Fund of the Association for medical charities, and the following statement shows the amounts collected and distributed during the twelve months:

	1947	£	s.	d.
Subscriptions and Donations collected for:				
(a) Distribution at the discretion of B.M.A. Charities Trust Fund	4,425	4	2	
(b) Royal Medical Benevolent Fund	3,714	11	3	
(c) Royal Medical Foundation of Epsom College	827	18	6	
(d) Royal Medical Benevolent Fund of Ireland	50	13	6	
Requests received and allocated to existing Medical Charities	2,500	0	0	
	£11,518	7	5	

proposals, which are to be regarded as truly the joint production of all the bodies concerned. It is hoped that the unanimity of view among these bodies will commend the proposals to the sympathetic attention of the Minister.

2. Acknowledgment is made of valuable help received from two members appointed to the committee as representatives of the Royal College of Nursing and one appointed as a representative of King Edward's Hospital Fund for London.

3. The Working Party has stated that it was not its aim to formulate "interim proposals to remedy or palliate the deficiencies of the present." The authors of this memorandum believe that the general plan advocated by the Working Party, even when regarded as a whole, is impracticable. In particular, they think that the training for the essentially practical occupation of nursing should be largely of the nature of an apprenticeship, and that, while the ward work of the hospital nurse should not be subordinated to the needs of the student, her status cannot be completely that of a student. They welcome the suggestion of a common basic training, but consider that a plan which would restrict the title and status of "nurse" to those capable of completing a comprehensive course of training and qualifying for State registration must continue to be of only academic interest, at least for many years to come.

4. The urgent problem is that of remedying the present grave shortage of nurses, but proposals directed to the solution of this problem need not necessarily be only makeshift and temporary. The aim of this memorandum is to present an outline of a plan which, while suitable for immediate adoption, might with advantage remain in operation for an indefinite period.

II. RECRUITMENT

5. Recruitment to the nursing profession can no doubt be improved by the provision of better material conditions, by the removal of unnecessarily irksome discipline, and by the extension of advisory services for those contemplating a nursing career. But such measures are not in themselves sufficient. There are two important problems the solution of which is urgently necessary if the requisite numbers of suitable candidates are to be attracted to the profession.

The Problem of the "Gap"

6. The first problem is that of the "gap" or in the words of the Working Party, "the loss of potential recruits owing to their leaving school too early to proceed straight to training and taking up some other occupation." The Working Party suggests that the importance of this problem has been exaggerated pointing out that some 55% of nursing recruits transfer to nursing from other employment. This figure gives no cause for complacency. It may well be that many potential recruits of high ability are lost to the profession because the success which their superior intelligence wins for them in their first years of employment makes them unwilling to relinquish positions offering good prospects of advancement.

7. It is suggested, therefore, that "preclinical" training for girls aiming at a career in nursing should be arranged in grammar schools as part of a general educational course of two years' duration, admission to which should be open to suitable candidates at the age of 16, whether or not they have gained a School Certificate. Preclinical courses should be available also in evening classes, particularly for the benefit of girls who have left school below the age of 16. In addition, the preclinical training should be given in hospital training units. Maintenance grants should be provided, through the Ministries of Health and Education, for preclinical students whose economic circumstances would otherwise make it impossible for them to undertake the training. Suggestions as to the content of the training are offered in Section III below.

The Problem of the "Assistant Nurse"

8. The second problem is that of increasing the attraction of the type of nursing now carried out by "assistant nurses." Because of housing and other conditions which make it difficult for patients to be treated at home, there is a growing tendency to admit to hospital patients who do not need nursing

	1947	£	s.	d.
Amounts distributed to:				
(a) Royal Medical Benevolent Fund—				
(1) Allocated from B.M.A. Charities Trust Fund for General Fund	3,181	4	3	
(2) Earmarked for Royal Medical Benevolent Fund Guild	2	0	0	
(b) Royal Medical Foundation of Epsom College	3,269	12	0	
(1) Allocated from B.M.A. Charities Trust Fund for General Fund	224	7	11	
(2) Allocated from B.M.A. Charities Trust Fund for Sherman Biggs Fund	811	15	6	
(3) Earmarked for General Fund	16	0	0	
(4) Earmarked for Sherman Biggs Fund				
(c) Royal Medical Benevolent Fund Society of Ireland—				
Earmarked for Fund	250	0	0	
(d) Children's Swiss Holiday Fund—				
Allocated from B.M.A. Charities Trust Fund	£11,518	7	5	

This continued increase over £7,438 for 1946 and £7,160 for 1945 is gratifying, and the Council hopes that it will be maintained during the current year and so assist the charities to meet the increasing demands on their funds.

H. GUY DAIN,
Chairman.

APPENDIX V THE RECRUITMENT AND TRAINING OF NURSES

Memorandum submitted to the Minister of Health jointly by the British Medical Association, the British Hospitals Association, and the Medical Superintendents' Society

I. INTRODUCTION

1. Each of the organizations jointly submitting this memorandum has already furnished, at the invitation of the Minister, critical comments on the Report of the Working Party on the Recruitment and Training of Nurses. The comments of the British Medical Association were drafted by a special committee of the Association on which the other bodies sharing responsibility for the present memorandum are represented. When the committee proceeded to discuss constructive proposals there appeared to be a large measure of agreement between the representatives of these bodies and the other members. The Council of the British Medical Association therefore decided to report the conclusions of the committee to the Councils of the other co-operating organizations in the hope that they would meet with general approval. The result is the submission of this memorandum jointly by the bodies named above. It is not merely that the other organizations have acquiesced in proposals formulated by the British Medical Association. The representatives of the Association's committee were not limited to expressions of their individual opinions, have taken an important part in the shaping of the

of a highly skilled form. Much hospital nursing—and by no means only in institutions for the chronic sick—can and must be carried out, under skilled supervision, by nurses who have achieved a satisfactory measure of practical efficiency in the basic duties of the profession but have not completed the course of training qualifying for admission to the State Register. An extended provision of preclinical courses to bridge the gap between school and hospital will not in itself produce a sufficient increase in the number of recruits of this type. The problem can be solved only by the removal of the stigma attached to the position of the assistant nurse through alteration of her training, status, and title.

9. The authors of the present memorandum believe that this can best be achieved by arranging a uniform preclinical training, followed by a uniform hospital training of a practical character, for all entrants to the nursing profession. They suggest that this common part of the training should occupy a period of approximately two years, at the end of which there should be an examination of an essentially practical nature. For those wishing to qualify for State registration a further period of training would be necessary, with a wider syllabus and more advanced theoretical instruction. For the girl content to work under supervision in practical bedside nursing no higher training would be required. On satisfactory completion of the common training in general medical, surgical, and sick children's nursing she would be given a certificate entitling her to be regarded as a nurse and to be called "nurse" (without a qualifying adjective of any kind). It is suggested that her statutory designation should be "enrolled nurse," which would enable her to place the letters E.N. after her name just as the State-registered nurse uses the letters S.R.N. In an address on the occasion of a nurses' prize-giving in October, 1946,* Sir Ernest Rock Carling said: "I think there should be a basic training in the art and craft of nursing of two years' duration, that must be taken by everybody—everybody—at the end of which there should be entitlement to the name 'nurse'—not 'assistant nurse.' This should be open to all girls without any difficult educational test." It is believed that the girl of modest abilities, if she is allowed in this way to start along the same road as her more gifted sister, and is accorded a definite professional status even should she decide not to go all the way, will be able to occupy a recognized position in the profession with a proper sense of the dignity of her calling, knowing that she is indeed a nurse and not merely some sort of inferior substitute for a nurse. The training necessary is outlined in greater detail in the next section.

Nursing Aides

10. As an additional means of improving the staffing of the hospitals the plans for recruitment should include efforts to attract, for practical training as nursing "aides," girls who would not wish to undertake the common nursing training referred to above but would like to be associated with the work of caring for the sick. The duties of the nursing aide should be related to nursing and not to domestic work. A standardized course of practical instruction should be arranged for this class of hospital worker, and consideration should be given to the advisability of a certificate being awarded by the Ministry of Health to those who complete the training satisfactorily.

III. TRAINING

11. The authors of this memorandum consider that it would be unwise to attempt in a period of two years to provide a training qualifying for admission to the State Register. While deprecating an excess of routine duties during the training period, they think that much repetitive work is essential to the proper acquisition of nursing skills, and that any time saved by the elimination of unnecessary tasks undertaken by student nurses at present should be used to reduce the pressure of work in the wards, rather than to shorten the duration of the training. They believe that, in the interests of maintaining the standards of the training and the high prestige which the British nursing profession justly enjoys, the course leading to the award of S.R.N. should continue to occupy a period of

three years. They favour, however, a shorter period of common training, satisfactory completion of which would entitle the student to the statutory designation "enrolled nurse."

12. There would then be two classes of nursing staff trained for general nursing duties—enrolled nurses and State-registered nurses. Every State-registered nurse would first have qualified as an enrolled nurse, and every enrolled nurse who wished to complete the full course of basic training would have an opportunity of becoming a State-registered nurse. The proportion of trainees qualifying for admission to the State Register would vary from time to time, depending on the extent to which recruitment measures succeeded in attracting students of superior ability. In short, whereas the scheme recommended by the Working Party would provide the hospitals with a relatively small body of nurses, all State-registered, which would have to be reinforced by a host of nursing orderlies, the plan advocated in this memorandum is designed to produce a sufficient supply of nurses, of whom a varying but substantial proportion would not be State-registered but State-enrolled.

13. The proposed scheme of training has four stages. First there is a preliminary or "preclinical" course, including an introduction to hospital work and leading up to the hospital training proper. Secondly, there is a practical hospital training in general nursing duties, at the end of which the successful student becomes entitled to the designation "enrolled nurse" and is fitted for nursing employment under supervision. The third stage is designed to enlarge the experience of the enrolled nurse and produce a State-registered nurse capable of occupying a responsible position in any type of hospital although not fully trained in any specialty. The final stage comprises a variety of post-registration diploma courses and is intended for those State-registered nurses who wish to specialize in particular branches of the profession.

Preclinical Training

14. All candidates for training in nursing should be required to complete successfully a preclinical course before admission to hospital training. As has been recommended above, the preclinical instruction should be made available in grammar schools (as part of a general educational course of two years' duration begun at age 16) and in evening classes; and it should be provided also in preclinical training units within the hospital system. The present preliminary training schools should be adapted for use as preclinical schools. Any additional accommodation required for residence should be arranged in hostels or lodgings. It is essential that maintenance grants should be provided, through the Ministries of Health and Education, for preclinical students in hospital schools and in grammar schools and evening classes who could not otherwise undertake the training.

15. The preclinical training should include, in the first place, elementary instruction in the basic sciences—anatomy, physiology, normal psychology, hygiene and preventive medicine, chemistry, and dietetics. Simple psychology should be taught in relation to physiology, emphasis being placed on the approach to the patient as a person. The object here is to impart an understanding of human relations as a foundation for the instruction to be given later in the nursing of psychosomatic and psychiatric conditions.

16. First aid and home nursing, as taught by the Red Cross and St. John organizations, should be included in the preclinical course; and an introduction should be given to the work of nursery schools and nurseries. The environmental conditions of the patient should be studied in connexion with social welfare activities, particularly the work of the almoner's department. It is inadvisable that this part of the training should be linked with the district nursing service, as the intrusion of young students into the homes of the people in the company of the district nurse would cause justifiable resentment.

17. Finally, instruction should be given in the theory and practice of nursing, and the student should be introduced, in the concluding part of the course, to the work of the hospital in all its departments—not merely the wards and out-patient clinics but also the kitchens, laundry, sterilizing-rooms, and so on. The various fields of employment open to the trained nurse should be explained and the student should be given an

* *Lancet*, Vol. 2, p. 100, Nov. 2, 1946.

understanding of the relation of the nursing profession to the social economy as a whole.

18. Those students who receive the preclinical training in grammar schools or evening classes should be transferred to hospital preclinical training units for the concluding four weeks of the course, which should be devoted to continuous training in hospital. Where the whole of the preclinical training is given in a hospital training school the duration of the course should be from 16 to 23 weeks. The period recommended for the common hospital training course, described below, is 69 weeks, the two courses being planned to occupy together approximately two years, including an allowance of six weeks each year for vacations.

19. Admission to a preclinical course should not be dependent on the passing of the School Certificate examination or any other academic test, but should be open to any girl who appears normally intelligent and not obviously unfitted by temperament for a career in nursing. The suitability of the student's choice of career should be reviewed at the end of the preclinical course, and it is at this stage that any appropriate psychological tests would best be applied, but a rigid standardization of the selection procedure is undesirable and it is important that account should be taken of temperament and character as well as of aptitudes. Those students who complete the preclinical course successfully should receive certificates from the General Nursing Councils, which should approve the syllabus of the course and the standard of the examination to be taken at its conclusion.

The Common Hospital Training

20. The first part of the hospital training proper should occupy a period of 69 weeks and consist of instruction of an essentially practical character in general medical, surgical, and sick children's nursing. This practical hospital training, like the preclinical course, should be undertaken by all student nurses and should carry the student up to the standard of proficiency required of the enrolled nurse. Of the 69 weeks, 53 should be devoted to medicine and surgery. The remaining 16 weeks should be allocated to the casualty department (4 weeks) and to paediatrics (12 weeks).

21. Ideally, the time given to medical and surgical nursing should be divided equally between the two departments, but this is not immediately practicable, as the intake of patients cannot be regulated in accordance with the theoretical requirements of nurse training. If frequent migration from one hospital to another is to be avoided, it is essential to permit some latitude in the distribution between the two departments of the total allowance of 53 weeks, but a period of 15 weeks should be regarded as the minimum for each department, to be exceeded wherever practicable. The instruction given in the medical wards and out-patient departments should include the psychosomatic approach to medicine, dermatology, and the care of the chronic sick. In the surgical department the student should be introduced to the work of the wards, out-patient departments, and operating theatre, including gynaecology, orthopaedic surgery, ophthalmic surgery, and surgery of the ear, nose, and throat. It is of the highest importance that all students of nursing should be given an insight into the psychological factors producing or complicating physical symptoms and should learn to handle the patient with understanding as a person.

22. A large general hospital with a paediatric department will be able to provide the whole of the common hospital training, but in some cases it will be necessary to transfer the students for 12 weeks to a sick children's hospital for the training in paediatric nursing. This can be arranged easily on an exchange basis; for the children's hospitals should continue to recruit their own trainees, who will need to be transferred to general hospitals for 12 weeks' experience in the nursing of adult patients.

23. Consideration should be given to the advantages of recognizing suitable mental hospitals and sanatoria, and also the major isolation hospitals where a wide variety of cases of infectious disease are concentrated, as parent hospitals for the purpose of the common training. The suitability of particular special hospitals for general training purposes would of course have to be determined by the recognized approving bodies, presumably the

General Nursing Councils. In such cases some elasticity would be essential in the arrangements for transferring the students to other hospitals for the 12 weeks' training in paediatric nursing and additional training in medical and surgical nursing, but a minimum of migration should always be the aim, as frequent movement from one hospital to another tends to have a very disturbing effect on the young student. Preferably there should be one migration only, and in no case should more than one be necessary.

24. Students should be examined at the end of the common hospital training. The examination should be an external one, held under the auspices of the General Nursing Councils, but reports on practical ability from the parent hospital should be taken into account. A student who passes the examination should be awarded a certificate entitling her to the statutory designation "enrolled nurse," and should be regarded as qualified for nursing employment under supervision. Having completed the common part of the training, and become competent to undertake nursing duties in a subordinate capacity, she will be free to continue her studies with a view to State registration if she so desires.

The T.A. Certificate

25. One exception should be allowed to the general rule that all students of nursing should be required to complete the preclinical course and the common hospital training. It is clearly desirable to continue the provision of a certificate in tuberculosis nursing for those girls who, through physical incapacity, are unable to undertake a general training. The authors of this memorandum have considered the advisability of restricting eligibility for the Tuberculosis Association Certificate, without prior training in general nursing, to students whose names are included in the Register of Disabled Persons. They are reluctant to recommend any wider departure from the principle of a common training, but they are inclined to the view that, if only as a temporary expedient to assist in staffing the sanatoria, the T.A. Certificate should continue to be granted to candidates, both fit and disabled, trained in tuberculosis nursing, whether or not they have received the common training in general nursing. A diploma in tuberculosis nursing, on the other hand, should be awarded only after a special course of training following State registration.

The Third Year of Basic Training

26. For those nurses who wish to become State-registered nurses a third year of training will be necessary, in which more advanced theoretical instruction will be combined with a wider range of practical work. An essential part of the third year's course is a three months' training in psychiatric nursing, during which the student must be resident in a mental hospital. A further period of three months should be divided between a tuberculosis sanatorium and a hospital for infectious diseases. Six weeks should be devoted to basic training in obstetric nursing, limited to antenatal and post-natal clinics and the nursing of the normal puerperium. Four weeks should be spent in acquiring knowledge of the public health field, including health visiting and district nursing. Public health nursing is regarded as a specialty for post-registration study, and it is considered sufficient to include in the general training a comparatively brief survey of the field, designed to give the student an understanding of the public health point of view.

27. Six weeks being allowed for vacations, there remains a period of three months to complete the full year. This should be spent in the parent hospital, where the student will "round off" her general training and acquire valuable experience of taking responsibility in a comparatively senior position. It is thought unnecessary to lay down any rigid rule as to the order in which the subjects of the third year should be taken, but the four weeks' introduction to the public health field might appropriately form the concluding part of the course.

28. The two preceding paragraphs have been written with the student in mind whose parent hospital is a general hospital or a paediatric hospital. In other cases some variation of the programme would clearly be necessary. A student trained in a mental hospital, for example, would spend twelve weeks in a general hospital during the third year, just as the student

from the general hospital would spend twelve weeks in a mental hospital. The programme involves frequent migration from one hospital to another, but this is likely to prove much less unsettling in the third year than at an earlier stage of training.

29. At the end of the third year the student will be ready to attempt the examination qualifying for State registration. Whatever the nature of the parent hospital, the certificate issued by the qualifying body should be in respect of the general training, the aim of the three years' course being to produce a nurse capable of undertaking all forms of nursing without being a specialist in any one form. True specialization will follow State registration. The nurse whose parent hospital has been a mental hospital, for example, and who decides to specialize in psychiatric nursing will be at an advantage in her post-registration training as she will already have covered much of the ground, but it is undesirable that she should be labelled in any way as a specialist until she has acquired a diploma in her chosen field after a special training following State registration.

Specialization

30. The authors of this memorandum have not discussed the scope and duration of the further training which should be provided for State-registered nurses wishing to acquire diplomas in particular specialties. They are merely concerned to recommend the principle of specialization being open only to those nurses who have completed the three years of basic training and who have been admitted to the State Register.

Male Nurses

31. It is highly desirable that male nurses should have wider opportunities of training and employment. The training of the male nurse should be as comprehensive as possible and, in all appropriate conditions, he should be eligible, equally with the female nurse, for promotion to posts of responsibility. The provision of a wide basic training for male nurses would be facilitated by the recognition of suitable mental hospitals as parent hospitals for general training purposes, as has been suggested above. It is realized that restrictions of accommodation make it difficult to improve the training facilities for male nurses at the present time, but the general plan of training outlined in this memorandum should be regarded as applying, in principle, to the male student.

IV. SUMMARY OF RECOMMENDATIONS

Preclinical Training

All candidates for training in nursing should be required to complete successfully a preclinical course before admission to hospital training.

2. The preclinical course should include: (i) the basic sciences: elementary instruction in anatomy, physiology, normal psychology (human relations), hygiene and preventive medicine, chemistry, and dietetics; (ii) first aid and home nursing; (iii) the work of nursery schools and nurseries; (iv) environmental conditions—the work of the almoner's department; (v) the theory and practice of nursing and the relation of the nurse's work to the social economy as a whole; and (vi) introduction to hospital.

3. For students wishing to remain at school up to the age of 18 the preclinical training should form part of a two years' educational course begun at the age of 16 and open to all suitable candidates, whether or not they have gained a School Certificate.

4. The preclinical training should be available in evening classes, particularly for the benefit of girls who have left school before the age of 16.

5. The preclinical training should be provided also in training schools within the hospital system, the existing preliminary training schools being adapted for use as preclinical schools, and the course occupying a period of 16 to 23 weeks.

6. Candidates who take the preclinical course at a grammar school or in evening classes should be transferred to a hospital training unit for four weeks' continuous training in the third year.

7. Through the Ministry of Education and the Ministry of Health, maintenance grants should be provided where necessary for preclinical students.

8. The student's ability to undertake a career in nursing should be reviewed at the end of the preclinical course, and a certificate should be awarded by the General Nursing Council to those who have completed the course successfully.

The Common Hospital Training

9. The preclinical training should be followed by a common hospital training of an essentially practical character, which should carry the student up to the standard required of the enrolled nurse. This should occupy 69 weeks, the preclinical and common hospital training together covering a period of approximately two years (including an allowance of 12 weeks for vacations).

10. The content of the common hospital training in a general hospital should be as follows:

(i) *Medicine*.—Out-patient departments and medical wards, including the psychosomatic approach to medicine, dermatology, and the care of the chronic sick.

(ii) *Surgery*.—Out-patient department, surgical wards, and operating theatre, including gynaecology, orthopaedic surgery, ophthalmic surgery, and surgery of the ear, nose, and throat.

(iii) *The Work of the Casualty Department*.

(iv) *Paediatrics*.—Out-patient departments and children's wards.

11. A total period of 53 weeks should be devoted to medicine and surgery, the minimum time allocated to each department being 15 weeks. Of the remaining 16 weeks, 12 should be allocated to paediatrics and 4 to the casualty department. An equal division of time between medicine and surgery is the ideal, and the period devoted to each of these subjects should be longer than 15 weeks whenever possible. This period is suggested merely as the bare minimum.

12. Where necessary, the students should be transferred to a children's hospital for 12 weeks for the training in paediatrics.

13. The common hospital training should be provided also in paediatric training schools. These schools should continue to recruit their own students, who should be transferred for 12 weeks, on an exchange basis, to a general hospital.

14. Suitable mental hospitals, the major isolation hospitals, and sanatoria should be included among the parent hospitals in the scheme of common training, the students being transferred as necessary to associated hospitals for training in paediatrics and additional training in medical and surgical nursing. The arrangements must be flexible and should aim at a minimum of migration.

15. Students should be examined at the end of the two years' common training. The examination should be held under the auspices of the General Nursing Councils, but reports on practical ability from the parent hospital should be taken into account. A student who passes the examination should be awarded a certificate and accorded the status and title of "nurse" (her statutory designation being "enrolled nurse") whether or not she intends to undertake a more advanced training. She should be regarded as qualified for nursing employment under supervision.

16. As an exception to the general rule of a common training, the Tuberculosis Association Certificate should continue to be available to students who, because of physical disability, are unable to undertake a general training; and also, as a temporary measure, to able-bodied candidates who have not received the common training.

The Third Year of Basic Training

17. For students proceeding beyond the first two years of training there should be a further year's course leading to an examination qualifying for State registration. Practical training should be combined with more advanced theoretical instruction in the third year.

MAY 29, 1948

SUPPLEMENTARY REPORT OF COUNCIL

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL 143

18. The content of the third year's course for a student whose parent hospital is a general or a paediatric hospital should be as follows, the order in which the subjects are taken being optional:

(i) <i>Psychiatry</i> (Training and residence in a mental hospital)	12 weeks
(ii) <i>Infectious Diseases and Tuberculosis</i> (Training and residence in a hospital for infectious diseases and a sanatorium)	12 weeks
(iii) <i>Obstetrics</i> (Antenatal and post-natal clinics The normal puerperium)	6 weeks
(iv) <i>General Training</i> (Completion of general training in the parent hospital)	12 weeks
(v) <i>Public Health</i> (Introduction to the field, including health visiting and district nursing)	4 weeks
Vacations	6 weeks
Total	52 weeks

Specialization

19. The certificate issued by the qualifying body at the end of the three years of basic training—whether the parent hospital has been a general or a special hospital—should be in respect of the general training and a diploma in any special branch of nursing should be awarded only to the nurse who has undergone further training after State registration. Suitable post-registration diploma courses should be provided for those nurses who wish to become specialists.

Male Nurses

20. In principle, the whole scheme of training should be regarded as applying to male as well as to female nurses, and all appropriate conditions made nurses or midwives eligible equally with female nurses for promotion to posts of responsibility.

ADDENDUM BY THE BRITISH HOSPITALS ASSOCIATION

The British Hospitals Association is in agreement with the proposal that preclinical nursing training should be included within a general education for girls at grammar schools from reaching age 16, to which assistance is made in many parts of the association, however, it is not possible to make this recommendation goes far enough in the matter of the figures and the fact to be met, since a large number of the girls who are training cannot be recruited from the patient numbers from the nurse alone.

It is understood that the total number of girls leaving school annually is approximately 250,000. Of these only 12,000 leave grammar schools at the age of 17, 18, and no fewer than 10,000 leave secondary grammar schools at the age of 16. The first category (forming the 12,000) has to be met by the nursing profession, and the second category (forming the 10,000) has to be met by the nursing profession and the medical profession. Teaching and other professions are not in a position to meet the full demands of the nursing profession, and the medical profession must also draw heavily upon the second category of 10,000 who leave at age 17. In consequence and with the difficulty of "bridging the gap" there is but a small residue from this source with which to increase recruitment to the nursing profession unless schemes can be devised which will enable a larger proportion of the second category to be employed—e.g., in day nurseries, child nursing, etc.—with partial continuation of general education and pre-clinical nursing training. As a fact seems, but all too few authorities have experimented with these lines, with results which fully justify development in the whole country. In this respect the position of the second category (the 25,000) is closely allied with that of the third (the 210,000 who leave at age 15 plus).

School leavers in this third category for the most part find full-time employment from age 15 plus onwards, and by the time they have reached age 18 either are loath to give up remunerative occupation, in which they have prospects of further advancement, or regard their employment as a means of living until marriage. In either case there is little inducement for them to undertake a completely new training for a new profession.

From this it is clear that the key to the problem is to provide schemes whereby suitable girls in this category can be provided with partial employment—e.g., in day nurseries, clinics, nursery schools, etc.—together with continuation of general education, including preclinical nursing training, for example, in day continuation schools, the pre-clinical training being linked, wherever possible, with a hospital Pre-nursing Training School) so as to give them an incentive to pass the entrance and subsequent nursing examinations and at the same time secure their interest in nursing as a career.

The very important source of supply provided by secondary modern schools must no longer be neglected, and the interest of as many girls as possible must be directed to the nursing profession if the urgent problem of the shortage of nurses is to be effectively countered.

The Association feels that these proposals merit serious and urgent consideration on a national basis, and the Minister of Health and the Minister of Education jointly should find a very wide field for experimentation within the limits of local factors and circumstances, and have already been put into operation successfully in varying forms by the authorities in some areas.

APPENDIX VI ENURESIS

Memorandum Prepared by the Joint Committee of the B.M.A. and Magistrates' Association on Psychiatry and the Law

1. This memorandum has been drawn up by a Joint Committee of the British Medical Association and the Magistrates' Association. It is put forward in the hope that it may be of interest and assistance to those responsible for the care and treatment of children and adults who suffer from enuresis.

2. Although enuresis is essentially the same condition in adults as in children and the one is usually continuous with the other, there are certain differences which suggest that the problem as affecting the two ages should be presented separately. Enuresis as affecting children and adults is therefore dealt with in different sections and a third section is given to general conclusions.

I. ENURESIS IN CHILDREN

Development of Control

3. The bladder of a newborn baby empties itself by reflex action. The control is automatic and centred in the spinal cord—the brain takes no part in the control and a baby therefore resembles a patient with a divided spinal cord. As the baby's nervous system develops, the nervous impulses from the bladder are relayed to the sensory centre in the mid-brain. He is now conscious of the state of fullness of his bladder, but though aware of this the toddler tends to act impulsively or receiving the signal "full."

4. In the next stage of development the messages from the mid-brain sensory centre are relayed to the grey matter of the highest level of the brain and control of the impulse to empty the full bladder becomes possible. With this acquired control it is possible to train the bladder to hold more urine and to empty it at times convenient to parent or guardian. This acquired skill of retaining urine becomes by repetition and practice a habit which persists even in sleep.

5. By the age of 3 the normal toddler should be dry at night—his control is no longer centred in the lower part of the spinal cord, but in the grey matter at the highest level of the brain.

Causes of Failure of Control

6. If all children who wet the bed at night to a significant degree after the age of 3 are to be considered as enuretics, it has been estimated that about 1 in 7 of the total population have at some time suffered from nocturnal enuresis.

7. Of nocturnal enuretics probably less than 1 in 10 wet the bed because physical abnormalities interfere with control. At one time it was thought that variations in the development of the bones of the spine were associated with enuresis, but recent investigations have demonstrated that these abnormalities in the fusion of the spinal vertebrae are as common in normal persons as in enuretics.

8. It has been estimated that 6% of enuretic children wet the bed because they have never been properly trained. They have been brought up in very poor homes with the minimum of bedroom equipment, and inaccessible lavatories, by mothers who are themselves so feeble and limited that the children have never been disciplined in that practice and repetition in controlling their bladders which leads to sound habit formation. But these two factors of physical abnormality and faulty training do not account for more than 15%. The great majority of enuretics (85%) are considered to be suffering from disorders of function.

Defective Control by the Brain

9. Physiological experiments carried out on these enuretics demonstrate that the failure is not in the spinal cord centre, or even in the mid-brain, but in the development of top-level control. Either this control by the cells of the grey matter may never have developed or it may have developed but have been disturbed, or in some individuals the innate defect is such that the achievement of sustained control by the grey matter is impossible.

10. In the second alternative, factors such as fatigue, excitement, pain, and fear interfere with potential control. Characteristically, the child has been dry and then control breaks down and bed-wetting begins again. The complex emotions stimulated by the arrival of a younger brother or sister, the fears and anxieties that follow separation from the parents, the pain following operations or accidents, may be sufficient to throw out of gear the relay system of nervous impulses between the centre of feeling in the mid-brain and the controlling areas in the grey matter.

11. The third alternative—namely, the impossibility of sustained and persistent control by the grey matter because of defects in the controlling centres—probably accounts for a large number of enuretics, especially that hard core of about 8% which resists all treatment. Most of these have wet the bed continuously from infancy; control has never been established; and the hypothesis that cerebral control is defective is supported when it is found that in this group is a high proportion of mental defectives, mentally retarded children, and psychopathic personalities.

12. That this failure of development of control is due to a defect in the highest centres of the brain, and that it is an inherited failure, is supported by the fact that in the family of each persistent enuretic on an average two other enuretic members can be found. Moreover, surveys have shown that emotional instability or social maladjustment is very frequent among the relatives of enuretics.

13. Enuresis sometimes shows itself as the first symptom which may indicate a more general failure to control impulses, and it may be found that the boy who has been reported as a bed-wetter may also be unreliable and impulsive in other ways. In other instances bed-wetting accompanies asocial impulses to pilfer, to damage wilfully, and to behave aggressively to other individuals. It is not surprising, therefore, that a proportion of delinquents should be enuretic, and it has been observed that when it does occur in such subjects it is much more persistent. The same lack of control is evident socially in their behaviour and physiologically in their bed-wetting. Nevertheless, in spite of this relationship between enuresis and delinquency it must not be assumed that all persistent enuretics are delinquent or unstable; indeed, there are many enuretics, both children and adults with a long history of bed-wetting.

14. To exclude enuretic delinquents from foster-homes, approved hostels, and homes is to turn away those members

of the community most in need of skilled environmental control. In the nature of things sufferers from this complaint must be expected in these places and provision should be made to deal with them.

Treatments

15. The multiplicity of treatments that have been tried for enuresis is sufficient evidence of the difficulty of the problem.

16. Certain drug treatments have been used with varying success and these are mentioned later, as also are certain devices and variations of daily routine and habit; but it is certain that there is no short cut to victory by any one method alone. There is no doubt that some of the failures in the treatment of enuretics have been due to too much concentration on the organ—the bladder—and the neglect of the person to whom the bladder belongs. Likewise, some of the successes claimed for a particular drug or method of treatment have in large measure been due to the personality of the foster-parent, warden, headmaster, or doctor employing the method. Confidence in the successful control of his symptom is the basis on which the enuretic child can identify and accept the control which by himself he cannot achieve.

17. The child should be examined by a doctor in order that any physical abnormalities or organic disorders may be detected and corrected. Sometimes the cure of a persistent infection of the urinary tract may be necessary. The large majority of cases, however, are due to a disorder of function, and in the treatment of these persistence and patience are necessary.

18. The parents or whoever may be responsible for the cure of the enuretic must first of all be instructed in the essential nature of the complaint. Where it seems that higher standards of cleanliness, discipline, and regularity are required in the home, parents should be educated to try to achieve this. The well-brought-up child is usually keenly sensitive about his bed-wetting, and punishments, scolding, and shaming should not be used against him as they are likely to aggravate fear and vengeful feelings and make conscious control more difficult. On the other hand rewards for success and incentives are frequent of value, particularly in intelligent, ambitious children. Often the bed-wetter is prevented from going to camp, visiting friends or joining a club because of his disability, and the prospect of being able to take part in these things when habitually dry often helps considerably to this end. A record chart showing the number of dry nights provides positive evidence of the possibility of control and has been known to be helpful. Above all the child must be helped in his emotional and social adjustment, and both he and those responsible for him must be made to realize that wetting is not a crime or an indication of baseness, and the feeling of hopelessness of cure must be dispelled. This hopelessness is often fostered by the all too common popular notion of the inevitableness of a "weak" bladder or "weak" kidneys.

19. Psychological treatment of enuresis is likely to be successful in those cases that have established control and subsequent broken down as the result of pain, or fear, or other emotional disturbance. Psychological treatment is less likely to help those who have never established control. In this connexion it is interesting to note the sex differences in enuretics. There are many more enuretic boys than girls, and girls respond, on the whole, much more rapidly to treatment.

20. A patient and careful inquiry into the social and environmental history of enuretics is always worth while and sometimes reveals a clue which leads to cure. This is well illustrated by a particular case in an institution of a boy whose bed-wetting had persisted for a year. Research showed that the trouble started when he was seven, and its onset coincided with his mother's second marriage to a brutal drunkard who immediately started to ill-treat his wife and disturb the home. It appeared probable that the lad's bed-wetting started as a result of being awakened at night by his noisy stepfather, and that incontinence due to fright persisted. This was explained to the boy, and he was told that since his stepfather was dead and the original cause removed his trouble should now cease. It did.

21. It is hard to assess the effect of drug treatments, since a psychological factor enters into the situation and the result often due to the personal influence of the doctor rather than to drug used. Nevertheless there is a place for drugs, especially

those which relieve spasm in the muscles concerned, such as belladonna, and those which diminish nervous tension, such as the various sedative drugs. Ephedrine and benzedrine have been tried with a view to increasing the efficiency of the control over the relay systems in the brain itself and so make the enuretic more aware of the sensations from his internal organs. Whether control is improved by this enhanced awareness is not proved.

22. The deprivation of fluids as a treatment seems, on the whole, to be unsuccessful, and restriction of fluids should never be for longer than three weeks. In any case it does not solve the problem of training the bladder to hold more. Thoroughly awakening the child to empty the bladder half an hour before the usual time of wetting has been found effective in many cases. After about a month, if in his own home, an alarm clock can be used to do the rousing. The enuretic is generally a heavy sleeper and is not easily trained by regular calling at night to awake himself to attend to his needs; he will, in effect, remain dependent upon the person who wakes him to control his bladder for him. Nevertheless, this method does enable many persistent bed-wetters to be relatively dry and thus improves their outlook and relations with others around them, and also it does serve to tide many intermittent enuretics over a bad spell. It is a method which has been found useful in many approved schools. Many schools have also reported the beneficial effect of a heated dormitory. Segregation in schools is not recommended, as this stimulates shame and casts a slur and thus makes matters worse by increasing anxiety over the symptom. What is needed is the minimum of fuss and unobtrusive reassurance.

23. The use of a rubber bag worn inside the leg of the pyjamas at night has sometimes been found to give confidence to the enuretic patient so that in time he has been able to discard it.

24. In spite of every effort of treatment there is bound to remain a hard core of incurable bed-wetters, and neither they nor those in charge of them can be blamed. In these cases everything possible must be done to mitigate the nuisance and to make life tolerable both for the patient and for those with whom he lives.

II. ENURESIS IN ADULTS

25. Although there is a marked general tendency for enuresis to lessen with age many adult enuretics exist. In nearly all cases the condition was present in childhood.

26. They fall into the same groups as children, but the majority belong to those groups for whom cure or even alleviation is difficult and sometimes impossible.

General Examination

27. Physical examination by a doctor should be a routine practice. Some adult cases are due to the defects in the brain mentioned in the description of young bed-wetters, and these cases are best dealt with by the methods described. There is also a group, small in numbers but important to discover, where there is a physical cause for the condition in the sense of actual physical disease or injury. The conditions involved are by no means restricted to the excretory organs. Indeed, enuresis may be an early sign of such a serious illness as disseminated sclerosis, which is a disease of the spinal cord and brain. The existence of a relevant physical disease or injury cannot be ruled out because there is a history of bed-wetting in childhood or even of continuous enuresis from childhood. It can be assumed, though, that when this symptom has not occurred until adult life a physical cause is highly probable if the patient is sane. In the elderly the condition may be due to mental illness, but even so physical factors are overwhelmingly the commonest cause. Indeed, the mental illnesses involved are often of physical origin, such as arterial disease or degenerative processes.

Management and Treatment

28. In all cases due to physical disease or injury treatment of the symptom must centre round that of the physical condition in question. Nevertheless, the general management of such cases often involves many of the methods which are discussed below, with certain common-sense modifications.

29. Many adult bed-wetters have been persistent since childhood, but many have had long periods of freedom. In general the fact that there have been long free periods is a favourable sign and every effort should be made to find the reason for the relapse. The methods that produced improvement earlier should be discovered and their present usefulness considered. Physical factors, as already mentioned, may cause the relapse, but far more often it is due to emotional stress. This may take the form of domestic worry, a nervous breakdown, unsuitable environmental change—anything in fact that can upset a somewhat narrow or precarious adaptation to life. In such cases the remedy is either to help the person to adapt to his new circumstances or to help him to restore his earlier conditions. In practice it is a question of which is practicable, but the former is the better since it produces a more adaptable person and one therefore more able to cope with future changes.

30. For the majority of adult bed-wetters the cause of the symptom is either a psychological one or the kind of brain defect mentioned above, or a combination of both.

31. The measures used to effect cure in these cases include all those remedies mentioned as applying to children. Improvement is often slow and much patience is needed.

32. In the adolescent and the adult more use can be made of direct appeals to social standards, though this must not be overdone in the case of a sensitive or neurotic patient in whom the response is not rapid. A good guide in relation to this is the degree to which he is ashamed of the habit. If he is really ashamed of it, it is unlikely that further stimulation of this feeling will help. If he is not, he needs to be educated firmly, albeit kindly.

33. There is a real need for caution about what may be termed disciplinary or punitive measures. It is fatally easy to assume that they succeed, and results must be checked and followed up for a year or two to assess the efficacy of the methods used. For example, it is often alleged that an enuretic soldier can be cured by making him sleep in an upper bunk, when his habit annoys the man below, who will "make him better." In some cases this practice produces results usually temporary, but never in the kind of person who would not benefit equally or to a greater extent by a less distasteful method.

34. Bladder control can sometimes be improved by encouraging the patient deliberately to restrain himself from passing water when he first feels the urge to do so. With persistence and practice this deliberate voluntary control results in decreasing sensitivity so that there must be a much larger quantity of urine in the bladder before any imperative desire to pass water is experienced.

35. Needless to say, as with most of these methods, medical supervision is needed.

36. It appears that good results follow an intensive course of treatment based partly on the psychological methods of persuasion and re-education, and partly on the physical methods of training the bladder (small or large) to contain large quantities of fluid injected by catheter without arousing any strong desire to pass water. Those who benefit most are young adult men of good personality who have had symptom-free periods spontaneously at some time in their lives. Men in this group are usually good workers and desirable citizens within the limits set by their capabilities. Unfortunately there is a high relapse rate under stress of ordinary life, though it seems probable that at least one-quarter of the recoveries are of lasting value.

37. Young women tend to respond better than men to persuasion and re-education, though statistics are not available.

38. A thorough search for causes, with medical aid, followed by a good all-round attack on the habit is needed. This attack includes environmental change, social education, medicines and other physical methods, appropriate psychological handling, and the education of both the enuretic and his associates on the lines indicated below.

39. The doctor is the obvious person to decide on the plan of campaign, though until knowledge is improved he will not always be right, but he will be able to help matters materially in many cases.

40. In the Army in wartime experience of the treatment of adults was disappointing, but in civil life better results can be expected, since environmental change is less limited and the

prolonged interest of one doctor more practicable. The family doctor is the adviser *par excellence*, but the psychiatrist will often be needed also, either for more intensive psychological treatment or to assist in diagnosis.

41. The outlook varies with the cause, though it is always better if there have been long periods when the symptom was absent. Three groups are deserving of special mention: (i) Those where mental defect is a serious factor; (ii) those who show a chronic maladjustment to life; (iii) those with good stable personalities, even though intelligence may be on the low side or though there may be some degree of neurosis present.

42. The last type gives the best results and is always worth prolonged effort.

43. The other two groups are far less hopeful and may not respond unless their mental defect can be very fully allowed for in their treatment and general management or the cause of their chronic maladjustment lessened in intensity—e.g., a neurosis alleviated or an awkward personality trait dealt with satisfactorily. Clearly these groups will need more psychiatric advice and handling than the third one, but the psychiatrist will often be attempting the impossible.

44. Occasionally adult enuretics are seen who appear never to have been adequately trained to regard such a habit as undesirable and who passively accept it. They need firm training, but they are so often subnormal in other respects that it is not surprising that failure is so frequent.

III. GENERAL CONCLUSIONS

45. Pessimism is not a good mood in which to approach the bed-wetter. Nevertheless it must be realized that many bed-wetters are persistent whatever is done. Even so, there is no need to be too pessimistic. An appreciably larger number of adult bed-wetters were referred for advice in the Services during the war than in civil life. There is need for follow-up of Service cases, since ultimate history of such patients is not really known. It does seem likely, even allowing for the existence of families where the habit is tolerated to some extent, that in the freedom of civil life, or in the protected life of those in institutions, the habit does frequently come at least within bearable limits. So it is worth while to persist in the attempt at cure and to persist in palliatives and educative measures even when cure is not achieved.

46. The chronic incurable cases deserve sympathetic understanding, and their lot, and that of those who live with them, can be made much happier by this and by the habitual use of bag urinals for night wear, mackintosh sheets, and so on. Full use should also be made of sedatives and other drugs and of any measures that will lessen anxiety.

47. It is amazing how often these simple methods for avoiding much of the nuisance caused by enuresis are neglected. It seems there is a real need for those who deal or live with chronic enuretics to guard against virtual neglect of the sufferer, especially when the habit annoys them.

48. At present, extra rations of cleaning materials are only allowed on a medical certificate that the condition is due to physical causes. In incurable cases and those where lack of cleaning materials makes cure harder this is unfortunate, since the cause is not often physical in the literal sense of a physical illness or malformation. However, it is open to individual opinion how far the condition of bed-wetting can be regarded as of physical origin in the sense of, say, a congenital cerebral defect, and many doctors would consider that cases did fall in this way within the conditions laid down by the Food Ministry. This consideration applies to persistent bed-wetters in all groups.

49. It is clear that training is needed both for the patient and those who live with him. It should be given with due understanding and an adequate recognition of the futility of punitive measures. Since many chronic cases are of low intelligence, training must often be given with very great patience, simplicity, and persistence.

50. Those who live with a bed-wetter often have a hard fight with their own annoyance, anxiety, and shame in the matter, and the bed-wetter often needs to be informed of this and will be helped by realizing the attitude of those around him.

51. These measures all tend to diminish anxiety over the situation, and this in itself is a valuable aid in the treatment of the habit. Indeed, the alleviation of worry

in the home must receive attention, since it seriously aggravates enuresis whether the worry is about the habit itself or quite other matters.

52. Thus, whatever the method used, training should aim at teaching the patient and those who live with him everything that can be done to mitigate the nuisance caused. It should also aim at convincing all concerned that this is both a long while and necessary and so help them to acquire a spirit of toleration. This toleration must be mutual.

CONFLICT IN AUSTRALIA

The Federal Council of the British Medical Association in Australia has advised members to return the formularies and prescription forms sent out by the Federal Government and to continue to prescribe on private forms after June 1, when the scheme for free medicine starts. The Council maintains that doctors must be free to prescribe what they think best and not what the Government considers suitable.

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

Metropolitan Borough Councils.—Fulham, Hackney, Poplar

Non-County Borough Councils.—Dartford, Radcliffe (limited to future appointments), Tottenham, Wallsend.

Urban District Councils.—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Portslade, Redditch (restricted to new appointments), Tyldesley.

Scottish Burghs.—Motherwell and Wishaw.

Association Notices

SCOTTISH COMMITTEE

1948-9 Session

Election of three representatives by the Group of seven Divisions comprising Orkney, Shetland, Caithness and Sutherland, Inverness, Outer Islands, Ross and Cromarty, and Argyllshire.

In accordance with the Standing Orders of the Scottish Committee, nominations for these three vacancies shall be in writing and may be made (a) by a Division or (b) over the signature of not less than three members of the group. Nomination under (a) does not invalidate nomination under (b) or vice versa. Nomination forms have been sent to the Hon. Secretaries of the Divisions in the Group, and can also be obtained on application to the Scottish Office. If more than three members are nominated the election shall be by voting papers sent by post from the Scottish Office to each member of every Division in the Group. Nominations should be sent to me at the Scottish Office, 7, Drumsheugh Gardens, Edinburgh, not later than Saturday, June 12, 1948.

E. R. C. WALKER.
Scottish Secretary.

Diary of Central Meetings

JUNE

3 Thurs. Publishing Subcommittee, 11 a.m.

Branch and Division Meetings to be Held

METROPOLITAN COUNTIES BRANCH.—At B.M.A. House, Tavistock Square, London, W.C., Tuesday, June 1, 2.30 p.m. Ninetieth Annual General Meeting. Agenda: Report of Branch Council for 1947-8; report of Branch representatives on Central Council 1947-8; election of officers for 1948-9; address by incoming President.

PORTSMOUTH DIVISION.—At Kimbells Corner House Restaurant, Commercial Road, Portsmouth, Tuesday, June 1, 8 p.m. for 8.30 p.m. Dinner. 9.30 p.m. Annual general meeting.

THE LIPOTROPIC FACTORS IN EXPERIMENTAL CIRRHOSIS

BY
E. A. SELLERS,* M.D., Ph.D. C. C. LUCAS, M.A.Sc., Ph.D.
AND
C. H. BEST, C.B.E., M.D., F.R.S.

(From the Banting and Best Department of Medical Research, University of Toronto)

[WITH PHOTOGRAPHURE PLATE]

The term "lipotropic" was introduced by Best and Ridout (1935) to describe substances which decrease the rate of deposition and accelerate the rate of removal of hepatic fat. This definition has now been broadened to embrace other established effects of dietary choline or its precursors. These include the prevention of renal lesions (Griffith and Wade, 1939) and of cirrhosis in experimental animals.

The production of cirrhosis in rats and dogs by dietary means afforded a new experimental approach to the study of liver disease (György and Goldblatt, 1939; Chaikoff and Connor, 1940). In rats it was shown that cirrhosis could be produced by feeding, for an extended period, a diet low in protein and devoid of choline. The appearance of the cirrhotic changes could be delayed or prevented by adding choline or its precursor methionine to the offending diet (György and Goldblatt, 1941; Webster, 1941; Daft, Scorell, and Lillie, 1941; Blumberg and McCollum, 1941).

These observations aroused the interest of many clinical groups, and in the last few years methionine, choline, inositol, and combinations of these substances have been tested in the treatment of chronic liver disease. Owing partly to the inherent difficulty of controlling clinical studies adequately, and partly to the fact that the basal diets contained large and perhaps optimal amounts of the lipotropic factors, the results obtained are difficult to assess. In cirrhosis, especially that associated with alcoholism, it has been reported by a number of investigators (Russakoff and Blumberg, 1944; Barker, 1945; Beams, 1946, and others) that the addition of choline to the diet exerts a favourable clinical effect. The failure of this treatment to produce any beneficial result has also been reported (Yater, 1943; Man, Kartin, Durlacher, and Peters, 1945; and others).

It is well established that in animals in which cirrhosis has been produced by certain chemicals the hepatic lesions may disappear when the administration of the toxic agent is discontinued and a normal diet is supplied. It should be appreciated that most diets (whether for human subjects or experimental animals) which contain a large proportion of natural foodstuffs will provide adequate amounts of the lipotropic agents.

Cameron and Karunaratne (1936) observed that in cirrhosis produced by carbon tetrachloride extensive

regeneration of liver cells and return to a normal configuration occurred within a few weeks after the administration of carbon tetrachloride was discontinued. Edwards and Dalton (1942) made similar observations on the regression of the cirrhotic process in the livers of mice receiving carbon tetrachloride when its administration was stopped and a normal diet provided. Lowry *et al.* (1941, 1945) found that when rats with dietary (choline deficiency) cirrhosis were treated with choline, or given a high casein diet, removal of fat from the liver occurred and extensive regeneration of liver cells took place. Comparative studies on the influence of the various lipotropic agents in the repair of cirrhotic lesions produced by carbon tetrachloride have not hitherto been reported.

The results of the present studies demonstrate again the importance of the lipotropic factors in the repair process, and serve to indicate the relative merits of dietary protein, methionine, choline, and inositol, alone or in combination, in the treatment of carbon tetrachloride cirrhosis in albino rats under certain experimental conditions.

Production of Cirrhosis.—Cirrhosis produced by prolonged administration of carbon tetrachloride has some advantages for this type of study. It can be produced consistently and relatively rapidly, and resembles human portal cirrhosis in many respects (Lamson and Wing, 1926; Moon, 1934). In our first series of experiments the cirrhosis was produced by exposing rats to carbon tetrachloride vapour, and in the second by administering a solution of this substance orally.

Experiment 1

Male white rats (average weight 136 g.) of the Wistar strain were exposed to an atmosphere containing approximately 1,000 p.p.m. of carbon tetrachloride for four hours a day, five days a week, until moderate cirrhosis had been produced. This usually required from 25 to 35 exposures. The capacity of the exposure chamber was approximately 1,000 litres, and an air flow of 250 to 300 litres a minute was maintained.

The rats were kept in group cages and were supplied with a commercial stock diet ("purina fox chow") and fresh water. The 164 animals surviving the exposures were divided into 13 groups. One group of 20 animals was sacrificed immediately to provide initial histological and chemical data. One group (seven animals), to serve as a control, was placed on a hypolipotropic basal diet containing gelatin 12%, casein 8%, and

*Now in the Department of Pharmacology, University of Toronto

dripping 10%, corn oil 2%, salts 5%, cellu flour 2%, vitamin powder 1%, sucrose 59.75%, cod-liver oil concentrate 0.015%, cystine 0.24%. This amount of cystine was added in order to make the total organic sulphur content approximately equivalent to that of a diet containing 20% casein.

The vitamin powder was of such a composition that the intake per 10 g. of diet was as follows: thiamin hydrochloride 50 μ g., riboflavin 25 μ g., pyridoxin hydrochloride 20 μ g., calcium pantothenate 100 μ g., and niacin 100 μ g. The cod-liver oil concentrate supplied at least 300 i.u. of vitamin A and at least 75 i.u. of vitamin D per 10 g. of diet.

Ten different diets were prepared by adding to the basal ration various lipotropic supplements, as listed below. The quantities stated are the amounts in grammes per 100 g. of final mixture, the supplements in each case replacing an equal weight of sucrose in the basal ration: (1) casein 7, arachin 5, fibrin 3; (2) casein 7, arachin 5, fibrin 3, choline chloride 0.3; (3) casein 30; (4) casein 22, arachin 5, fibrin 3; (5) choline chloride 0.3; (6) methionine 0.9; (7) inositol 0.3; (8) choline chloride 0.3, inositol 0.3; (9) methionine 0.9, inositol 0.3; (10) choline chloride 0.3, inositol 0.3, methionine 0.9. There were 20 animals in Group 5, seven in Groups 3, 4, and 6, and 13 in all the others.

A final group (20 animals) continued to receive the laboratory stock diet (purina fox chow), which is referred to as Diet 11. All diets, with the exception of the last-mentioned, were essentially isocaloric. While receiving dietary treatment the animals were kept in individual cages. Each rat was offered 15 g. of the appropriate diet daily and the actual food consumption was recorded. When the average daily food intake of the group which ate the least (Diet 7) fell to 13 g. a corresponding reduction was made in the food offered to the other groups. After three weeks, and at intervals for the succeeding nine weeks, three or more rats from each group were sacrificed and their livers were removed for chemical and histological examination. Extraction and analysis of liver lipids were conducted as described by Best, Lucas, Patterson, and Ridout (1946).

Experiment 2

A 20% solution of carbon tetrachloride in corn oil was administered to female white rats (average weight 160 g.) of the Wistar strain two or three times a week over a period of four months. A dose of approximately 0.2 ml. of the solution was given to each animal by stomach-tube. During this phase of the experiment the rats were kept in group cages and were offered the stock diet and water ad libitum. They were then divided into five groups of 10 rats each, and one group was sacrificed immediately to secure initial values. The remaining groups were placed on rations the following components of which were common to all four diets: beef dripping 10, corn oil 2, cellu flour 2, salt mixture 5, vitamin powder 1, cod-liver oil concentrate 0.015. After the addition of the supplements listed below, sucrose was added to bring the mixture to 100 parts: Diet 21 contained casein 10%, cystine 0.2%; Diet 22, casein 10%, cystine 0.1%, methionine 0.1%; Diet 23, casein 20%, cystine 0.2%, methionine 0.2%; Diet 24, casein 10%, cystine 0.1%, methionine 0.1%, choline 0.3%. Four rats from each group were sacrificed after two weeks and the remainder after 13 weeks on the test diets.

Results of Experiment 1

In the group killed immediately after exposure to carbon tetrachloride considerable variation in the gross appearance of the liver was observed. Most of the livers were coarsely but evenly granular (Plate, Fig. 1), of a yellowish-brown colour, and of a rubbery consistency. Microscopically, wide bands of fibrous tissue separated the liver cells into pseudo-lobules with a visible central vein. No normal lobular structure was discernible. Some cells were laden with fat, while others showed signs of fatty degeneration (Fig. 2). Cellular necrosis, haemorrhage, and haemorrhage into the parenchyma were present (Fig. 3). Groups of liver cells with mitotic figures were seen in many lobules. The average fat content, estimated by the method of Folch, Lees, and Sloane, was 6.4% of the wet weight. In the group killed three weeks after exposure to Sudan IV the amount of fat

visible suggested a greater deposition of lipid than that demonstrated by chemical analysis.

The livers of rats maintained on the hypolipotropic basal diet became very fatty (20 to 30% of wet weight), and all but one of the animals died within three weeks. The surviving animal, which was sacrificed at three weeks, also showed extensive cirrhotic changes. The kidneys of all these animals showed the dilated tubules and atrophic degenerative "nephrosis" commonly seen in older animals receiving hypolipotropic diets (Hartroft, 1948). When choline (0.3%) was added to the basal diet, either alone (Diet 5) or in combination with the other supplements (Diets 2, 8, and 10), fat disappeared from the liver and a remarkable regeneration of liver cells took place. In rats killed after three weeks on these rations (Diets 2, 5, 8, and 10), parenchymal cells filled the lobules, but only a few mitotic figures could be seen at this time. This probably indicated that maximum regeneration of parenchymal cells had already taken place. A number of circumscribed lobules of deeply staining cells were seen. The flattened cells at the periphery of these lobules produced a whorled appearance. Pressure due to the bands of fibrous tissue may have been responsible for this condition (Fig. 4). The fibrous strands were thinner but appeared to be stained more deeply than in the livers of the controls. This appearance was probably due to "condensation" of the fibrous tissue. In specimens secured after 6, 9, and 12 weeks gradual improvement was noted, so that latterly (12 weeks) the livers were normal in colour and consistency (Fig. 5). Microscopically, many sections of the livers were essentially normal in appearance (Fig. 6). When special stains for fibrous and reticular tissues were applied thin strands were seen forming a network around and through the lobules (Fig. 7).

Supplements of methionine (0.9%, Diet 6), or of a quantity of casein (30%, Diet 3) which added approximately the same amount of methionine, produced favourable and essentially similar results. Equally beneficial effects attended the use of the laboratory stock ration (Diet 11). The gross and microscopical findings observed on all these diets (Nos. 3, 6, and 11) resembled closely those described above for the animals receiving choline.

Supplementation with inositol alone (Diet 7) possibly had a favourable effect on survival of the rats. Although the growth was poor the mortality rate in the group receiving inositol was of the same order as in those receiving supplements of other lipotropic substances. However, with inositol the livers became very fatty (21 to 29%), as shown in Fig. 5 (lower right), and the extent of the fibrosis apparently increased. In the kidneys definite changes similar to those seen in animals suffering from subacute choline deficiency (Griffith, 1941; Hartroft, 1948) were invariably present.

In rats receiving the very high casein supplement (Diet 3) or the mixed protein supplement (Diet 4) the livers were larger than those of the group supplemented with choline alone but did not differ in other important characteristics. The high-casein diet (No. 3) contained about 1,260 mg. of methionine per 100 g. of diet.

A high-protein diet (No. 1), which was lower in methionine than Diets 3 or 4, produced less beneficial results. While the 15% supplement of protein (casein 7%, arachin 5%, fibrin 3%) made a total of 35% protein in this diet, it provided only about 670 mg. of methionine per 100 g. This amount permitted rapid growth, but the fat content of the livers of these rats rose to high levels while this was taking place. It was only when a plateau in the growth curve was reached that the level of liver fat decreased. At three weeks fat was distributed evenly throughout the lobule, but subsequently, as the fat content fell, distribution became limited to the region of the central vein. The livers were large, light brown in colour (Fig. 5, lower left), and firm to cut. Fibrous strands could be seen on the cut surface. It was not surprising, therefore, to find microscopically that fibrous tissue was present in larger amounts than in groups supplemented more adequately with the lipotropic factors.

In the groups receiving adequate choline or methionine (free or combined in protein) the normal columnar appearance of the liver cells was quickly restored, so that no apparent compression of bile canaliculi or sinusoids existed. In the groups not supplemented adequately these structures appeared to be compressed by cells containing fat. There was no evidence that

FIG. 1.—Cirrhotic liver of the type produced after 28 exposures of 4 hours each to carbon tetrachloride, 1,000 p.p.m.

FIG. 2.—Cirrhotic liver (H. & E. $\times 180$). Fibrous trabeculae separate liver parenchyma into pseudo-lobules one-half size of normal lobule. Some hepatic cells laden with fat.

FIG. 3.—High power of same cirrhotic liver (H. & E. $\times 700$) shows nuclear degeneration and a mitotic figure (M). Vacuolation of cytoplasm indicates site of fatty deposits.

FIG. 4.—Liver from rat on Diet 5 (hypolipotropic basal diet plus choline) after 3 weeks' dietary treatment. Lobule of irregular shape made up of hyperchromatic cells is illustrated. Fat has disappeared from hepatic cells and extensive regeneration has taken place. Decrease in fibrous tissue is already apparent.

FIG. 5.—Illustrates appearance of livers after 12 weeks' dietary treatment. Upper: liver normal in appearance, as from animals receiving supplements of choline or its precursors. Lower left: large pale liver with surface irregularity, from Group 1 (high-protein diet of relatively low methionine content). Lower right: fatty cirrhotic liver from Group 7 (inositol supplement).

FIG. 6.—Photomicrograph of liver of rat on Diet 5 (choline supplement, 12 weeks) (H. & E. $\times 370$). Vacuolated appearance of cytoplasm revealed by special staining to be due to glycogen; fibrous tissue scarcely discernible.

FIG. 7.—Liver from rat on Diet 5 (choline supplement, 12 weeks) (H. & E. $\times 370$). Liver stained to reveal fibrous tissue. Fibrous tissue can be seen in the illustration.

FIG. 8.—Appearance of livers of rats of Experiment 2 after dietary treatment for 13 weeks. Upper left: cirrhotic liver of rat fed Diet 21. Upper right: dietary methionine, increased but still inadequate (Diet 22), effects some reduction in liver fat but no improvement of cirrhotic condition. Lower left: protein supplement enriched with organic sulphur (Diet 23, methionine adequate) results in liver of normal size and colour but with slightly irregular surface. Lower right: liver of rat fed Diet 24 (i.e., Diet 22 supplemented with choline) appears normal.

the Chart the total liver lipids are seen to increase until a plateau is reached in the weight curve, after which a rapid decrease occurs. These data, and others to be published, suggest that when limited amounts of methionine are available it is used preferentially, but not exclusively, to meet growth requirements. The methionine content of this diet, which was insufficient for lipotropic action during the period of rapid growth, was adequate for removal of liver fat after rapid growth had ceased. While all essential amino-acids were present in Diet 1 in considerably greater amounts than are usually considered adequate, methionine was present in a proportionately smaller amount. Diet 1 contains about 670 mg. of methionine per 100 g., a quantity in excess of that usually accepted as optimal for growth. Since liver lesions persisted which would presumably have been eliminated by more methionine the amount supplied was obviously inadequate under these conditions. If sufficient methionine had been available to supply labile methyl groups for the biosynthesis of adequate amounts of choline the liver damage should have been repaired. Indeed, when choline was added to Diet 1 (Diet 2) the livers of the animals appeared normal on gross examination and nearly so microscopically. These observations illustrate the important nutritional interrelationship of methionine and choline, which will now be discussed briefly.

Methionine contributes to several metabolic requirements. The significance of the fact that these different metabolic roles exist is not always sufficiently appreciated. First, certain minimal quantities have been shown to be necessary, presumably as intact molecules, for maintenance and growth. Secondly, methionine serves as a source of organic sulphur for the formation of cystine and other sulphur-containing metabolites. Thirdly, it possesses a labile methyl group, and it is this characteristic which is of greatest interest in the study of lipotropic phenomena. Dietary choline cannot substitute for methionine in either of the first two roles. Thus in any diet choline can replace only that portion of methionine which is concerned with lipotropic phenomena; conversely, methionine supplements are not available for lipotropic purposes to a maximal extent until the first two (apparently more essential) roles of methionine have been filled completely. It would appear that in rats it is only under these conditions that dietary choline and methionine are maximally interchangeable. Moreover, not all dietary choline (or choline synthesized *in vivo* from dietary labile methyl groups) is used for lipotropic purposes, since it is obvious that some is utilized to satisfy structural and other needs. Only when the moieties of dietary choline and methionine that are used for lipotropic purposes have been assessed will it be possible to estimate a factor representing their lipotropic interchangeability in any diet. Similarly, cystine and methionine are interchangeable nutritionally to a maximal extent only when the minimal methionine requirement (i.e., as intact molecule) has been met and an adequate supply of choline (or dietary labile methyl groups) is present—i.e., when the deficiency involves only the supply of dietary organic sulphur. These interrelationships have recently become more clearly defined. Neglect to consider them has led to some confusion concerning the nutritional roles (particularly with regard to lipotropic phenomena) of choline, methionine, and cystine under different dietary conditions.

The apparent disappearance of fibrous tissue from the cirrhotic livers of animals which received the lipotropic agents deserves some further comment. After 12 weeks of treatment, in groups supplemented with choline or methionine, fibrous tissue could often be demonstrated only by special stains. Decrease in volume of individual lobules have accounted for much of this apparent disappearance, but the change from grotesque pseudo-lobula-

tion produced by the fibrous tissue to a more or less normal structure raises the question of actual removal of fibrous-tissue cells. This latter possibility is perhaps supported by the decrease in the number of nuclei of fibrous-tissue cells which can be seen. It should be emphasized that in our experiments the cirrhotic lesions which have been so strikingly affected by the lipotropic agents were of moderate degree and had not been present for long periods. A study of the action of the lipotropic agents on more advanced cirrhosis of long standing may be indicated, since clinicians are frequently confronted with this problem.

Certain potential clinical applications of the knowledge gained from the work on lipotropic factors, including that reported here, may be discussed briefly. Many clinical groups, stimulated in part by the findings of Patek and Post (1941), now use diets rich in protein and vitamins in the treatment of patients with cirrhosis. The favourable results which have been reported would appear to be attributable in large part to the occurrence of choline and methionine in these diets. We are not minimizing the obvious importance of inadequate amounts of minerals, other vitamins, and essential amino-acids. Estimations made in our laboratory and elsewhere show that normal diets may contain from 300 to 900 mg. of choline daily, and it may be calculated that the same rations would provide from 2 to 4 g. of methionine. If from one-fourth to one-third of this methionine were used for lipotropic purposes an additional 150 to 400 mg. of choline might be formed from it. Thus a normal diet may provide up to 1,300 mg. of available choline daily. The experimental evidence suggests that no beneficial effect in the treatment of cirrhosis should be expected from the addition of choline or methionine to a ration which is already adequately supplied with these factors—unless there should be interference with liberation of choline or methionine in the intestine or with the absorption or subsequent physiological actions of these compounds. No clinical conditions have yet been recognized in which the lipotropic actions of choline or methionine are inhibited, but this situation might conceivably exist in various diseases. However, there is convincing experimental evidence (Chaikoff, Entenman, and Montgomery, 1947) that interference with protein digestion by ligation of the pancreatic ducts or by removal of the pancreas decreases the liberation of methionine (and presumably the formation of choline). Excessive deposition of fat in the livers of duct-tied and insulin-treated depancreatized dogs has been observed repeatedly. In the depancreatized animals the progression of the lesion to cirrhosis has been followed (Chaikoff, Connor, Biskind, 1938). The clinician should therefore be on the look-out for signs of hepatic damage in cases of long-standing insufficiency of the external secretion of the pancreas.

Summary and Conclusions

Young adult rats in which a moderate degree of cirrhosis had been produced by the administration of carbon tetrachloride were placed on diets containing different amounts of the following lipotropic agents; choline, methionine, protein (containing methionine), and inositol.

None of the animals receiving only a basal hypolipotropic ration showed improvement in the cirrhosis. Deposition of fat in the liver increased, degenerative renal lesions appeared, and six of the seven rats in this group survived less than three weeks.

When adequate amounts of pure choline chloride or *DL*-methionine were added to the basal hypolipotropic diet a remarkable improvement in the gross appearance of the livers was noted within two or three weeks. After two or three months of this treatment the livers appeared normal, and on microscopical examination special stains were usually required to demonstrate any abnormal deposition of fibrous tissue. The

processes by which this fibrous tissue may disappear have been discussed briefly.

A high-protein diet, containing 35% protein but low in methionine, was not as beneficial as a ration containing 20% of similar protein to which adequate supplements of choline or methionine had been added.

A high-protein diet which contained an adequate amount of naturally occurring methionine produced results as favourable as those which were secured when suitable amounts of choline or methionine were added to diets of lower protein content.

While the experimental evidence indicates that the presence of the lipotropic agents is essential for the repair of the damaged liver under the conditions of our experiments, it does not suggest that the addition of choline or its precursor, methionine, to diets already containing adequate amounts of these factors will enhance the therapeutic effect unless some interference with the absorption or action of the lipotropic agents exists.

No evidence has been secured that inositol exerts a favourable effect on experimental cirrhosis.

On the basis of the experimental findings it is suggested that the favourable clinical results which have been obtained in patients with liver damage when an effective therapeutic diet is provided may be attributable in large part to the lipotropic factors which the diet supplies.

We wish to express our thanks to our colleagues Dr. Jessie H. Ridout and Dr. W. Stanley Harroft for their generous assistance in certain aspects of this work. The expenses of these studies were defrayed in part by a grant from the Banting Research Foundation.

When Mr. Bevan opposed the proposal to limit the opening of new pharmaceutical units it was dropped. "This half-hearted attitude does not augur well for the future," Mrs. Jean K. Irvine, President of the Pharmaceutical Society of Great Britain, told its annual general meeting. "The consequences remain to be seen, but one of the main causes of unsatisfactory conditions in pharmacy will continue to operate and, other things being equal, will have the same results." The proposal that the manager of a pharmacy as well as the owner should participate in the contract under the National Health Service had also not been further pursued, she said, when the Minister indicated his opposition. The manager was dependent on his employer for furthering his point of view, and it was not necessary to attribute a hostile attitude to employers to realize how unsatisfactory it was that approximately half the pharmacists taking part in the Service would be denied the status their qualification and responsibility deserved.

PNEUMOCONIOSIS OF COAL-MINERS*

BY

C. M. FLETCHER, M.D., F.R.C.P.

Director, Pneumoconiosis Research Unit, Medical Research Council

[WITH PHOTOGRAPHURE PLATE]

The investigations of the Pneumoconiosis Research Unit have of necessity had a practical or *ad hoc* bias. There are many fundamental points of pathogenesis, of physiology, of cellular pathology, and so forth which remain obscure in coal-miners' pneumoconiosis, but, initially at any rate, we have had to set these points on one side and to seek information in the light of which appropriate administrative action might be undertaken in order to deal with the vast human and economic problems caused by the disease.

In South Wales, by the end of 1945, 12,000 men had been certified and new cases were still being certified at the rate of 100 a week. Nearly two-thirds of them were under 50 years old; one-quarter were under 40. The majority were coal-hewers, the most skilled class of mine workers. They found themselves, at an age when family responsibilities are at their heaviest, cast out of their accustomed work, with no training for alternative employment, and with weekly compensation amounting at most to 43 5s. for an unemployed man with a wife and three children. If the man obtained work his weekly compensation was reduced according to his earnings. No special system of treatment or after-care existed.

Post-mining Employment

Our first investigations, carried out under the supervision of Dr. Alice Stewart, were directed to studying these social problems. We asked the Social Survey to assist us, and during February, 1946, they carried out an inquiry, by house-to-house visits, into the post-mining employment of a one-in-ten sample of all the men who had been certified in South Wales before January, 1945. We also obtained a full employment history from the men whom we invited to attend for the clinical and radiological examinations which will be considered later. Lastly, we instituted inquiries at factories which were employing men with pneumoconiosis† in order to study the industrial performance of these men.

Generalization concerning the re-employment of men with pneumoconiosis is difficult because of the wide variety of the types of case to be considered. They range from young men with minimal disability to elderly men who are breathless at rest. However, 86% of the cases fall between the ages of 30 and 60, when any man should have a job, and there are two other important factors common to nearly all of them. They have all spent their adolescent and early adult years in coal-mining, at which they have become skilled, but they have no training for other forms of skilled employment, and they are, by reason of their breathlessness, incapable of undertaking strenuous physical exertion.

Bearing these points in mind, we may consider certain relevant statistics concerning the post-mining employment of certified cases of pneumoconiosis. Chart IV shows the percentage of the men in the Social Survey's sample of certified cases of pneumoconiosis and among all insured men and boys in South Wales who were employed each year between 1936 and 1946. It will be seen that under

*The second Goulstonian Lecture, given at the Royal College of Physicians of London, on Jan. 15. Lecture I appeared in last week's issue.

†In this paper the word pneumoconiosis includes silicosis.

conditions of full employment, such as existed in South Wales in the later years of the war, nearly 70% of the certified men found work; but that in the pre-war years and again in 1946, when the Royal Ordnance factories and other wartime industries were closing down, only 30-40% were employed. The contrast between the effect of scarcity of jobs on the employment figures for cases of pneumoconiosis and on those for normal workmen is striking, but it must be remembered that the two groups have not been standardized for age.

CHART IV.—Percentage of men in S. Wales employed each year, 1936-46. The 764 certified cases of pneumoconiosis are a 1 in 10 sample of all cases certified before January, 1945.

because of ill-health or because of old age. Thus under conditions of full employment some 20% of men certified with pneumoconiosis desired work but were unable to secure it.

Chart V illustrates the problem of re-employment of cases of pneumoconiosis between 1937 and 1946 in another way. It concerns all the men who were examined clinically (see below) and who were certified before 1940. The cases have been divided into those over and those under the age of 50 at the time of certification, and within these age groups they have been further divided into cases certified as Stage 1 silicosis, and those certified as Stage 2 and 3 silicosis.† It will be seen that the older men were very much less often employed than the younger men, but that in neither age group did the disease stage at certification have such an obvious influence on employment. The intermittent nature of the employment obtained by many of these men is also shown, and the infrequency of employment before and after the war relative to the wartime years is again evident.

When we considered the types of jobs obtained by these men (Chart VI) we found, in the Social Survey's analysis, that they were largely labouring, pedestrian, and bench-work jobs. Among the men whom we examined clinically the jobs were classified into skilled, semi-skilled, and unskilled. It will be seen that only a small minority of the men obtained skilled work. Thus the greater part of these skilled ex-coal-miners had to be content with unskilled

work. The classification used by the Silicosis Medical Boards is the following. The first stage is defined as being characterized by radiologically appearances not less than the presence of nodular shadows, with or without an increase of hilum shadows, linear shadows, and emphysema, with or without impairment of capacity for work. The second stage is characterized by an increase in the area of nodular shadows and a tendency to the confluence of the nodular shadows, and the presence of some degree of impairment of capacity for work. The third stage is considered unnecessary to describe, but implies a condition equivalent to total incapacity for work. It is characterized by massive consolidation.

CHART V.—Employment from 1937 to 1946 among a group of men in South Wales who were clinically examined and who were certified before 1940. They have been divided into those over and those under the age of 50 at the time of certification, and into those certified as Silicosis Stage 1 (S.1), Silicosis Stage 2 and 3 (S.2 and 3). Each line represents the employment history of a single man. Blank portions = unemployed; solid portions = employed.

CHART VI.—Analysis of types of work performed by men in the Social Survey sample and in the clinical sample.

PNEUMOCONIOSIS OF COAL-MINERS

JUNE 5, 1948

work, and often with labouring, for which by reason of their disability they were least suited.

Only just over half of the men said that they regarded their present or most recent job as suitable. Among the remainder the most common objection was that the work was too heavy, with long hours and exposure to fumes and dust as the next most frequent objections.

The efficiency with which an ex-miner disabled by pneumoconiosis performs a job in light industry is not easily assessed—partly because of the great diversity both of the population under consideration and of the available types of jobs, which renders misleading a statistical analysis based on a small sample, and partly because of the difficulty of choosing any satisfactory quantitative measure of efficiency. Mr. Treasure, an economist working with the Unit, made an analysis of attendance records at two factories employing pneumoconiosis cases in light assembly, welding, and store-keeping, in which it was possible to make a comparison between groups of 50 cases of pneumoconiosis and 50 controls at one factory, and between groups of 24 and 50 controls at the other (Table IV). In both these factories the sick-

experience of men with pneumoconiosis as employees. The replies were strikingly uniform in expressing complete satisfaction with the performance of these men so long as they were not asked to undertake strenuous work or heavy lifting.

In summary and with some simplification our views on the post-mining employment of the certified case of pneumoconiosis are the following: If conditions of full employment or labour shortage can once more be reached in South Wales a high proportion of certified cases of pneumoconiosis will find employment. But the skilled jobs outside coal-mining will still be filled by men trained for them from their youth, and the lighter jobs in the factories, run by private industrialists who must cut their costs, will be filled by cheaper female labour. The man with pneumoconiosis will still be forced, as he was during the war, to take up unskilled work, which will as often as not be unsuitable chiefly because most unskilled work is heavy work. Some form of special provision must be made.

In October, 1945, a "working party" under the chairmanship of Mr. D. R. Grenfell, M.P., spent a fortnight in South Wales considering this problem. They recommended (Ministry of Fuel and Power, 1945) the building of ten special factories for light industries in which employers were to be encouraged to employ partially disabled cases of pneumoconiosis by being granted reductions in rent if they did so. In this way it was hoped that employment would be provided for 100 cases at each factory or for 1,000 men in all (out of a total number of 17,000 men to-day). Now, two years later, although all these factories are under construction, none has yet been completed, so that we cannot say whether the bait of rent reduction will be sufficient to obtain preference for cases of pneumoconiosis over female labour, and whether these ex-miners will be given a chance of developing a skill such as that which they developed in their former occupation and without which they will remain dissatisfied.

We fear that the man with pneumoconiosis will continue to stand at the end of the queue for the lighter and more skilled jobs unless some special scheme of retraining, and if necessary State-subsidized employment, are provided. The National Coal Board (1947) has expressed its intention of providing employment for its disabled employees in the ancillary industries of coal-mining, such as the making of mining machinery. This would be an ideal solution, but under present circumstances it is remote. It would, however, be possible to re-employ many certified men, even under existing legislation, in certain occupations within the industry both on the surface and even underground, but this possibility is not widely recognized, and little or nothing is being done at present to help the men in this way.

But no matter how good the provision of normal employment may be, a residue of some 20-30% of the men will remain unemployed, largely because they feel too old or too ill for ordinary work; and they will sit at home unproductively doing nothing, but "waiting for the undertaker," as they often say. We have observed a number of the older and iller men as in-patients. We have found how unhappy they are sitting at home all day doing nothing. They often live in precipitous streets along which a dyspnoeic man dare not venture. If you live in a house at the top of a hill, and if you cannot even manage a single flight of stairs without a pause, a bus at the bottom of the hill which might take you to work is beyond your reach. We have found these men surprisingly adept in learning simple handicrafts. One man, aged 56, breathless at rest, had done no work for six years before he entered our ward. He learnt leather work, and has made a profit of £30 in four months since his discharge by selling leather goods which

TABLE IV.—Average Hours Lost from Work during January to September, 1946, by Groups of Pneumoconiosis Cases and Normals (Treasure, 1948)

Ex-miner (healthy)	26.9	20
Control	34.4	19.8

Pairs of figures between which the difference is significant appear in black type

ness and unauthorized absence rates for the two groups were observed during the first eight months of 1946. It was found that men with pneumoconiosis had significantly higher unauthorized absence rates than normals; they also had higher sickness absence rates, though the difference here was significant only at one factory. In the factory where the larger groups were investigated the cases of pneumoconiosis could be divided into those receiving weekly compensation (whose level is reduced according to the level of earnings) and those who had settled their compensation for a lump sum. This comparison showed a significantly higher unauthorized absence rate in the former than in the latter group. This emphasizes the unsatisfactory consequences of a system of compensation which places a premium on idleness. That these differences were attributable to pneumoconiosis and not to the different industrial backgrounds of the workmen is suggested by Treasure's finding that at a large service stores depot a similar study of ex-miners without pneumoconiosis and a control group without mining experience showed no difference between the absence rates in the two groups.

Too much weight must not be placed on this small-scale study. Moreover, although a low absence rate from work is an important criterion of industrial performance it is not a measure of efficiency at work. Treasure also sent a questionnaire to 150 firms in South Wales asking for the employers' opinion of cases of pneumoconiosis as workmen. Replies were received from 92 firms, of which 44 had had

be made at home. We believe that there is a need for the organization of home industries either at local labour clubs or actually in the men's homes, by which these men might feel that they are making some contribution for the common good and that they are not outcasts, disabled in the winning of coal and now forgotten. An excellent example of this type of provision is set by the settlement at Maesyr-Haf, in the Rhondda Valley. It is an example which should be followed. There must be no atmosphere of State-run charity. We cannot ask men to enter the hazardous occupation of coal-mining unless we can assure them that proper provision will be made for their needs if they are disabled.

Radiological Progression after Certification

The social or economic problems which face men certified with pneumoconiosis cannot be considered in isolation from their clinical condition. We need information in order to guide us in the prescription of methods of treatment and rehabilitation, and we also need to know whether the disease is arrested or whether it continues to progress after a man has been suspended from underground work. Hart and Aslett postulated that progression from reticulation or major consolidation was associated with continued exposure to dust, at least in high-incidence mines. Since their studies were confined to men who were still working they could provide no evidence on the effect of removal from such exposure. One object of the suspension of certified men from the industry, however, is to prevent progression, and we found there was a widespread belief that this object was achieved in most cases, although it was known that men in the later stages of the disease might progress after leaving the pits.

In order to study this question Dr. Alice Stewart invited a sample of men who had been certified before January, 1945, 650 in number, to attend at Cardiff for clinical and radiological examination. The sample was drawn partly from the high-incidence steam-coal area in East Glamorgan and Monmouthshire and partly from the anthracite area. It was chosen to be representative of interval since certification, of age, and of disease-stage at the time of certification. By the courtesy of Dr. Sutherland, Chief Medical Officer of the Silicosis Medical Boards, we had access to each man's x-ray film taken at the time of certification, so that we were able to assess progression by comparing in each case the first film with that which we took ourselves. We also made a full clinical examination and carried out a vital-capacity estimation, an exercise-tolerance test, sedimentation rate, haematocrit, and sputum examination in every case.

Dr. Stewart will soon be publishing a report of her findings (Stewart, 1948). I propose to confine my discussion to the nature and progression of the disease as we have observed it, particularly in the light of a more detailed analysis of the radiographs recently carried out by Dr. Idris Davies and Dr. K. J. Mann (1948). We found that progression after suspension from the industry is very common, but it is a slow process, and an interval of at least five years is usually needed to reveal it. I shall therefore consider only those who have been removed from exposure to dust for five or more years. Since all these men had been certified before the operation of the coal-miners' pneumoconiosis scheme, we did not expect to find any cases of reticulation, but the distinction between reticulation and massive fibrosis is not always easy, and in fact there were several cases which we considered to show only reticulation.

Most of these cases of reticulation remained stationary after exposure to dust, but a minority developed progressive massive fibrosis, usually in the upper

zones, and more commonly on the right than on the left. Once this appearance had developed, progression onwards to fluffy and massive shadows was the rule. An intervening stage of generalized nodulation was not seen, although a few cases of reticulation did develop nodular shadows. Cases of diffuse nodulation appeared to behave similarly to cases of reticulation, but with a rather greater tendency to advance by coalescence of nodules to the formation of massive shadows.

These changes are perhaps best illustrated by one case in which we were able to obtain intermediate radiographs between the earliest and the most recent. This man was a steam-coal collier when, in 1941, at the age of 34, an attack of pain in the chest while at work led him to apply to the Silicosis Board. His radiograph then (Plate, Fig. 4) showed reticulation in both lung fields, but in the outer half of the right upper zone there was coarser mottling. He was rejected by the Board and went into the Army. A further attack of pain in the chest led to his being x-rayed and discharged from the Army as a case of silicosis. He reapplied to the Board and was certified, his radiograph (not shown) being little changed except for a definite increase in the coarser mottling in the right upper zone. A year later a further radiograph was taken (Fig. 5). There is now an obvious fluffy shadow in the right upper zone and coarse mottling is apparent in the left first and second spaces. Three years later we saw him, and his radiograph (Fig. 6) then showed a large massive shadow in the right upper zone and a fluffy shadow in the left upper zone.

The fact that I have taken a steam-coal collier as an example is immaterial. Dr. Stewart was unable to find any difference between the disease as it appears in steam-coal and in anthracite colliers.

Pathologically, cases of reticulation and nodulation show diffuse non-collagenous coal nodulation, with or without focal emphysema (see below), although in some cases with radiological nodulation typical whorled silicotic nodules may be found. The progressive coalescent shadows are due to the presence of collagenous nodules, which may fuse to form large areas of dense coal-impregnated collagenous fibrosis. To this quite distinct condition we have applied the term "progressive massive fibrosis." It should be noted that the radiological reticulation and the underlying coal nodulation are both generalized throughout the lungs, whereas progressive massive fibrosis develops locally. This lends support to Belt and Ferris's contention that some sporadic factor other than dust is responsible for its development.

When we come to consider the frequency with which these changes are found we are in difficulties, because a considerable number of the men certified more than five years before we made our survey had died during the

TABLE V.—Radiological Progression of Certified Cases with no Dust Exposure between their Two Radiographs. (Stewart, 1948; modified by Davies and Mann, 1948)

Initial X-ray Stage	No. of Cases	X-ray Stage 5-14 Years after Leaving Underground Work			% with P.M.F. Appearing or Advancing
		Reticulation	Nodulation	Progressive Massive Fibrosis	
Reticulation	26	18	3	5	19
Nodulation ..	24	3	11	10	42
Progressive massive fibrosis ..	290	—	—	Stationary	88
				Progressed	
				36	254

interval and we could obtain no evidence concerning the progression of these fatal cases. Thus Dr. Stewart found that about 15% of the men certified with first-stage silicosis and 40% of those certified with second- and third-stage

JUNE 5, 1948

PNEUMOCONIOSIS OF COAL-MINERS

Edited
Medical Press

lucosis die within five years of certification. Presumably the fatal cases progressed more rapidly than the survivors, so that our figures based on survivors are certainly unduly favourable, especially in the more advanced cases. Table V is a simplified summary of our findings in cases with an interval of at least five years between certification and our examination, the maximum interval being 14 years. It will be seen that the vast majority of cases which at the time of leaving exposure to dust had already developed some degree of progressive massive fibrosis advanced further in the course of time, whereas the majority of cases with diffuse reticulation or nodulation remained stationary.

Radiological Progression under Dust Exposure

Having, rather to our surprise, observed this frequent progression in men who had been removed from exposure to coal dust, it was only natural that we should seek to discover in what way further exposure to dust might effect progression, especially in the earlier stages of the disease.

We were fortunate in having all the radiographs of working colliers taken by Hart and Aslett between 1938 and 1940. We found that approximately half of these men were still working underground, the remainder having left the industry for various reasons at various times. Davies and Mann have followed up a sample of these cases, all of whom continued to be exposed to dust underground for some period after their first x-ray examination. They have assessed progression in the same manner as in the certified cases by comparing the film taken by Hart and Aslett with their own findings in its early stages, so that the analysis of their findings is in its early stages, so that final quantitative results can be given, but certain preliminary conclusions may profitably be considered. (1) The interval with which we are dealing—namely, seven to nine years—is sufficient in those who have continued to work to become manifest in those who have since developed a certifiable degree of reticulation. (2) Men who have a certifiable degree of reticulation may continue at work at the coal-face even in a high-incidence mine for a period of seven years without detectable progression. (3) On the other hand, some men who had simple reticulation in 1938 and who have since developed large areas of progressive massive fibrosis.

The question is whether the development of progressive massive fibrosis is more frequent or less frequent in those men who remain at work exposed to dust than in those who are certified and leave the mines. Table VI gives a

TABLE VI.—Radiological Progression of "Certifiable" Hart and Aslett Cases. All these Cases were Exposed to Dust for at least some of the Interval Between their Two Radiographs

Initial X-ray Stage	No. of Cases	X-ray Stage 7-9 Years after First X-ray Examination			With P.M.F. Appearance or Advance
		Reticulation	Nodulation	Progressive Massive Fibrosis	
Reticulation	158	118	6	34	76
Nodulation	11	—	7	4	—
Progressive massive fibrosis	56	—	—	7	85
				Stationary	Progressed
				49	—

preliminary quantitative analysis of the progression shown by all the men in the Hart and Aslett series who had sufficient disease to have justified certification in the first x-ray film and who are thus radiologically comparable to Dr. Stewart's cases (Table V). The two series of cases, however, are not standardized for age, nor are the intervals between the

two films identical in the two series, although the interval in two groups is not very different. A comparison between the two series should therefore probably be permissible. The important distinction between the two series is that the Hart and Aslett cases continued to be exposed to dust underground in high- or medium-incidence mines for at least part of the interval between the two x-ray films, while the certified cases all left underground work after the first x-ray film. Despite this difference the proportions in the different initial x-ray categories showing advance into or within the progressive massive fibrosis category are very similar in the two series. It should be noted that these figures refer only to the number of cases showing progression in the different groups. A comparison between the rate of progression in those leaving and those remaining at work underground has yet to be made.

The results of these two radiological surveys suggest strongly, then, that the development of progressive massive fibrosis is due to some factor other than additions of further dust to the lungs.

Nature of Progressive Massive Fibrosis

What, then, is the nature of this progressive massive fibrosis? There are four sources of evidence to which it may turn for an answer to this question.

1. Clinical Evidence

This is not a very helpful source of information. The development of progressive massive fibrosis is associated with a steady increase of dyspnoea or cough and often with other consequences. The man remains fit in appearance when at rest, although breathless on exertion, until a late stage. Finally, wasting and a sallow look or oedema of the ankles suggest that the end is not far distant, but it is not easy to distinguish wasting due to the disease. Physical signs are rare, physical consequences of the disease. Physical signs are rare, and when present they are usually indistinguishable from those of chronic bronchitis.

The chief point of interest that Dr. Stewart has found lies in disturbances of the sedimentation rate. Table VII shows the

TABLE VII.—Relationship between Sedimentation Rate and Progression of Progressive Massive Fibrosis (Stewart, 1947)

Degree of Radiological Progression	Percentage of Cases with Raised and Normal Sedimentation Rates		
	Under 5 Years' Interval between Radiographs	Over 5 Years' Interval between Radiographs	
	E.S.R. Normal	E.S.R. Raised	E.S.R. Normal
Slight	58 (67)	42 (63)	85 (71)
Marked	19 (14)	81 (61)	36 (23)
	14 (18)	86 (50)	33 (65)

Figures in parentheses are the actual numbers on which percentages are based.

relationship in certified cases between an abnormal sedimentation rate, taken by the Wintrobe method, and radiological progression. In this table the type of progression has been divided into marked, slight, and no progression. In the most progressive group (those showing marked extension in less than five years) 86% have an abnormal sedimentation rate (10 mm or over in 1 hour), while in those remaining stationary for more than five years 85% have a normal sedimentation rate. In the intermediate groups (those with slower progression or those in whom progression may be starting but is not yet radiologically evident) cases with abnormal sedimentation rate appear in intermediate proportions. Here, then, we have a hint that we may be dealing with an infective process, and it is natural to turn to the bacteriologists for help.

2. Bacteriological Evidence

In classical silicosis, due to exposure to dusts containing a high proportion of free silica, progression after leaving exposure

to the dust is almost invariably due to the activity of the tubercle bacillus, although other pulmonary infections in a silicotic lung may leave excessive fibrosis in their wake (Strachan, 1948). In repeated bacteriological examinations of sputa from some 50 of our in-patients we have been unable to find any characteristic flora or any feature other than the presence of coal to distinguish these sputa from that produced by any case of chronic bronchitis, nor has there been excessive residual fibrosis in the few cases of pneumoconiosis in which we have been able to observe the development and resolution of a non-tuberculous pulmonary infection. Our attention has therefore been concentrated on the hypothesis that progressive massive fibrosis is the consequence of tuberculous infection in a lung already occupied by siliceous coal dust.

In Dr. Stewart's series 465 cases (the majority with progressive massive fibrosis) produced specimens of sputum. By the courtesy of Prof. G. S. Wilson, these were examined in Cardiff by Dr. L. Dowsett, of the Public Health Laboratory Service. There were only 17 (3.5%) in which she was able to isolate the tubercle bacillus on culture or guinea-pig inoculation. Sen (1937) found 12 out of 100 cases of pneumoconiosis in South Wales coal-miners with a positive sputum, but it is not clear how his cases were selected and how comparable they are to Dr. Stewart's. Although Dr. Stewart found that the cases with positive sputum were not usually radiologically different from the others, they did differ in that they appeared more ill.

We have observed 183 cases in various stages of the disease as in-patients. Of these, 8 (4.5%) have had a positive sputum. These positive cases had in common that they were ill men and they were all febrile at least for a few days during admission, whereas we have only occasionally observed fever in the sputum-negative cases, and then it was caused by obvious intercurrent infection. The serious significance of clinically recognizable tuberculosis has also been stressed by Gooding (1946).

Not infrequently cavitation occurs in areas of progressive massive fibrosis, an event which is usually associated with the classical history of coughing up a large amount of dense black sputum. We have had 15 cases of such cavitation under observation for several weeks as in-patients. It might have been expected that if progressive massive fibrosis is tuberculous in nature we should obtain positive sputum results from these cases. Dr. Dowsett has examined their sputum repeatedly by culture and by guinea-pig inoculation, but from only four of them (27%) could she isolate the tubercle bacillus.

Evidence from clinical bacteriology therefore suggests that these lesions are not essentially tuberculous but that they may be complicated by tuberculosis without modification of the radiological appearance, though usually with a change for the worse in the clinical picture. It is almost as if the invasion of the tubercle bacillus was but a terminal event.

Post-mortem bacteriology tells a rather different story. Dr. Enid Rogers (1946) has reported that she had evidence of tuberculosis in 75.8% of her cases of massive fibrosis at necropsy. In 1947 in a smaller series of 20 cases Dr. Sladden observed a similar proportion. However, Gooding (1946) found evidence of tuberculosis in only 26% of cases at necropsy, but he does not say how many of his cases had massive fibrosis. Dr. James, of our Unit, working under Dr. Gough's guidance in the Welsh National School of Medicine, has made a routine search for tuberculosis, by culture and guinea-pig inoculation, in 75 successive cases of massive fibrosis coming to necropsy, but has had a positive result in only 25 (30%).

3. Histological Evidence

I have already referred to Belt and Ferris's suggestion that the development of collagenous fibrosis in coal-miners' lungs is due to the operation of a "sporadic factor x," which might be tuberculosis. There was apparently the first definite suggestion of such a point of view in coal-miners' pneumoconiosis. Cummins and Sladden (1930) and later Cummins (1935) had attributed this collagenous fibrosis to the action of silica or to the action of siliceous coal dust into an area of pre-existing infective bronchitis. On the other hand, Policard (Policard *et al.*, 1936) has always maintained that collagenous fibrosis is of tuberculous origin in silicosis.

Our understanding of the pathology of coal-miners' pneumoconiosis has been considerably increased by the work of Dr. J. Gough, of the Welsh National School of Medicine, whose observations may conveniently be considered at this point. His first paper, in 1940, was concerned with the pathology of the disease in coal-trimmers, who load coal into the holds of ships. He showed that the condition was identical with that appearing in coal-miners, and that, since the trimmers work in an atmosphere heavily charged with nothing but coal dust, this dust must be regarded as fibrogenic. In agreement with Gardner (1933), Badham (1938), and Cummins (1938) he pointed out the emphysema which accompanies the disease. Gough (1947a) and J. E. Wentworth then developed a method of cutting sections of the whole lung which may be mounted on paper and viewed by the naked eye in order to make a side-by-side comparison between the pathological condition and a radiograph taken before death. This technique brought into prominence the focal nature of the lesions underlying radiological reticulation, which Gough called coal foci, thus disagreeing with Belt and Ferris's description of diffuse "dust reticulation," although he agrees that occasionally a diffuse type of coal infiltration of the lung is seen. Some of these foci are soft and impalpable, but others are hard and nodular. He also demonstrated clearly the distribution and severity of the emphysema lying in the immediate vicinity of these coal foci, for which he used the term "focal emphysema" in order to differentiate it from the large bullous type of emphysema which develops with the contraction and scarring caused by the larger areas of massive fibrosis and also from the emphysema of chronic bronchitis and asthma in non-miners. This focal emphysema, he suggested, was the most likely cause of the dyspnoea associated with reticulation and might be of fatal severity. He pointed out that this focal emphysema is not proportionate to the degree of fibrosis and is more severe in coal-miners than in cases of classical silicosis with typical collagenous nodules. A detailed account of the development of the coal focus has recently been published by Heppleston (1947), in which he attributes the development of focal emphysema to mechanical stress in the alveoli surrounding the coal nodules. Williams (1944), however, believes that the emphysema is due to stenosis of the respiratory bronchi as they pass through the coal foci.

Gough (1947b) supported the suggestion of Belt and Ferris that tuberculosis might be the agent responsible for the development of collagenous fibrosis. Indeed, he suggested it was the chief if not the sole agent. He drew a distinction between the simple coal foci and other quite distinct collagenous nodules which he called infective. Such nodules may occur discretely but are most often found in the early stages of the formation of massive fibrosis and at the periphery of such areas. They may be distinguished from the classical collagenous, whorled silicotic nodule which is found in men who have worked predominantly in rock.

Gough argues that the histology of the lesions in which tubercle bacilli can be identified and from which they can be isolated by culture is indistinguishable from the histology of lesions in which tubercle bacilli cannot be found, and that it is therefore reasonable to assign a common aetiology to all of them and to assume that the negative cases are those in which the initiating tuberculous process has died out. Moreover, there is nothing in the obviously tuberculous lesion to support the clinical suggestion that the tuberculosis is a later complication of a pre-existing non-tuberculous fibrosis. It appears as an integral part of the disease process.

4. Radiological Evidence

The radiological appearance of the earlier stages of progressive massive fibrosis is often similar to that of tuberculous infiltration. Davies and Mann (1948) have made a detailed study of these early shadows and consider that they may be divided into three groups.

1. Cases in which the appearance is typically tuberculous. The localization is apical, with a segmental distribution, often with a pleural reaction and with increased vascular markings converging downwards to the hilum. The focal shadows within the lesion are dense and do not show the granularity typical of the mottling or reticulation or non-infective coal nodulation.

2. Cases in which the appearance is *ambiguous*.—Tuberculosis is still suggested; the location is subapical, but often rather lower; there is a gradual transition from the granular mottling of the generalized dust effect to more homogeneous but still somewhat granular foci which are not of segmental distribution. There is little pleural reaction or increase of vascular shadows running to the hilum (e.g., Plate, Fig. 4, right upper zone).

3. Cases in which the appearance is *characteristic of progressive massive fibrosis*.—The shadows are subclavicular, but may lie in the lower zones. They are well separated from the periphery. At first they are composed of a coalescence of the typical granular mottling of the generalized dust lesion; later they form compact homogeneous masses (e.g., Plate, Fig. 6).

Among the Hart and Aslett cases that Davies and Mann have reviewed there were 147 that showed one or other of these types of localized shadow in addition to some degree of reticulation in either their past or their present films. Table VIII shows the types of progression they observed in these cases.

TABLE VIII.—Development and Progression of Localized Shadows in all Hart and Aslett Cases that Presented such Shadows in either the First or Second X-ray Film (Davies and Mann, 1948)

Type of Shadow in First Film	Type of Shadow in Second Film			Totals
	Tuberculous	Ambiguous	Progressive Massive Fibrosis	
Reticulation only	8	47	13	68*
Tuberculous (+ reticulation)	22†	0	1	23
Ambiguous (+ reticulation)	0	35‡	21	56

* Out of 461 cases in the whole series showing some degree of reticulation in the first film (169 of them certifiable)

† 9 of these cases had advanced; 13 had remained stationary.

‡ 28 of these cases had advanced; 7 had remained stationary.

The main points to notice in this table are: (1) When a tuberculous shadow is present in the first film it nearly always retains its characteristic appearance even in the presence of reticulation. In one case, however, a typical shadow of progressive massive fibrosis developed at the site of a typical tuberculous shadow, and this sequence of events has also been observed in a few other cases not included in this particular series. (2) The ambiguous shadows either remain ambiguous or develop into characteristic progressive massive fibrosis. (3) New shadows appearing in the second film in cases of reticulation are usually of the ambiguous type or characteristic of progressive massive fibrosis, but it is possible for a characteristic unmodified tuberculous shadow to appear in the presence of pre-existing reticulation.

Although the tuberculosis in this particular series showed a very benign type of progression we do see cases of reticulation with a superimposed rapidly progressing extensive tuberculosis.

Summing up all this evidence, then, we may say that, clinically, tuberculosis appears as an infrequent but often serious complication of the disease; pathologically, it appears to be the probable cause of most cases of progressive massive fibrosis; radiologically, when it can be identified, it usually runs an independent unmodified course, but in the presence of reticulation it may occasionally be seen to become modified and develop into typical progressive massive fibrosis.

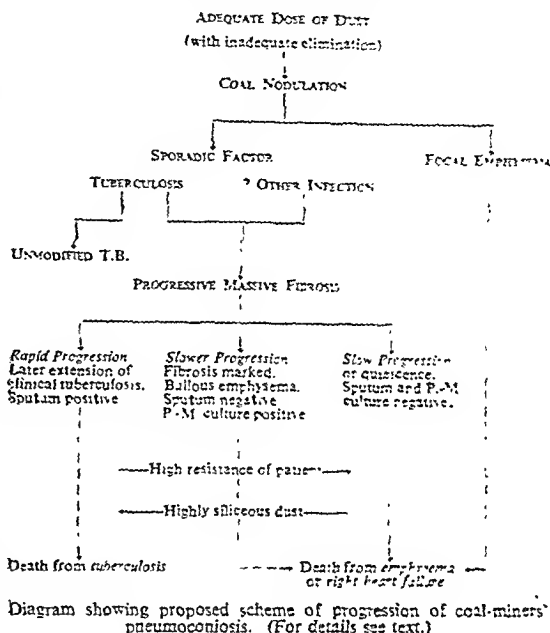

Synthesis of Present Evidence

With this conflicting evidence it is now possible to achieve any synthesis and to produce some provisional hypothesis both to interpret the observed facts and to provide a basis for action and for further investigation?

I have attempted to represent in the accompanying Diagram our present views on the nature of this disease. Any man receiving an adequate dosage of coal dust and in whom the natural means of elimination are overwhelmed may develop coal nodulation. One consequence of this in certain cases will be the development of focal emphysema. We do not know why only certain cases develop this complication. We cannot diagnose it in life, but it appears to

be uncommon except in the more elderly cases. It may become severe enough to be fatal.

Another consequence of coal nodulation is the liability to develop progressive massive fibrosis. We believe that the development of this complication may depend upon an adequate silica content of the dust and that it is due to the action of some infective agent which may be tuberculous, although tuberculosis may often pursue an independent course in the presence of reticulation. Depending perhaps upon the resistance of the patient, but also upon the silica content of the dust, progressive massive fibrosis may follow

three different types of course. (a) There may be rapid progression with the ultimate development of clinically recognizable tuberculosis and a positive sputum. Such cases die from their tuberculosis. (b) The progression may be slower, with the formation of masses of fibrous tissue which on contraction are associated with the development of bullous emphysema. Such cases are not clinically tuberculous, but from their lesions the tubercle bacillus may be cultured post mortem. They commonly die from their emphysema with right heart failure. (c) In certain cases we see very slow progression which may attain a state of quiescence. In such cases the tubercle bacillus cannot be recovered post mortem, but death is often due to the pneumoconiosis.

Our views on the nature of coal-miners' pneumoconiosis therefore lead us to talk of three diseases. There is the pure coal-dust disease, non-progressive and benign unless focal emphysema develops, when it may be fatal. In this respect it is a more serious condition than the second disease the classical non-infective silicosis of rock-workers, in which focal emphysema is much less prominent. In coal-miner these two diseases are often indistinguishably combined. Then there is a third disease process due to the interaction between some infective process, often tuberculosis, and the dust ensnared in the lung. The fundamental similarity of coal-miners' pneumoconiosis to pure silicosis is close. We believe the differences must be due, as Cummins (193) maintained, to some action of the coal dust in the lung subduing the toxic effects of tuberculosis both general

and locally, so that it is not clinically apparent, and so that the bacilli only occasionally escape from their fibrous prison to spread throughout the lung or appear in the sputum. The clinical differences between coal-miners' pneumoconiosis and silicosis are chiefly that the coal-miner with his focal emphysema and his anthraco-silico-tuberculosis is more breathless than ill and his death is like that of a chronic bronchitic with emphysema and right heart failure. He has, as Cummins has emphasized, miners' dyspnoea or miners' asthma. On the other hand, the silicotic with silico-tuberculosis is more often ill as well as dyspnoeic. He has miners' phthisis, and dies of clinically recognizable tuberculosis.

Prevention: Periodical Examinations

Having now outlined the observations that we have made on the progression and nature of this disease, the question of treatment needs consideration.

The most important preventive measure is of course dust suppression, but it may be ten years before we can properly assess the efficacy of dust suppression in reducing the incidence of the disease. For this reason some other immediate preventive measure is needed. This can be provided only by a system through which men can be removed from a dangerous environment before they have developed a significant amount of disease.

At present certification has this aim; but it is failing, for after certification the majority of men undergo serious progression. Since it is left to the initiative of the man to apply for certification, and since the early stages of the disease right up to progressive massive fibrosis may be symptomless, the present system is bound to fail. It is therefore necessary to institute a system of periodical x-ray examinations of all men exposed to coal dust, so that in every case the earliest stages in the development of the disease may be observed. In this way accurate and up-to-date evidence will gradually be accumulated of the success or failure of dust suppression. If at the same time routine periodical dust-sampling surveys are made at the men's working-places, essential information of value concerning standards of permissible dustiness will gradually be accumulated. More important still, it will be possible to advise men at the appropriate stage of the disease that they must leave a dusty working environment.

Here, however, lies the kernel of the problem. What is the appropriate stage? The final answer to this question can only be given in the light of experience gained by a system of periodical examinations in action. Since, however, it is a matter of urgency that such a system should be initiated, some provisional answer must now be given. The simplest answer would be to say that any man showing evidence of even the earliest stages of pneumoconiosis should be advised to leave the industry, but this should not be necessary if continuous medical supervision of all such cases can be assured. Moreover, large numbers of working colliers, at least in South Wales, show some early signs of pneumoconiosis in their x-ray films. To recommend all these men to leave the industry would be to cast them upon an unresponsive labour market without any training or skill outside their own profession. Further, it would mean closing a large number of the coal-mines in South Wales at a time when increased coal production is the nation's most urgent need.

Can we then provide any evidence of what may be regarded as a dangerous stage of pneumoconiosis at which men must be advised to leave a dusty working environment? The dangers which we must consider are the development of focal emphysema and of progressive massive fibrosis, for these are the chief causes of disability and

death in this disease. Unfortunately we have no evidence concerning the risk of development of focal emphysema at any particular stage of the illness, for this condition is not at present diagnosable in life. It should, however, be possible to discover at what stage of radiological abnormality a man becomes a potential candidate for the development of progressive massive fibrosis. I have attempted to get evidence on this point by reviewing all the Hart and Aslett cases which we have followed up, and of which we had a film showing progressive massive fibrosis at its earliest stage of development. There were only 28 of these cases. In all but three of them the degree of reticulation was sufficient to qualify for certification under present standards. In these three cases the intensity of the reticulation was only slightly below this standard.

The evidence at present is meagre, but, so far as it goes, it suggests that men might be ensured safety from progressive massive fibrosis if they were advised to leave a dusty working environment at a stage slightly earlier than that which at present qualifies for certification. We are now engaged upon seeking further evidence on this point.

Another factor that must be considered is the man's age. A man who does not develop a dangerous stage of reticulation until, say, the age of 55, and in whom serial x-ray films give little evidence of progression, will stand so small a chance of developing a serious degree of progressive massive fibrosis within his natural span of years that it would hardly be necessary to recommend him to leave his employment.

Next, there is the question of what a man who has already reached the dangerous stage, as I have defined it, should be advised. We have seen that there is some evidence that the development of progressive massive fibrosis may not be dependent on further exposure to dust. It is therefore questionable whether such a man would benefit by being advised to leave underground work. But we cannot deny that further accretions to the dust in the lungs may increase the liability to develop focal emphysema.

Finally, what of the man who has already developed some degree of progressive massive fibrosis? We have as yet no clear evidence on which to base an answer to this question, although we hope to obtain some evidence when we have completed our analysis of the progression shown by cases x-rayed by Hart and Aslett. The possibility that these men may develop open tuberculosis must be considered. It may be that they should be suspended in any case in the interests of their fellow workmen.

Under a system of periodical examination, then, the men to whom a change of environment should be firmly recommended are the younger men in whom serial examinations show that reticulation is approaching but has not yet reached the present certifiable level. It should be unnecessary to suspend them altogether from coal-mining, but only to offer them working places which, from continuous dust estimations and the results of periodical examinations of the men working there, are known to be safe from a risk of pneumoconiosis. The older and non-progressive cases and those who have already reached a "dangerous degree" of pneumoconiosis could, if they wished, remain at their work so long as they were free from symptoms which would necessitate their undertaking a less strenuous occupation.

The urgent necessity for the institution of an appropriate system of periodical x-ray examinations, which alone can give our coal-miners security from pneumoconiosis, cannot be over-emphasized. Such a system was recommended by the Industrial Pulmonary Diseases Committee of the Medical Research Council in 1942. It was again recommended by the Advisory Committee on Treatment and

JUNE 5, 1948

EMPHYSEMA AND PNEUMOCONIOSIS OF COAL-MINERS

rehabilitation in 1944 (Ministry of Fuel and Power, 1944). Such a system has for many years safeguarded the gold-miners at Johannesburg and Ontario and elsewhere; it is already in operation in certain silica-risk industries in this country; and it has recently been set going throughout the coal-mines in France, in which the problem of pneumoconiosis is almost as severe as it is in South Wales. The sincerity of the industry's and the Government's concern with the health of coal-miners will be judged by the speed and thoroughness with which such a system is instituted in this country.

Therapy

With regard to therapeutic as opposed to prophylactic measures, we cannot offer cure. There is no known method for reducing the fibrosis which is already present in the lungs, and at present the scarcity of sanatorium accommodation does not render practicable a proposal to treat the earlier stages of progressive massive fibrosis by prolonged bed-rest. Dr. M. C. S. Kennedy has recently joined the Unit to undertake trials of aluminium therapy, which will be started among cases of pure silicosis in the Potteries, but at present we must be content with palliative measures, which are often of value.

In the 183 cases seen as in-patients in Llandough Hospital it was found that we can help in two main ways. First, we can remove the fear of an early and distressing death under which so many of the men labour even in the earliest stages where the prognosis is good. The consequence of this fear is the grafting of a form of effort syndrome on top of the organic disability. It is too early yet to make a proper assessment of our results, but with simple, graduated general and breathing exercises we have been able to produce subjective improvement in the symptoms of many of our patients. One story may illustrate the psychological effect of such methods. It concerns a man who had been in the ward previously and had returned after six months for further investigation. He said he had been very much improved by his earlier stay in the hospital.

He asked him, "Is your breathing any better?" "No," he said. "Then is your pain in the chest any better?" "No," he said. "Then have you gained any weight?" "No," he said. "Then in what way are you better?" "Spiritually," he said. "No one but a Welsh miner would have given this answer. He illustrated what he meant by explaining that during the great frost of 1947, when the bus which took him one mile and a half to work stopped running for four weeks, he walked the whole way in the snow every day, a feat which he would not have attempted before his admission to our ward."

Secondly, we find, as many observers have found in classical silicosis, that in the dyspnoea of the later cases bronchial spasm plays an important part. Antispasmodics, specially in the form of aerosols for inhalation, may produce a dramatic improvement in exercise capacity in many cases.

Physiological Studies of Disability

I will refer briefly to one other among many lines of investigation which we are pursuing.

Dr. J. C. Gilson and Dr. P. Hugh-Jones are studying the disturbances of respiratory function in cases of pneumoconiosis by physiological methods. Apart from its intrinsic interest, this study has two important practical aspects derived from the fact that the degree of radiological abnormality in any case does not give an accurate indication of the severity of the associated respiratory disability: first, there is the need to provide some objective method of disability assessment for purposes of compensation and job selection; secondly, there is need for a means of diagnosis

in certain cases in whose x-ray films we believe that focal emphysema may have obscured the underlying coal nodulation. Two contrasting cases may illustrate the problem.

The first of these men, a steam-coal collier aged 55, is so dyspnoeic that he can only walk very slowly on the level. Although his radiograph shows some reticulation, and he has sufficient abnormality to qualify for certification, and he has been three times rejected by the Silicosis Board. In contrast to this case is the second case, that of a steam-coal collier aged 39. He works as a railway porter and finds no difficulty in carting sacks of potatoes about, but his radiograph shows massive shadows in both lung fields. This man holds our local record for the quarter-mile dash with a time of 79 seconds.

Acting on the hypothesis that emphysema, either focal or bullous, is an important factor in the causation of disability in cases of coal-miners' pneumoconiosis, Gilson and Hugh-Jones have first studied disturbances of the different divisions of the lung volume, with particular reference to the proportion of the total lung volume occupied by the residual air. This test for emphysema has hitherto proved unsatisfactory, largely because of the wide range of variation found among normal subjects, which means that it is not possible to be confident of the degree of abnormality revealed by a single estimation in any one case, but it may be of greater value in studying cases of pneumoconiosis when periodical examinations are carried out, for it will then be possible to use earlier observations on any individual case as a base-line, deviations from which may be significant even within the accepted range of normality. A report on this work will shortly be published (Gilson and Hugh-Jones, 1948). Studies of minute-volume during exercise in relation to the maximum breathing capacity are now being made. Disturbances of alveolar gas exchange are also being investigated, but preliminary results suggest that impairment of the ventilatory function of the lungs in cases of pneumoconiosis is more important than impairment of alveolar gas exchange.

Future Action

I have said that the inquiries of the Pneumoconiosis Research Unit have been largely directed towards practical sound preventive and therapeutic measures upon which it is natural, therefore, that we should look with interest for developments in the field of administrative action.

Following upon a conference held by Mr. Shinwell in Cardiff in January, 1947, a National Joint Pneumoconiosis Committee was set up in the following July, under the Chairmanship of the Parliamentary Secretary to the Ministry of Fuel and Power. On this committee the various Departments concerned with the problem of pneumoconiosis of coal-miners are represented at a high level. It has four subcommittees reporting to it on dust prevention, medical examination, treatment, and industrial rehabilitation. Members of the Pneumoconiosis Research Unit serve on these subcommittees, and a direct channel is thus provided between research and administrative planning.

The aim of this National Committee is "to prepare a co-ordinated plan for future action and to make recommendations accordingly." This is an excellent aim, but recommendations have been made in the past and they have not always been followed by action. We know that pneumoconiosis is a preventable disease and that much can be done to help those already disabled by it. The call to action is imperative.

Summary

The history of coal-miners' pneumoconiosis is briefly considered, and the investigations into the disease carried out under the Industrial Pulmonary Diseases Committee of the Medical Research Council are summarized.

The introduction of the term "reticulation" to describe the earlier radiological changes of coal-miners' pneumoconiosis is criticized.

A short account is given of dust-suppression methods. The importance of the biological approach to the design of dust-suppression methods is stressed.

The rapid increase in certification rates in recent years is described. It is suggested that in most areas it is due chiefly to the effect of the Coal-miners' Pneumoconiosis Order and to increased awareness of the disease, coupled with opportunities of alternative employment outside coal-mining, rather than to a true recent increase in disease incidence. In the steam-coal pits of East Glamorgan, however, there has been a true increase in incidence recently. There may also have been a true increase in incidence in certain other coalfields in Great Britain, but the incidence there is not likely to become as serious as in South Wales.

It is suggested that the variation in incidence of disease from pit to pit in South Wales is due chiefly to differences in the concentrations of air-borne dust underground rather than to qualitative differences in the dusts.

The post-mining employment of certified cases of pneumoconiosis is considered in the light of investigations carried out by the Pneumoconiosis Research Unit. Reasons are given for suggesting that special employment provisions are needed in addition to those already planned.

The radiological progression of certified cases who have left underground work is compared with that seen in cases continuing to work underground. Progression takes the form chiefly of the appearance of localized shadows which develop into large massive shadows. The name "progressive massive fibrosis" is applied to this condition. Its development appears to be independent of continued dust exposure.

Consideration of clinical, pathological, histological, and radiological evidence suggests that infection, perhaps tuberculous, superimposed upon a lung already occupied by dust is responsible for the development of progressive massive fibrosis.

Prevention of the disease may in the future be achieved by dust suppression. It can at present be assured only by the institution of periodical medical and x-ray examinations of all underground workers in coal-mining.

Therapy at present is only symptomatic, but much can be done by reassurance and exercise in early cases and by the use of antispasmodics in certain more advanced cases.

The physiological mechanism of breathlessness in coal-miners' pneumoconiosis is being investigated.

The prevalence of pneumoconiosis among coal-miners in Great Britain, and particularly in South Wales, calls for speedy and effective action directed to prevention and after-care.

Every member of the Pneumoconiosis Research Unit has contributed in some measure to the preparation of this paper: to them and to Dr. J. Gough, of the Welsh National School of Medicine, I wish to express my thanks for their help. I am also grateful for facts and figures supplied by the medical staff of the Silicosis Medical Boards and by officers of the Ministry of Fuel and Power and of the Ministry of Labour and National Service. The social and clinical studies that I have described have been made possible by the enthusiastic assistance given to me and my colleagues by the South Wales Miners' Federation.

I should like to thank Mr. A. V. Lambert and Mr. F. Meade for their skill in preparing the illustrations to these lectures.

"Each Regional Hospital Board should have a permanent committee consisting of members of the Board and co-opted persons, whose function would be to co-ordinate the control of tuberculosis together with that of major respiratory conditions, with the ultimate object of creating a complete service for tuberculosis and chest diseases." This is one of the recommendations that the National Association for the Prevention of Tuberculosis has recently made for the consideration of Regional Hospital Boards. The N.A.P.T. draws particular attention to certain aspects of tuberculosis that it considers neglected at present: It lists (a) the treatment of those patients with tuberculosis of more than one organ simultaneously; (b) genito-urinary infection; (c) tuberculosis in children apart from those gross cases treated in orthopaedic departments; and (d) tuberculosis in pregnant women.

intestinal fibrosis, the change is not comparable in severity to that seen in the ileum.

Uterus.—Arterioles of uterine wall show considerable narrowing as a result of intimal fibrosis.

Discussion

Although most attention has been devoted to the kidney in the study of hypertensive arteriolar lesions, the widespread nature of the change has been well recognized. Morlock (1939) studied the ratio of the size of lumen to thickness of arteriolar wall in a hypertensive and a control group and claimed to have found significant changes in a number of organs, including the gastro-intestinal tract. Foa, Foa, and Peet (1943) carried out similar measurements in muscle biopsies and compared them with those made in the arterioles of many organs from a series of post-mortem cases. They concluded that the abnormalities found in the muscle biopsies were representative of the general arteriolar changes in the rest of the body. An excellent and very complete study of hypertensive arteriolar lesions throughout the body was made by Moritz and Oldt (1937), who demonstrated that similar mild changes might be found in certain organs in non-hypertensive individuals, although severe changes were rare except in the spleen. When the changes in a hypertensive group were compared the organs most often affected were, respectively, the spleen, kidney, pancreas, adrenals, and gastro-intestinal tract. In these organs the lesions were in many cases classed as severe. It is therefore a very significant fact that two organs—namely, the kidney and the gastro-intestinal tract—should show frequent severe arteriolar lesions in hypertensive cases when in the control group showed any severe change in these organs. In contrast there were a number of cases with severe lesions of the splenic arterioles in the control group, and their appearance in hypertensive cases is thus of less significance (see Table). They furthermore noted

TABLE I
Incidence of Severe Changes (figures from Moritz and Oldt, 1937)

Organs	Severe Changes	
	Non-hypertensive Group	Hypertensive Group
Spleen	21%	55%
Kidney	0%	47%
Gastro-intestinal tract	0%	15%
Pancreas	5%	43%
Adrenals	6%	42%

that 38% of those with chronic hypertension showed superimposed acute degenerative, necrotic, and inflammatory lesions in the renal arterioles. This type of lesion was not, however, confined to the kidney, and it is interesting to note that it was found next most frequently in the gastro-intestinal tract. It is now well realized that a small number of patients with chronic hypertension, whatever the aetiology, may develop a terminal malignant hypertension, and the acute lesions described represent this condition. The fact that severe lesions are found more often in benign hypertension in the spleen, kidney, pancreas, and adrenals than in the gastro-intestinal tract is in marked contrast to the incidence in malignant hypertension. Here the gastro-intestinal arterioles are affected next in frequency to the kidney, and it clearly suggests that when severe gastro-intestinal lesions occur they are confined to cases of malignant hypertension. It should not, however, be forgotten that the renal vessels are not normally examined at necropsy, and probably have the highest incidence of all.

These observations have been amply confirmed in experimental work where the pathological picture was one of malignant hypertension. Wilson and Pickering (1938), produced hypertension in rabbits, noticed especially well-marked acute arterial lesions in the intestine. Wilson and

Byrom (1939) found in their hypertensive rats that, apart from the kidney, the most severe acute lesions were present in the mesenteric arteries, and that these lesions were as acute as to resemble those seen in human polyarteritis nodosa. This is of some interest when it is remembered that the kidney and gastro-intestinal vessels are so often affected in that disease. Pickering and Prinzmetal (1939) found acute arterial and arteriolar lesions in the gut of hypertensive rabbits and described petechial haemorrhage in that organ. This is reminiscent of Goldblatt's (1939) classical hypertensive experiments on dogs, in which he found similar petechial haemorrhages in the gastro-intestinal tract and which he attributed to rupture of a dissecting haemorrhage into the walls of severely degenerated hyalinized, or necrotic arterioles. This lesion of the arterioles he considered to be identical with that seen in malignant hypertension in man.

There are few references in the literature to gastro-intestinal arteriolar lesions giving rise to pathological changes such as ulceration and haemorrhage in man. This may be due to the fact that the disease has proved fatal before the gastro-intestinal changes have become sufficiently advanced. Klemperer and Otani (1931) described few cases of "haemorrhagic enterocolitis" in malignant hypertension, but gave very few details beyond noting that in one of these cases the lesion was confined to the jejunum and ileum. Jablons (1944) in a clinical study of gastro-intestinal symptoms in hypertension and renal disease found that most cases showed no "demonstrable macroscopic lesions" in the gastro-intestinal mucosa. He mentioned, however, that ulcerative lesions occur in malignant hypertension and are often responsible for extensive bleeding. In a series of ten cases he found ulcerative lesions of the large intestine in two. Jablons states that this ulceration may occur anywhere in the alimentary tract from the pharynx to the anus and may cause haematemesis or rectal bleeding at the outset of the disease, although it is commoner as a terminal feature. Professor Clifford Wilson (personal communication) states that he has observed vascular lesions in the bowel in many cases of malignant hypertension, sometimes leading to ulceration and in two cases to perforation and peritonitis. These observations are well in accord with the features of the present case, in which rectal bleeding developed just over two weeks before death, and in which ulceration of the small intestine with peritonitis was found at necropsy although no perforation had occurred. A clinical diagnosis was not made, probably because there was considerable sedative administration to combat the rather severe terminal hypertensive attacks.

It is therefore suggested that gastro-intestinal ulceration, haemorrhage, and perforation occur only in malignant hypertension. In this disease the arteriolar lesions are of necessity much more severe, and the gastro-intestinal vessels are involved in a greater number of cases. The recognition of such a possibility is considered to be of clinical importance, although it is realized that in a number of cases gastro-intestinal complications will occur only as a terminal event.

Summary

A case of malignant hypertension with intestinal ulceration, haemorrhage, and peritonitis is described.

The pathological lesions of the alimentary tract are accounted for by the increased vulnerability of the gut in malignant hypertension.

The possible clinical importance of recognizing such a condition is raised.

I should like to express my thanks to Dr. Geoffrey Bourne for permission to publish the case, to Prof. Geoffrey Hadfield for much valuable help and criticism, to Dr. G. S. Sansom for the photomicrographs, and to Mr. J. W. Miller for technical assistance.

SILICEOUS GRANULOMA DUE TO TALC A CAUSE OF POST-OPERATIVE PERITONEAL ADHESIONS

BY

V. ARTHUR MACKEY, M.B., Ch.B., F.R.F.P.S.G.
F.R.C.S.Ed.

AND

J. B. GIBSON, M.B., Ch.B.

From the Departments of Surgery and Pathology of the
University of Glasgow at the Western Infirmary, Glasgow.

[WITH PHOTOGRAPHIC PLATE]

Post-operative peritoneal adhesions have long excited the interest of surgeons and stimulated speculation about their pathogenesis. One is often surprised at operation by the scantiness, softness, and avascularity of intraperitoneal adhesions seen after the resolution in an unopened abdomen of a bacterial inflammation such as an appendicular abscess or a more generalized peritonitis. On the other hand, if it be necessary to reopen the abdomen after an aseptic laparotomy, adhesions may be found that are dense, vascular, and widespread. These findings suggest that laparotomy may on occasion introduce into the abdomen a substance more persistently irritant than bacteria. Observations over the past 15 years have identified one such irritant as talc—a complex magnesium silicate—the substance used almost universally in the preparation of gloves for operation. Two excellent reviews on the harmful effects of talc in the peritoneal cavity have appeared in the past year in America (Eiseman, Seelig, and Womack, 1947) and in this country (Roberts, 1947).

Within the abdomen the irritant action of talc elicits a proliferative response comparable to that found in traumatic siliceous granuloma (pseudotuberculoma silicoticum) (Shattuck, 1916; Faulds, 1935). The effects are not limited to the peritoneum, and the implantation of talc at laparotomy may be followed by granulomatous formation in the scar, by sinuses or faecal fistulae, stenosis of entero-anastomotic stomata, and, as Roberts has shown, by chronic fibrosis of the Fallopian tube with consequent sterility. The patient's history and the density of the peritoneal adhesions found at operation may suggest the diagnosis of siliceous granuloma, but the only certain proof is to find, in microscopical sections of the collagenous tissue, doubly refractile material with the appearance of talc closely related to foreign-body giant cells. The use of "polaroid" screens on the ordinary microscope is simple and usually leaves little doubt about the diagnosis, but, unless sections are examined for anisotropic material, cases may easily escape recognition and be diagnosed as tuberculosis, regional enteritis, sarcoidosis, keloid scar, or non-specific foreign-body reaction, although the situation of the granuloma may well occasion comment.

Foreign bodies such as suture material are often surrounded by giant cells and can show in varying degrees

the property of rotating the plane of polarized light, but they are unlikely to be scattered diffusely in the peritoneum, and the structure of talc as seen by polarized light is fairly characteristic (see Plate, Fig. 3). Many years after its implantation in the tissues talc has been recognized in sections prepared by routine histological methods (Roberts, 1947).

Case History

Miss B., aged 74, was admitted to the medical wards of the Western Infirmary on Oct. 3, 1947, for investigation of a severe anaemia which had developed over the past four years. She was found to be passing considerable quantities of altered blood in the stools, but intensive clinical, haematological, and radiological investigation failed to establish a source. Transfusion of 9 pints (5.1 litres) of blood over a period of a month scarcely replaced the loss, and her condition remained precarious. The decision to perform laparotomy was taken in the hope of finding the bleeding-point. She had undergone no previous abdominal operation.

First Operation.—On Nov. 26 Prof. C. F. W. Illingworth made a right paramedian incision in the upper abdomen, and his note states that wide exploration of the abdomen was carried out. A Meckel's diverticulum was found attached by its fundus immediately deep to the umbilicus. The diverticulum was not apparently the source of bleeding and so was not removed, though its tip was freed from the abdominal wall. The spleen was enlarged to perhaps twice normal size. The pre-hepatic haematological investigations having yielded no facts to contraindicate splenectomy, this was carried out and the arteries at the ends of both curvatures of the stomach were divided in the hope that the undischarged lesion might be in the upper division of the portal system. The patient recovered uneventfully from this operation, but bleeding into the alimentary tract continued. On several occasions aspiration of the stomach was carried out over long periods, but no blood was recovered. By Dec. 9 the haemoglobin level had fallen to 39, and it appeared necessary to explore the abdomen once more. In the absence of Prof. Illingworth the responsibility for this step fell on one of us (W. A. M.). The patient was prepared by transfusion of 4 pints (2.27 litres) of blood.

Second Operation.—This was performed on Dec. 9, 13 days after the first operation. There were dense adhesions of recent origin involving the stomach, omentum, the Meckel's diverticulum, and the anterior abdominal wall. The diverticulum was removed and opened but no ulceration was found. The entire small bowel contained altered blood, nowhere throughout its length could a polyp or ulcer be palpated, but accurate examination of the stomach was prevented by adhesions. The abdomen was then closed; recovery from the operation was satisfactory, and four days later the haemoglobin value was 82. Bleeding into the alimentary tract, however, continued as before, and to date is unexplained.

Pathological Report.—The specimen consists of a Meckel's diverticulum 3.5 cm. long. The peritoneum is dull and the wall thick and dense. The mucosa has a normal velvety appearance. Histological sections show zones of thickly woven collagenous connective tissue external to the muscularis and extending into it here and there for a short distance. This tissue replaces most of the subserous fat, is responsible for the increased thickness of the wall, and forms the outer surface of the diverticulum at several places (Plate, Fig. 1). Imbedded in it lie many foci of macrophages and foreign-body giant cells, arranged in some instances in the form of poorly defined follicles. These cells surround brownish crystalline doubly refractile particles of an average length of 15 μ and of a shape identical with surgical talc (Figs. 2 and 3). Similar material is seen underneath the serosa in varying concentrations in all parts of the diverticulum. The mucosa is of normal small-intestine type and no areas of gastric heterotopia are present.

Comment

There is no doubt that these lesions had their origin in the first operation, 13 days before the specimen was removed. It is comparatively rarely that the opportunity occurs to examine tissue removed from the abdomen such

a short time after laparotomy in an aseptic case, and we make this report to emphasize the speed with which dense fibrous tissues may form in response to a small quantity of talc. In the series of cases described by Eisman, Seelig, and Womack several patients complained only a few days after operation of symptoms later ascribed to talc granuloma, but histological examinations were not made in any of these until at least two months after the first operation. In our patient the reaction produced no symptoms despite its extent and intensity.

It is evident that the use of talc at operation constitutes a hazard potentially grave in its consequences for the patient. The authors of the two reviews quoted above recommend bluntly that it be abandoned. The suggested substitutes, potassium bitartrate and formolized starch, appear to be free of the irritant effect of talc, but unfortunately possess faults of their own, and the search for a completely satisfactory lubricant for gloves has not yet been successful. Until it is found we must obviously use talc with caution, make every effort to reduce the quantity to a minimum, and above all avoid depositing it in the peritoneal cavity.

Summary

The production of post-operative peritoneal adhesions by surgical talc is briefly discussed.

A case history is given of a patient whose abdomen was reopened 13 days after laparotomy. At the second operation extensive dense adhesions were found. Histological evidence is presented that these arose as a result of deposition of small amounts of talc at the time of the first operation.

We should like to thank Dr. W. R. Snodgrass and Prof. C. F. W. Illingworth for access to their records and permission to publish this case.

"TUBERCULOSIS" (COEXISTENT WITH CARCINOMA OF THE UTERUS) SHOWN TO BE SILICEOUS GRANULOMA

BY

G. HARVEY SMITH, M.D.

(From the Department of Pathology, University of St. Andrews and the Royal Infirmary, Dundee)

[WITH PHOTOGRAPHIC PLATE]

The present case was previously reported as an example of the rare coexistence of carcinoma and tuberculosis in the same organ (Smith, 1945). The diagnosis of tuberculosis was made on histological grounds without much dubiety, despite failure to demonstrate acid-fast organisms in the sections. Roberts (1947), however, has proved that granulomata occurring in the Fallopian tube, with a histological picture very closely resembling tuberculosis, may in fact be siliceous and not tuberculous: these foreign-body granulomata apparently follow the introduction of talc (surgical gloves) into the peritoneum, and in all his five cases of siliceous granuloma of the tube a previous appendicectomy had been performed and could well have been the occasion of implantation.

Each of my case in the light of Roberts's work suggests that the original diagnosis of tuberculosis is incorrect and that of siliceous granuloma rather more likely, the more so as the patient also had undergone a previous

Case History

Mrs. A., aged 44, had a "chronically inflamed appendix" removed in November, 1943; at operation the uterus was noted to be enlarged, but no signs of tuberculosis were observed. In December, 1943, there was a sudden discharge of thick yellow pus from the vagina. The gynaecologist's report was: "Mass palpable through the anterior fornix." In April, 1944, she was readmitted with vaginal bleeding and abdominal pain; at laparotomy the uterus was seen to be enlarged and white nodules were visible in the walls of both tubes at the uterine ends. The uterus and right tube were removed and sent to the laboratory. No sign of pulmonary or renal tuberculosis was detected at the time of hysterectomy; she has been well since then (46 months), and at present shows no signs of tuberculosis or malignant disease. The patient's husband, however, has recently been found to have pulmonary tuberculosis.

Pathology.—The upper part of the uterine cavity is completely occupied by a bulky friable mass of tumour tissue covering most of the posterior wall. Two small, pale, button-like nodules are present on the posterior wall, nearer the cervix. The right Fallopian tube shows a firm white nodule 1 cm. in diameter at the uterine end. Microscopically, the appearance in the uterine mass are those of an anaplastic adenocarcinoma. At the margins of the main growth, and in the two smaller nodules of tumour below, there are follicular structures, histologically tuberculous, with giant cells, areas of necrosis, and surrounding lymphocytes. The sections of the Fallopian tube show that the nodule there is not neoplasm but a further tuberculous-looking granuloma with rather more connective-tissue proliferation.

Examination of sections by polarized light revealed the presence of doubly refractive particles both in the tissues and in a few of the giant cells (Plate, Fig. 2). It also revealed a superficial collection of talc crystals with accompanying round-cell reaction immediately below the serous coat of the tube (Fig. 1). This latter lesion, although not far from the main mass of the granuloma, is highly suggestive of direct implantation of talc on the serous surface of the tube as against transport into the lumen, suggested by Roberts to explain the striking localization of the talc in his cases. It is important to note that of 70 sections of the tube only 14 showed the presence of anisotropic material. This material, as Roberts also points out, when contained within the giant cells is not always acicular in shape. Fifty-six sections of the uterine lesions have also been examined through "polaroid" screens, but no acceptable anisotropic particles have been seen.

Discussion

It is suggested that talc from the surgeon's gloves was introduced into the peritoneal cavity during the appendicectomy in November, 1943, and that this is the origin of the siliceous granuloma formed in the Fallopian tube. Although the granulomatous foci in the uterus failed to show anisotropic bodies it seems reasonable to regard them also as siliceous in nature.

The minimum period recorded by Roberts as elapsing between laparotomy and the discovery of a tubal lesion is two years; in the present case the interval was only five months. The discovery of the granuloma was, of course, incidental to the treatment of the cancer, and it is possible that the siliceous lesions would not otherwise have declared themselves for some time, if at all. The more active necrotic character of the histological changes in my case compared with those described by Roberts may well be due to the earlier stage in development of the granuloma.

The period elapsing between the implantation of siliceous material and the subsequent appearance of a superficial dermal granuloma has generally been lengthy—more so in the accident cases than in those with a lesion in a surgical scar. In most cases there appears to be a latent period, and in one traumatic case mentioned by Roberts the silica, driven mechanically under the skin as a result of a fall, lay there without provoking any noticeable reaction for 43 years.

should be noted, however, that in this type of case the irritant is a different compound of silicon from that present in talc. Even then one was hesitant to accept the present case as being siliceous, in view of the short period of five months between the appendectomy, when presumably the talc was introduced, and the subsequent discovery of a tubal granuloma. Walker (see below) has now shown that in even weeks a siliceous granuloma can produce a firm peritoneal adhesion, and Mackey and Gibson (see p. 1077) describe a florid granulomatous lesion developing within two weeks of implantation of talc. Thus in the present case, with its five-months interval, one is justified, I believe, in accepting the siliceous origin. A further argument against as proof of the siliceous origin. The fact that the tuberculous nature of the granulomata lies in the fact that there were macroscopically similar nodules in the left tube, which was left *in situ*. If these had been tuberculous or, indeed, neoplastic in nature, it is reasonable to expect that clinical evidence to that effect would have presented itself by now.

Summary

A further case of siliceous granuloma of the Fallopian tube is reported. The patient had undergone appendectomy five months prior to hysterectomy for carcinoma of uterus. Microscopy reveals the presence in the Fallopian tube of a pseudo-tuberculous granuloma with giant cells containing doubly refractive material, almost certainly surgical talc.

A granuloma similar in histological structure but without discoverable crystals is present in the uterus alongside the carcinoma.

I have pleasure in thanking Dr. Jean Herring for the clinical data, Messrs. Corkhill and Fraser for their technical assistance, and Prof. Lendrum for the photography and his help with this paper.

SILICEOUS GRANULOMA DUE TO SURGICAL TALC AS A CAUSE OF PERITONEAL ADHESION

BY

WILLIAM WALKER, M.A., M.B.

(From the Department of Pathology, University of St. Andrews and the Royal Infirmary, Dundee)

(WITH PHOTOGRAPHIC PLATE)

The following case is reported to show that a single small post-operative peritoneal adhesion can follow the use of talc.

Case Report

A woman aged 58 had a strangulated left femoral hernia for which Lotheissen's operation was performed on Dec. 24, 1947. The sac contained strangulated small bowel and omentum. The former was delivered into the peritoneum, and after application of hot packs was considered to be viable. The omentum was excised and the hernial orifice closed. The patient did well until Feb. 6, 1948, when she developed symptoms first of acute obstruction and then of perforation. On admission to hospital on Feb. 10 she was in *extremis* and died within two hours despite restorative therapy.

The necropsy findings were general peritonitis and an obstruction of the small bowel due to adhesion and kinking 5 ft. (1.5 metres) from the ileocaecal valve. The mesenteric border of the ileum was doubled back on itself for some 6 in. (15 cm.) of its length, producing a U-shaped kink, the limbs of the U being firmly adherent to each other. The proximal limb of the U was grossly distended above the obstruction, and perforation had occurred through a gangrenous portion of its wall.

There was no recurrence of the hernia. Histological investigation of the zone of adhesion reveals a fibrous fusion (see Plate, Fig. 1) in which there are giant cells containing anisotropic crystals. In the giant cell shown (Fig. 2) as photographed through partially crossed "Polaroid" screens, the mass of talc enclosed in the cell has been slightly displaced, as so often happens during the cutting of a section.

In view of the history, the impression at necropsy was that the adhesion had probably arisen in the portion of the bowel involved in the earlier hernia. However, the recent interest in talc as a cause of siliceous granuloma (Roberts, 1947) led to the microscopic examination of the adhesion. The fact that in the giant cells in this area there are doubly refractive anisotropic crystals makes it highly probable that talc introduced at the previous operation was in fact the origin of the adhesion. The lesion is slightly older than that described by Mackey and Gibson (see p. 1077), and differs in being a solitary focus.

Summary

Histological examination of a single peritoneal adhesion, observed seven weeks after a previous laparotomy, shows the reaction of siliceous granuloma with anisotropic crystals in the giant cells, probably surgical talc.

This small circumscribed lesion resulted in death.

I have pleasure in acknowledging the assistance of Prof. Lendrum and Mr. J. W. Corkhill with the photography, and of the former in the preparation of the paper.

THE LIVER IN INFECTIVE HEPATITIS*

BY

K. DAMODARAN, M.B., B.S.

Major, R.A.M.C.

(WITH PHOTOGRAPHIC PLATE)

This paper is based on the post-mortem findings on 17 cases of infective hepatitis—15 of them in Indians. The patients were admitted to four different military hospitals during 1943-7. The liver showed acute necrosis in eleven and subacute necrosis in five. The last case was under observation for hepatitis without jaundice during an epidemic of infective hepatitis in Malta.

Acute Necrosis

The onset of acute necrosis is sudden. It usually occurs within ten days after admission. In an average case of infective hepatitis the only warning, perhaps, is the presence of albumin in the urine. Mental irritability, vomiting, and stupor usher in cholaemia. Cheyne-Stokes breathing, coma, and pyrexia supervene, and the patient usually dies in three days. A marked diminution in liver dullness can be made out on percussion and the right lateral thoracic vein may be distended. There may be a significant fall in the serum proteins, especially albumin.

Case History

The patient from whom the specimen for the photomicrograph (Plate, Fig. 1) was taken was an Indian aged 22. He was admitted to hospital as an uncomplicated case of infective hepatitis in February, 1944. On the fourth day after admission he became semiconscious and irritable. The urine contained albumin, bile salts, bile pigments, and tyrosine crystals. Two days later he died. At the post-mortem examination the external appearance was that of deep jaundice. There were a

*A review of 450 cases of infective hepatitis by Damodaran and Hartfall appeared in the *British Medical Journal* dated Nov. 4, 1944 (p. 587). The reader is referred to that article for a better understanding of this paper.

few spots of petechial haemorrhage on the chest and abdomen. The peritoneum appeared normal; there was no effusion. The liver was about half the normal size and quite diffident; its surface was smooth and the capsule wrinkled on handling. The cut surface was engorged and was oozing dark-red blood. Serial sections showed no focal lesions of any type macroscopically, the changes described being entirely diffuse. The gall-bladder was small and, together with the larger biliary passages of the liver, contained a little green very viscid bile and much mucus. There were no macroscopic changes in the hepatic biliary tracts, and the mucosa of the gall-bladder and bile ducts was of normal appearance. At no point was obstruction apparent.

Microscopy of the liver showed the general picture of an acute hepatic necrosis. Except in a few scattered areas the normal architecture of the lobules was absent. Recognizable liver cells showed extreme necrosis, but many had entirely disappeared. Round-cell infiltration was particularly marked in the subcapsular areas and along the portal spaces. The biliary ducts showed no evidence of proliferation. Bile-pigment granules were scattered throughout the microscopical fields—either in the necrosed liver cells or in the macrophages. In the kidneys no changes were observed macroscopically, but microscopy revealed changes limited to the tubules, the cells of which showed marked cloudy swelling. Nothing abnormal was noticed in the other organs.

Comment

In some of these cases a pint or two of bile-stained fluid could be seen in the peritoneal cavity, and petechial haemorrhages and generalized bile-staining of the abdominal viscera were also common. The gall-bladder was never distended, nor was there any obstruction found in the bile passages. The mucous membrane of the gall-bladder appeared to be normal. It is often impossible to squeeze out bile from the gall-bladder through the bile duct and ampulla of Vater, though no obstruction is detected on opening the bile passages. The contents of the gall-bladder—a mixture of viscid bile and mucus—are so very viscid that it is impossible to squeeze them through the bile duct. This explains Eppinger's finding of obstruction of the common bile duct in the oft-quoted necropsy on a case of jaundice in which death was due to an accident.

If death took place a few days after the onset of jaundice early fibrous-tissue formation could be made out at the periphery of the lobules and the interlobular areas. Fig. 2 is the photomicrograph of a section of liver taken from a case about a fortnight after the onset of jaundice. Note the fibroblasts in the interlobular space. The tiny dark particles scattered throughout the field are pigment granules.

One of the cases of acute necrosis was receiving arsenic injections for syphilis. This patient developed jaundice after the eighth injection of N.A.B. and died on the third day after admission. Section of the liver showed the same picture as in acute necrosis, already described, but the necrosis was more advanced and extensive. In some areas the cell outlines were visible, but they were without nuclei. The portal tracts showed some infiltration with mononuclears.

Subacute Hepatic Necrosis

Subacute hepatic necrosis is a more frequent but less fatal complication. After a period of 5 to 6 months in hospital the patient often recovers. In some cases, however, the jaundice may clear up, only to relapse again and again, especially after indulgence in alcohol. These patients have a chance of slow recovery if they lead a careful life, to ban alcohol and other liver poisons.

Case History

A 35-year-old male was admitted in March, 1946, with a history of five days' constipation, dark urine, and loss of

appetite. The liver was enlarged to 2 in. (5 cm.) below the costal margin, and the spleen was palpable. The urine contained bile salts and pigments. Aldehyde and gel tests were negative. The jaundice did not clear up in spite of treatment in hospital, but slowly deepened. Ascites developed in June. The abdomen was tapped several times and large quantities of clear yellowish fluid were removed. Oedema of both legs developed later. He died on July 26. At necropsy the abdomen contained about 4 pints (2.27 litres) of clear deep yellow fluid. The spleen was firm and had increased in size, and the liver weighed 1,290 g., being markedly reduced in size; the capsule was only slightly wrinkled.

Microscopy of Liver (Figs. 4 and 5).—Section showed broad bands of fibrous tissue separating the liver lobules. The majority of the liver parenchyma cells had lost their nuclei. Some cells at the periphery of the lobules showed only normal nuclei or nuclear shadows. Many of the cells had undergone severe fatty degeneration, a number being almost completely replaced by fat globules. This change was most pronounced at the centre of the lobules. All the lobules revealed an increase of fine connective-tissue fibrils between the liver cells. The infiltration of mononuclears in the fibrous tissue is well shown in Fig. 5. There was slight proliferation of bile ducts. The fibrous tissue formed in these cases is so profuse that it is unlikely to be due to mere replacement fibrosis. It is more like a keloid growth.

Hepatitis without Jaundice

Between 1941 and 1943 I had under observation in Malta 18 cases of hepatitis without jaundice during an epidemic of infective hepatitis among the Forces. The characteristics of this group have already been described in the previous paper. The following case is mentioned because of the importance of the necropsy findings.

An N.C.O. aged 45 had a sudden onset of fever on May 16, 1942, with severe malaise, weakness, headache, and aching all over the body. His temperature rose to 105° F. (40.6° C.) on the first day, was swinging in character, and the pyrexia lasted for three days. The liver was enlarged to two fingerbreadths below the costal margin. The spleen was not palpable. On May 26 the liver was still palpable. Red cells, 4,700,000 per c.mm.; Hb, 90%; colour index, 0.95. White cells, 10,800 per c.mm. (polymorphs 44.1%, lymphocytes 48.1%, eosinophils 0.5%, basophils 0.5%, monocytes 7%).

This patient gave a history of chronic alcoholism. His age was rather too high for infective hepatitis; but the fever, enlarged liver, and marked lymphocytosis indicated a diagnosis of hepatitis without jaundice. A couple of months later he met with accidental death. At necropsy the liver was of normal size, but firmer in consistency. The surface was smooth. Microscopically, the general architecture of the lobules was maintained, but there were small collections of young vascular fibrous tissues between the lobules. The liver cells themselves showed slight fatty degeneration. The young vascular fibrous tissue must have been the result of his recent illness. The factor responsible for the hepatitis, whatever it might have been, had a destructive, degenerative effect on the liver cells and a stimulant, proliferative effect on the interlobular fibrous tissue. One is justified in assuming that he would have developed frank cirrhosis of the liver had he lived long enough.

Discussion

The study of individual cases alone gives no idea of the sequence of events, but the study of a series of cases for a long period enables one to picture what is happening in the liver. On the whole I have observed 500 cases of infective hepatitis, including 18 cases of hepatitis without jaundice, since 1941. The change in the parenchyma of the liver varies from cloudy swelling to frank necrosis of the cells with complete disappearance of the nuclei. Whatever the change is, it is not confined to a few lobules on but is diffuse throughout. The stroma, on the other hand, is stimulated to proliferation. The proliferative process leading to fibrosis is most marked on the periphery of the

the blood in infective hepatitis appears to be secondary to the disease process.

The higher incidence of infective hepatitis among officers compared with men cannot be explained on the basis of avitaminosis. It is due to the greater incidence of "jaundice-precipitating factors" among them as already discussed in the previous paper.

Summary and Conclusions

The liver changes observed in fatal cases of infective hepatitis are described in detail. The sequence of these changes is traced from acute necrosis to portal cirrhosis. If death occurs within a fortnight the findings are those of acute necrosis. After a fortnight fibrous-tissue formation becomes apparent, especially at the portal tracts. The pattern is that of portal cirrhosis. In three months' time portal cirrhosis is obvious. In eighteen months the picture is that of portal cirrhosis, both macroscopically and microscopically. Jaundice waxes and wanes according to the intensity of inflammation of the liver cells.

This sequence occurs in less than 1% of cases. In the remaining cases the liver appears to recover ultimately.

Homologous serum jaundice is not a separate entity. The difference between apparent and real incubation periods is pointed out.

My thanks are due to Colonel Chandra, Colonel Lambert, Lieutenant-Colonel Daukes, and Lieutenant-Colonel Thomson for permitting this work to be carried out in the hospitals under their command; to Captain Ross and Captain Krishnaswami for valuable help in providing slides and records; and to Mr. Dodds for the photomicrographs.

(WITH PHOTOGRAPHIC PLATE)

Tuberculous and torular meningitis give rise to very similar clinical pictures and to almost identical changes in the cerebrospinal fluid, so that the two diseases are not easily distinguishable. The clinical trials of streptomycin now being carried out make it important to differentiate between them. Levin (1937) summarized about 70 cases of torular meningitis, but the latest and most complete review of the disease is the monograph by Cox and Tolhurst (1946). Large numbers of cases have now been recorded, especially in America, Australia, and South Africa, but so far only three in Great Britain. Smith and Crawford (1930), in Harrogate, described the first case, which was diagnosed post mortem. Gelatinous swellings in the hypothalamic region and thickening of the basal and spinal meninges were found in which torula bodies were recognizable histologically. Greenfield, Martin, and Moore (1939), in London, recorded the second, which was also diagnosed post mortem. An adhesive meningitis around the basal cistern and pons was found, and torula bodies could be seen histologically in the meninges and in the perivascular spaces of the basal ganglia. Their presence was associated with granulomatous infiltration but no

caseation. Blair (1943), also in London, described the third case, which was apparently diagnosed during life by the finding of torula bodies in the cerebrospinal fluid. No details of the chemical or cytological changes were included. At necropsy the subarachnoid space over each cerebral hemisphere, together with the lateral ventricles, was filled with yellowish gelatinous material. A case has recently come to our notice in Wales.

Case Report

A clergyman aged 60 was admitted to hospital on July 24, 1947, having had severe headaches for ten weeks, with lassitude and loss of appetite. The headaches at first occurred at intervals of one or more weeks, but later became more frequent and were associated with vomiting and sometimes with blurring of vision and tinnitus in the left ear. The only abnormal sign on admission was a doubtful left extensor plantar reflex. Lumbar puncture yielded clear cerebrospinal fluid under normal pressure, with 66 lymphocytes per c.mm. and 95 mg. of protein and 684 mg. of chlorides (estimated as NaCl) per 100 ml., the Lange colloidal gold and Wassermann reactions being negative. Other investigations, including radiography of skull and chest, were negative. The headaches gradually disappeared and the patient was discharged at his own request, free from symptoms, three weeks after admission.

He was readmitted on Sept. 2, the headaches having recurred three days after he left hospital and become continuous, with daily vomiting. There was now slight mental retardation. His tendon reflexes in the right arm were brisker than those in the left, but both plantar reflexes were now flexor. There were no other significant physical signs. On Sept. 4 the cerebrospinal fluid was under increased pressure (220 mm.), but there was now only one lymphocyte per c.mm. The proteins had, however, increased to 150 mg., whilst the chlorides had fallen to 620 mg. per 100 ml. After admission his condition improved, but by Sept. 11 the headaches were again severe and stiffness of the neck and slight Kernig's sign were present. His right knee-jerk was brisker than the left, but the arm reflexes were equal. The cerebrospinal fluid pressure was now 300 mm. and the cell count less than one per c.mm. The proteins were 180 mg. and the chlorides 670 mg. per 100 ml. Ventriculography on Sept. 18 showed no abnormality. During the next month there was periodic mental confusion with drowsiness, and on Oct. 7 a left external rectus paresis and a right-sided papilloedema were noted. The cerebrospinal fluid findings on Oct. 22 were as follows: pressure, 180 mm.; cells, 25 per c.mm. (95% lymphocytes, 5% polymorphs); protein, 250 mg.; chlorides, 626 mg., and sugar 16 mg. per 100 ml. The colloidal gold curve was 3442221000. From this time onwards the patient's condition deteriorated, wasting appeared, and by Nov. 6 the right pupil was larger than the left and well-marked left hemiparesis was present. He passed gradually into coma and died on Nov. 13, six months after the onset of his symptoms. The whole illness was almost completely afebrile until the last four days.

Necropsy Findings.—Along the basilar artery and in some of the sulci over the cerebral hemispheres a few flakes of fibrinopurulent exudate were found. The pineal gland was imbedded in a yellowish gelatinous substance which filled the pial-subarachnoid space in that area. In the right side of the pons there was an area of softening about 1.5 cm. in diameter. The lateral ventricles contained slightly cloudy fluid, but were not dilated. There was an area of apparent softening beneath the ependyma of the right lateral ventricle, involving the adjacent portion of the caudate nucleus. Another area of softening involved the anterior portion of the left external capsule.

Hypostatic pneumonia was present in the lower lobes of both lungs, but there were no significant lesions in any other organ.

Histology.—Sections of the meninges showed granulomatous lesions, chiefly around the large blood vessels. The granulomata consisted of central caseation surrounded by cellular zones in which there were small round cells, polymorphs, and pale endothelial cells, some of them large and multinucleated. The lesions closely resembled tubercles, but scattered throughout

in the highly characteristic *Torula histolytica* could be seen. These are round or oval yeast-like organisms surrounded by clear zones which represent their gelatinous capsules (Plate, Fig. 1). The bodies were in some parts clustered together, and were so numerous as to exclude other cells. Their staining properties were variable, some taking a pale blue haemalum (as in Fig. 1), and with Gram stain a rather indistinct brownish colour. (We were unable to stain the spores, and no budding was seen.) The lesions in the pons and left external capsule were areas of simple softening, but a subependymal lesion in the cerebrum was a torular granuloma. It differed from the meningeal lesions in that endothelial cells, especially the giant cells, were more prominent, and there was no caseation. Occasionally a torula body could be seen in a giant cell (Fig. 2). The vessels in the surrounding brain tissue showed perivascular lymphocytic ring.

Discussion

During life this case was thought to be either a cerebral perculoma or tuberculous meningitis. This diagnosis was supported by the decreased chloride and sugar content of the cerebrospinal fluid and by the normal ventriculogram, although repeated search for tubercle bacilli was unsuccessful. As the possibility of torulosis was not considered, the torula bodies were not specifically looked for, but they may well have been present and overlooked in the cytological examination, for they are easily mistaken for red blood cells or lymphocytes. If present in the cerebrospinal fluid they can be demonstrated by mixing the centrifuged deposit with a drop of indian ink. In a smear or wet preparation they then appear as small refractile bodies surrounded by broad colourless haloes.

There were certain features which, had they been appreciated at the time, might have helped in the diagnosis of this case. The illness lasted six months, during which the patient was for variable periods quite symptom-free. Also, except for the last four days when pneumonia was developing, he was almost entirely afebrile. These facts favoured torulosis rather than tuberculous meningitis.

Our thanks are due to Dr. Idris G. Jones for permission to publish the clinical details, and also to Mr. J. P. Napper for his technical assistance with the photomicrographs.

Medical Memoranda

Large Mesenteric Cyst

Mesenteric cysts are held to be the least frequent of intra-abdominal tumours. Warfield (1932) collated 129 cases published since 1920, to which he added two of his own. He estimated that by then about 500 cases had been published since the accidental discovery of a mesenteric cyst during a dissection by the Florentine anatomist Beneveni in 1507. Since the appearance of Warfield's paper another 104 cases have been reported. Most of these are described in the South American and Scandinavian literature, however, while in the British literature only eight cases are recorded—viz., those of Steel (1933), Hastings (1934), Cross (1935), Jackman and Mayston (1936), Jewesbury (1937), Luker (1938), Riggall (1940), and Jones (1943).

CASE REPORT

A boy aged 2½ was brought up to the out-patients clinic for investigation. He had been subject to attacks of abdominal pains, especially after a heavy meal, often culminating in vomiting. These attacks would pass off gradually. The mother, from whom

this history was obtained, had noticed that the child's abdomen frequently became distended during these attacks, and that a gurgling noise was audible towards their end, even though vomiting occurred. These attacks, obviously of intermittent intestinal obstruction, had been observed about every two to five weeks, starting when the child was eight months old, and were stated to have increased in severity.

X-ray examination, undertaken shortly after the beginning of these attacks, had been negative. They were repeated, and now showed considerable dilatation of the mid-coils of the small intestine, with definite delay in the passage of barium. An extrinsic pressure defect was noted on a coil of small intestine on the right side of the abdomen, suggesting compression by a soft tissue mass. Five hours after the barium meal had been given it was still seen to be held up in the small intestine, and none had reached the terminal ileum or caecum. "There is one very persistent coil," the radiologist reported, "closely looped upon itself, which suggests that this portion of the small intestine is actually partly rotated upon its axis and thus producing obstruction." Before this report had been delivered, however, the child had to be admitted for acute small-bowel obstruction.

Laparotomy was performed under general anaesthesia. A large cyst was found in the mesentery of a loop of the lower ileum. It extended for about 10 in. (25 cm.) along the mesenteric border of the ileum from a point approximately 4 in. (10 cm.) proximal to the ileo-caecal junction. The ileum was stretched over it almost to the point of obstruction. Apart from that the mesenteric base of the affected loop was very short and showed marked thickening and scarring, suggesting that volvulus had occurred previously, probably on several occasions. Indeed, twisting of this loop around its axis was noted at the time of operation. As the size of the cyst made it impossible to shell it out without interfering with the blood supply of the overlying gut, the whole loop was removed, a side-to-side anastomosis being made. Many enlarged glands were scattered throughout the mesentery. The child made an uneventful recovery, and was discharged home on the eighth day after operation.

Microscopical examination of the cyst showed the lining to consist of ciliated columnar epithelium with squamous patches. Muscular tissue was present in the wall, and the pathologist was of the opinion that the cyst was probably of teratomatous origin.

COMMENT

Warfield, and after him Luker, divided the cysts according to their origin into the following four groups: (1) Embryocystoma (from Wolffian remnants); (2) cystic dermoid or teratoma; (3) enterocystoma (foetal intestinal diverticulum); (4) chylus cyst.

The cyst described here was in a male child. This is of especial interest, since Warfield states that the cystic dermoids and teratomata always originate from displaced ovarian tissue. According to him no mesenteric cyst of that group has ever been recorded in a male patient, although teratomatous cysts have been met with in the spermatic cord. However, the testicle on its way downwards in the retroperitoneal tissues might occasionally leave some tissue behind, as it were.

I wish to thank Mr. H. H. Stewart, under whose care the child was admitted, and who performed the operation, for permission to publish this case. Also Dr. R. J. C. Campbell, who made the x-ray examination, and Dr. C. J. Young, who supplied the microscopical report.

Recognizing that chest surgery requires a specially trained staff—medical and ancillary—with special equipment, the Society of Thoracic Surgeons has issued a "Memorandum on the Provision of a National Thoracic Service." It emphasizes that the organization must be regional and that the work must be concentrated in centres. Primary centres should be attached, if possible, to teaching hospitals, and there may be secondary and tertiary centres located conveniently in each Region. The surgery of both pulmonary tuberculosis and other chest diseases should be carried out in the same centre, but the patients should be segregated into separate wards or blocks. In London the special chest hospitals would naturally play a prominent part in the service.

Reviews

ENTOMOLOGY

Lehrbuch der Medizinischen Entomologie. By Prof. E. Martini. Third edition. (Pp. 633; 322 figures. Paper covers RM.27; stiff covers RM.29.) Jena: Verlag von Gustav Fischer. 1946.

Professor Martini's manual on medical entomology is one of the best known of the German publications on arthropods which cause and spread disease, and the present edition maintains the high standard of its predecessors. This volume contains more than 600 closely printed pages, and in so considerable a work the author might be expected to discuss in some detail most aspects of medical entomology as it relates to man. A closer examination of the text, however, shows that much of the book is on subjects which, although of great importance to the veterinary officer, protozoologist, and hygienist, are not directly the concern of the medical entomologist.

The first 120 pages are devoted to the general consideration, mainly systematic, of the *Arthropoda*, examples of which are usually, but by no means invariably, selected from creatures of medical importance. The nomenclature adopted in this section differs from that found in most modern textbooks on the subject, but the author has explained in the second and third editions his reasons for retaining this somewhat unusual classification. Pages 120-347 contain an excellent, but brief, account of "Arthropods as Parasites." The brevity referred to is due to the author's practice of including in the relatively small space available an account of insects mainly of veterinary importance. Thus, he gives as much attention to the medically unimportant genera *Gastrophilus* and *Hypoderma* as to the medically important genera *Cordylobia* and *Dermatobia*, while not only does he consider the ticks as parasites of animals as well as of man, but he includes an illustrated account of their control by dipping.

The next section of the book is entitled "Arthropods as Disease Carriers." Here again Professor Martini pursues his policy of describing the vectors of veterinary as well as of medical diseases. Furthermore, he describes the morphology and cycle of development of the parasites causing these diseases both as they appear in the arthropod vector and also during their sojourn in the vertebrate host. The result of this prodigality is that within the space of 180 pages he has packed in not only medical and veterinary entomology but a synopsis of helminthology and protozoology in so far as these subjects relate to arthropod-borne infections.

In the last section of the book he has gathered together some, but by no means all, of the more important methods for the direct control of the noxious arthropods. There is a comprehensive index and a bibliography containing almost 1,000 references. Professor Martini refers in the preface to the great difficulties under which he laboured in writing the third edition of his book, and it is significant of these difficulties, rather than a reflection on the author, that the literature quoted is nearly all from the pre-war period, and the reviewer has only noted forty-one references, of which thirty-nine are in German, to papers published after 1939. This volume is well printed and freely illustrated, indeed the production is better than most post-war publications in Britain, while the price seems most reasonable. We can recommend it as a general guide to the part played by arthropods in causing disease among men and animals.

R. M. GORDON.

PROBLEMS OF FRACTURES

The Cause and Treatment of Delayed Union in Fractures of the Long Bone. By Kenneth W. Starr, M.B., B.S., M.S., F.R.C.S., F.R.A.C.S., F.R.A.C.S. (Pp. 233; 105 figures. 42s., paper 12s.) London: Butterworth and Co. 1947.

This book is Colonel Starr's Jacksonian Prize Essay, and he has done his studies on delayed union in the fractures of the long bones during the war. The book is divided into three main parts, the first being on the morphogenesis of bone. The second deals with the histology and biochemistry and subdivides bone into primary bone, or the centre-fibred type, and secondary

or lamellar bone. It is unfortunate that he does not mention here Professor Baker's recent work on callus formation. This section of the book contains good illustrations of many sections of callus made at differing time intervals from material which became available to the author during the course of his study. He also surveys the literature on the biochemistry of bone.

The second part of the book is on the healing of fractures. The author discusses the functions of the periosteum, the blood supply, and the structure of the bone itself. He emphasizes the necessity for an adequate local blood supply in the healing of fractures. He also considers the effect of injury on living bone, and the avoidance of bone loss or destruction of the fragments. The third part of the book is a study of the aetiology and treatment of delayed union, and the author discusses chemotherapy, the closed fracture, the open fracture, the infected fracture, and the problem of plastic surgery in relation to open fractures. He stresses the value of multiple drilling of avascular bone ends in cases of delayed union; even the grafts used were subjected to this process, which was first described by Wilkey in 1913. The importance of multiple drilling is the main point of the book. No mention is made of on-lam grafting of the single or dual type. The last portion of the book contains a very useful bibliography. There are also several short but interesting historical sections. This study is scholarly one and can be recommended to all who are interested in the problems of fractures.

R. G. TAYLOR.

BIOGRAPHY OF BANTING

Sir Frederick Banting. By Lloyd Stevenson, M.D. Second edition. (Pp. 446. 25s.) London: William Heinemann Medical Books. 1947.

Dr. Stevenson gives a most interesting account of the man who was responsible for the discovery of insulin. Born on a farm in Ontario and in no way remarkable at school, Banting went to Toronto University with the intention of becoming a minister. After a year he abandoned this idea and entered as a medical student. Here again he was in no way remarkable except for his perseverance and his interest in medical matters. He qualified in 1917 and entered the Canadian Army Medical Corps in the 1914-18 war; he served in France and was awarded the Military Cross for his courage and skill under shell fire. After the war he started in practice in London, Ontario, which proved a disheartening experience: he worked at the medical school as an instructor in anatomy, physiology, and clinical surgery. It was here that he read a paper by Moses Barron on "The Relation of the Islets of Langerhans to Diabetes, with Special Reference to Cases of Pancreatic Lithiasis." He conceived the idea that it would be easy to make an extract of the islets of Langerhans if the acinar portion of the pancreas had degenerated. Dr. Stevenson's account of the trials, difficulties, and finally the success is very full and most interesting.

After insulin had been isolated his knowledge of physiology was insufficient for working out the new problems and clinical experience was inadequate for treating patients. It was not easy to work with under these conditions, and eventually turned to other fields of research. The enthusiasm in Toronto and throughout the world over the great discovery resulted in large funds being subscribed, not only for the manufacture of insulin and the care of diabetic patients, but also to provide a research institute, to which Banting was appointed director. Although he worked hard, and useful work was done in the Institute, nothing of outstanding merit was achieved in his lifetime. Many honours came to him. He was given the Nobel Prize together with Professor McLeod, was elected a Fellow of the Royal Society in 1933, and knighted in the same year. The tragedy of his death in an aeroplane accident was well described.

GEORGE GRAHAM

COMFORTING THOUGHTS

Peace of Mind. By Joshua Loth Liebman. (Pp. 206. 8s. 6d. London: William Heinemann, Ltd. 1947.

If a Rabbi who happened to be one of America's leading preachers and a Jewish metaphysician to boot were to write about Judaism and tranquillity, it would no doubt be possible for some accredited colleague to say whether his theology

REVIEWS

BOOKS RECEIVED

JUNE 5, 1948

within its prescribed limits, sound. If he were to write on dynamic psychology and peace of mind it would certainly be possible for a psychologist to say whether or not his presentation was reliable. But when a "religionist," to use his own words, "attempts to find new answers to the basic problems of human nature," "to explain what modern psychology has discovered about human beings" and "why we lose faith in life and in God," he puts himself beyond scientific criticism. He may be, as indeed Dr. Liebman believes of himself, the bearer of a new idea of God, or he may be, as the success of his book in America suggests, a not too accurate dispenser of bromides. It is not within the reviewer's province to determine these points. All he can say is that, judged by psychological standards, the book falls flat at the first hurdle. No amount of lip service to Freud—which incidentally Dr. Liebman renders freely throughout his book—can redeem the author's first and irretrievable error about repression. This he describes as "sensual evil"—that is, according to Dr. Liebman, against "sensual thoughts and impulses." It is frankly impossible to take any book on psychodynamics seriously which begins with such a common and constantly refuted error. Indeed the main interest of *Peace of Mind* is the light it sheds on the post-war tendencies of popular psychology in America. Equipped with a familiarity with psycho-analysis and an equally fleeting and uncoordinated knowledge of psychiatry and "psychosomatic" medicine, the author makes a running survey of the field of mental conflict. The reader might gather therefrom that the aims and techniques of psychiatry can strengthen the therapeutic force of religious belief and vice versa. Comforting thoughts, no doubt, for those ready to be so comforted.

EDWARD GLOVER.

Brompton Hospital Reports are always a welcome addition to the library of the chest physician, for in spite of their modest subtitle they include some of the best papers of the year on various chest conditions, medical and surgical. Volume XV (Research Department of Brompton Hospital, 10s) is no exception. It opens with a short but eloquent appreciation of the late Mr. Tudor Edwards, by whose passing the Hospital has lost a distinguished surgeon. The first paper is a modified version of his Presidential Address in 1946 to the Association for the Study of Diseases of the Chest on "Carcinoma of the Bronchus." This is a masterly survey of the main advances in knowledge over the past 25 years. No one was more competent than he to sum up these advances in pathology, diagnosis, and treatment, for he had taken a leading place in all three. The last paper is also a Presidential Address, that of Dr. Maurice Davidson to the Section of Medicine of the Royal Society of Medicine. It should be widely published, for his remarks on the present trends in medical policy are interesting and savour of Wilfred Trotter's wisdom and philosophy. In their reprint of *The Segments of the Lungs*, and Hoyle review all the investigations necessary for the mapping out of the segmental areas of both lungs, give their radiological features with ample and excellent illustration, and discuss the application of these to medical and surgical problems. The postgraduate student will find this monograph particularly useful because it sums up the advances now possible in differential diagnosis and local treatment by the judicious combination of film examination and bronchoscopy in lung abscess, bronchiectasis, and bronchial carcinoma.

The Medical Annual, edited by Sir Henry Tidy and Mr A. Rendle Short (John Wright and Sons, 25s.), provides in its 65th year its usual wealth of information, and criticism is disarmed by the publisher's apology for its late appearance. The slow tempo of book production is particularly unfortunate in a publication of this type, which undertakes to review the year's work. A random glance at 100 references reveals the effect of the publisher's difficulties, for 45 were dated 1945, 38 1946, and only one 1947. But these minor criticisms do not detract from the usefulness of the range is difficult to select specific articles for comment when the range is so wide and the standard so high, but Prof. Crew's review of social medicine, the article by Dr. Swan on rubella and congenital malformations, and that by Drs. Blodgett and Elliott Cutler on the surgical treatment of hypertension would alone make the book a profitable investment. The format and production are in accord with the traditions of John Wright, but, presumably for reasons of economy, the type face is small enough to be inconvenient to all but the most orthoptic

[Review is not precluded by notice here of books recently received]

Hallmarks of Mankind. By F. Wood Jones, D.Sc., M.B., B.S., F.R.S., F.R.C.S. (Pp. 66. 10s. 6d.) London: Baillière, Tindall, and Cox. 1948

Two lectures on the origin of man and his relation to the monkeys and apes.

Private Enterprise or Government in Medicine. By L. H. Brill, A.B., M.D., F.A.C.P. (Pp. 201. 25s.) Springfield, U.S.A.: Charles C. Thomas. 1948.

An account of private and State-controlled systems of medical service throughout the world, with special reference to the U.S.A.

Dentists Register. (Pp. 415. 18s.) London: Dental Board of the United Kingdom. 1948

Fundamentals of Human Reproduction. By E. L. Potter, M.D. (Pp. 231. 21s.) London: McGraw-Hill. 1948

Intended principally for nurses

Elements of Surgical Diagnosis. By Sir Alfred Pearce Gould, revised by Sir Cecil P. G. Wakeley, K.B.E., C.B., D.Sc., F.R.C.S., F.R.S.E. 9th ed. (Pp. 718. 15s.) London: Cassell. 1947.

A manual for students and practitioners

The Battle of the Conscience. By E. Bergler, M.D. (Pp. 246. \$3.75.) Washington: Washington Institute of Medicine. 1948

A psychiatric study of the conscience

Annata Terapeutica. Edited by M. Coppo (Pp. 672. No price.) Rome: Clinica Nuova. 1947

A review of recent therapeutics.

Experimental Physiology. By G. H. Bell, B.Sc., M.D., F.R.F.P.S.G., F.R.S.E. 4th ed. (Pp. 228. 10s. 6d.) Glasgow: John Smith. 1947

A practical manual for the medical student: More experiments are described in this edition

1947 Year Book of Endocrinology, Metabolism, and Nutrition. Edited by W. O. Thompson, M.D., and Tom D. Spies, M.D. (Pp. 575. 21s.) London: H. K. Lewis

Abstracts and notes on recent advances

Science News 7. (Pp. 127. 1s. 6d.) Penguin Books. 1948.

Includes an article on annvitamins by Prof. J. Yudkin and notes on recent scientific research by Mr. A. W. Hackett

Genetics. By H. Kalmus, Sc.D., M.D. (Pp. 171. 1s. 6d.) Pelican Books. 1948

An account for the layman

Trichomonas Vaginalis and Trichomoniasis. By R. E. Truss, M.D. (Pp. 277. 30s.) Oxford: Blackwell. 1947.

An experimental and clinical account, with a section on treatment.

Teaching Psychotherapeutic Medicine. Edited by Helen L. Wiener, Ph.D. (Pp. 464. 21s.) London: Geoffrey Cumberlege (O.U.P.). 1947

An account of a short experimental course in psychiatry taken by general physicians.

The Practice of Local Anaesthesia. By George Bankoff, M.D., D.Ch., F.R.F.P.S., F.R.C.S. 3rd ed. (Pp. 290. 30s.) London: Staples Press. 1948.

A practical guide to local analgesia, with many illustrations.

Rheology in Relation to Pharmacy and Medicine. By G. W. Scott Blair, M.A., D.Sc., F.R.I.C., F.Inst.P. (Pp. 20. 2s.) London: Pharmaceutical Press.

Two lectures on the flow of matter.

Hernia. By L. F. Watson, M.D., F.I.C.S. 3rd ed. (Pp. 72. 67s. 6d.) London: Henry Kimpton. 1948.

A textbook of the surgical treatment of hernia, with references and many illustrations.

SAFEGUARDS SECURED

The Special Representative Meeting called to consider the results of the April plebiscite and the recommendations of Council last Friday brought to an end a debate which has lasted nearly six years by passing the Council's recommendation advising the medical profession to co-operate in the National Health Service. The meeting also had before it a letter from the Ministry of Health outlining the proposed content of the Amending Bill and referring to other matters recently discussed. This letter and an account of the meeting are recorded in this week's *Supplement*. By deciding to co-operate the Representative Body brought B.M.A. policy into line with responsible public opinion, and has confirmed its reputation for sane judgment in the world of medical politics. The meeting was a great occasion for Dr. H. Guy Dain, the Chairman of Council, who dealt in a forthright and stringent manner with the criticisms levelled against the Council and expressed in a motion which was carried deploring the holding of the April plebiscite. It had been the policy of the Representative Body, Dr. Dain said, in matters of the Health Service, that the responsibility for decision should be placed upon the individual members of the profession. During the past years there had been a constantly changing position, and the Council would have been unreasonable if it had not ascertained the views of the profession in the light of the changes taking place. Division of opinion in the Council was reflected in the results of the April plebiscite. The majority of general practitioners to justify collective opposition had not been obtained. "You cannot go back on your undertaking to the people who signed both plebiscites that unless 13,000 general practitioners agreed to stay out of the Service you would not hold them to their vote against coming in. The issue of continued opposition to entrance to the Service cannot be taken up by you to-day in view of the pledge you have given."

Dr. Dain went over the points that had been gained. "What we were most afraid of was the Minister's overall powers. He has now agreed to an Amending Act which will limit his powers in creating a whole-time salaried service." The Minister had agreed that the profession shall always be consulted about Regulations, and be able to put in protests before such Regulations are made. And Dr. Dain reminded the meeting that with one exception the Ministry of Health had for thirty years always dealt with them fairly over Regulations under National Health Insurance. They had, he went on, got the right to freedom of speech and writing properly safeguarded; they had retained the position in which basic salary as a principle appeared; they had an agreement that the

Medical Practices Committee would nominate the few over-doctored areas and that in the rest of the country a practitioner could set up wherever he liked; they had been able to obtain an important modification in the midwifery service whereby any practitioner, whether on the obstetric list or not, might attend a patient on his list and be paid for it. The Minister had agreed to put into the Act that Executive Councils should elect their own chairmen. He had set up a legal committee to clarify the partnership position set out in Sections 35 and 36 of the Act and had agreed to amend the Act in accordance with the committee's findings. The Minister had agreed that if substantially more than 17,900 general practitioners join the Service the amount of the compensation (£66,000,000) will be substantially increased. He had agreed that when the Service starts on July 5 the profession can immediately raise through the Whitley Council machinery the betterment factor and the remuneration of the Spens Report. "Therefore," Dr. Dain said, "we are not bound to the present conditions as set out in the remuneration offer if we can prove to the Whitley Council that the amount is not the proper one."

They had not been able to alter the Minister's intentions about the ownership of goodwill. On that point, Dr. Dain observed, we had no support from Parliament or any political party. "What we have tried, therefore, to do," he continued, "is to see how far we can get round this point as well. We had said to ourselves: 'What is it that we own when we own goodwill?' We own the right to choose our partners and assistants, to arrange our work with one another, to say who shall succeed us, and to arrange the performance of our duties. The Minister has agreed that we may do all this so long as money does not pass which is in the nature of payment for goodwill." They had not succeeded in obtaining the right of appeal to the court but on practically every other matter, Dr. Dain said, they had succeeded in either getting rid of the difficulties that confronted them or modifying them in such a way that they would be practically non-existent. He had always been opposed to entering the Service if their freedoms were not sufficiently protected, but, in view of the modifications obtained during the last few weeks, "I believe we are now sufficiently protected to be able to say to the profession that not only can we co-operate in the further negotiations but that the safeguards we require have been effectively secured."

Dr. Dain asked whether the things which had not been given were of outstanding importance, whether they were such that would prevent them from taking a proper place in the Service. "When the position of those," he added "who wish a comprehensive service is satisfied or sufficiently satisfied, then we are left with a cleavage of opinion which began to appear at the Council meeting, between those who did not want any Service at all and those who were satisfied that the Service was such that we can enter it." They had to face that position and to bear in mind the interests of those not concerned in the Service.

The opposition to Dr. Dain's views found its most effective spokesman in Lord Horder, who considered that the April plebiscite suggested to the profession as a whole that in the minds of the Council "the so-called concessionary

of the Minister were of great importance. Lord Horder probed into the events which took place after April 7 and said that there had been doubt and confusion. "Where," he asked, "did the rot set in? Was it at the centre or the periphery, or both at the same time?" The burning question was whether the situation could be retrieved. The Council, he believed, had acted, and in the recommendations before them was proposing to act, past its mandate. The amendment to which he was speaking asked "that the *status quo ante* should be restored. It calls on the Representative Meeting to arouse itself and resume the fight." Mr. R. L. Newell, a member of Council, observed that he admired the clinical acumen of Lord Horder, but feared that his diagnosis had been warped by the acute symptoms developed in the Marylebone Division. Dr. J. A. Pridham said that the B.M.A. was the only organization outside the T.U.C. which had persuaded the Minister to its point of view. Dr. R. W. Cockshut said that though attached to the principle of retention of goodwill he would hesitate to advise the profession to go into a long and difficult fight on that question, throwing away by doing so all that they had gained; and he reminded the Meeting that the profession had agreed to a comprehensive service for 100% of the population. Dr. S. Wand and Dr. J. A. Brown pointed out that they had gained practically everything except the retention of goodwill in practice. Dr. Dain completed the rout of the opposition in a short and pungent speech. The statement that they had accepted defeat, he said, was nonsense. They had gained the greatest victory against the Government, which had been compelled to accept an Amending Act before the main Act had come into force. The Kingston-on-Thames amendment, to which Lord Horder spoke, was lost by a large majority, and finally the first recommendation of the Council advising co-operation was carried by a still larger majority judging from the show of hands. To this was added the following rider: "That the medical profession should accept service under the Act on the understanding that, in the event of an Amending Act and terms of service being unsatisfactory to the Representative Body, members serving under the Act may hand in their resignations or take such other step as is considered necessary by the Representative Body."

The important business of the day concluded, the Representative Meeting then indulged in heresy hunting. First of all, on a motion from Guildford, the Meeting was called on ask for the resignation of the Council. This was effectively met by Dr. Dain, who submitted that they had won the greatest victory of any profession against the Government, and that nothing in the Council's action justified the Guildford motion, which, on being put to the Meeting, was supported by only two or three out of the three hundred-odd representatives present. Then came a notion from Burnley complaining of "the disastrous effect on the plebiscite of the *B.M.J.* editorials of April 17 and 24," and calling upon the Representative Body for the discharge of the Editor of the *Journal*. If any defence were needed for editorial policy since April 7 it was found in full measure in the principal speech by the Chairman of Council. The leading article in the *Journal* of April 17, under the heading "Mr. Bevan's Gesture" concluded thus: "There is, therefore, everything

to be gained in responding to this gesture in a similar manner." By pressing its case in a new atmosphere those who have conducted negotiations with the Ministry of Health and the Minister have quickly reached the position in which the Chairman of Council was able to say to the Meeting: "I believe we are now sufficiently protected to be able to say to the profession that not only can we co-operate in the further negotiations but that the safeguards we require have been effectively secured." If the *Journal* has played any part in this it can receive criticism—even harsh criticism—with equanimity.

It is now up to those who support the B.M.A.'s "whole-hearted desire for a comprehensive medical service" for 100% of the population to do all they can to make the new Service as efficient as possible in circumstances which are admittedly difficult. But the difficulties, many and immense as they are, can be lessened by willing co-operation and hard work. The B.M.A. has a big task in front of it in helping to shape the new Service and in securing satisfactory terms and conditions for those who work in it. It has also an obligation to those of its members who wish to stand outside the Service, and will do what is necessary to protect their interests. The B.M.A. has come through the ordeal of six years' debate with enhanced prestige and strength, and by protracted and difficult negotiations has so modified the comprehensive Health Service advocated by all political parties that it is possible for the medical profession to take a foremost and active part in moulding it according to the highest traditions of a learned profession.

SOME DUST DISEASES OF THE LUNG

Since Koch's discovery of the tubercle bacillus tuberculosis has been the most closely studied of the diseases of the chest. It was not until about 1930, when improved technique began to have an effect, that radiological investigation became an essential part of the examination of the chest, and it was soon evident that many dusts caused abnormal shadows in x-ray films. Since then there has been much argument about the terminology of these shadows. This is probably a phase which will pass as soon as it is realized that the appearances vary much with the radiological technique. They are only shadows, and the same type of shadow may be caused by collections of inert material in the lymphatic spaces of the lung or by fibrosis in the lung itself. The essential thing to decide is the nature of the pathological process which gives rise to the shadows, the amount of disability that it causes, and the course which the condition is likely to pursue. The next great advance may well follow a study of the contaminants of the air breathed into the lung. These contaminants include not only dusts but gases; in an industrial community there must be some exposure to acid gases such as nitrous fumes, chlorine, and phosgene among others. And it is not only in an industrial community that grave disease of the lung may be caused by dust, for Fawcett¹ has shown that farmers in Cumberland may develop extensive fibrosis of the lung after handling mouldy hay, and this has also been reported recently from Switzerland² and Sweden.⁴

In this and last week's issues of the *Journal* Dr. C. M. Fletcher gives an account of the work of his research unit in South Wales. In the past three years 10,000 men from that coalfield alone have been certified as suffering from pneumoconiosis. This huge figure shows the seriousness of the problem. The survival of the nation depends on coal, and if the nation is to attract men to this industry and then keep them in it, the dust problem must be solved. It is not of course a problem confined to the coal industry alone but is one with which our other basic industries will also have to contend. The complacency with which the situation has been regarded in the past, and, judging by the lack of teaching in our medical schools, one might almost say is still regarded, is well illustrated by Fletcher's quotations from two Milroy lectures. Shufflebotham (1914) said: "At the present time in Great Britain fibrosis of the lungs among miners can be said to be practically non-existent"; and Collis (1915), "Miners' asthma, common though it used to be, has passed unobserved from our midst, and conjectures as to its character and causation are idle." Yet in 1947 men were certified in South Wales at the rate of 100 a week, and certification has risen in all the other coalfields of Great Britain, the provisional figures for 1947 showing a rise of about 1,000 in that year.

Fletcher thinks that the incidence of the disease is related to quantitative rather than qualitative differences in the dust, though he does not claim that the qualitative differences are of no importance. He has shown that there is no great difference in incidence between steam-coal areas and anthracite areas, and that while the incidence is higher in South Wales than the rest of the country the dust concentration is greater in South Wales than elsewhere. High concentration is due in the anthracite mines mainly to poor ventilation, which was especially bad during the nineteen-twenties, and in the steam-coal mines to the introduction of intensive mechanical methods of mining in the dusty coal-seams of East Glamorgan during the next decade.

In the pathological field Gough's work has been outstanding.¹ The method of cutting sections of the whole lung and mounting them on paper so that they can be viewed side by side with a radiograph taken before death is a most useful contribution to the correlation of x-ray appearances with pathological changes. These pathological changes consist of coal foci in the immediate vicinity of which are areas of severe emphysema described by Gough as "focal emphysema," and it is this focal emphysema which is the main cause of the shortness of breath from which these miners suffer. Superimposed on this focal type of disease is a progressive massive fibrosis, often necrotic in the centre and thus containing a cavity. Fletcher has concluded that so long as the disease was confined to coal nodulation and its associated focal emphysema it generally ceased to progress if the man stopped working in a high concentration of dust; but in a great many cases in which massive fibrosis had developed the condition was progressive even after the man had ceased to work underground.

It was associated with a raised sedimentation rate, and there was suggestive evidence that it might be tuberculous in origin, the "koniophthisis" of Belt and Ferris.⁶ Nevertheless, tuberculosis could often be recognized as a separate disease in addition to pneumoconiosis.

In contrast to the progressive nature of pneumoconiosis in coal-miners, Doig and McLaughlin⁷ have recently recorded the present condition of the 15 electric-arc welders who provided them with the material for their description of the condition of welders' siderosis in 1936.⁸ Of the six men in whom well-marked radiological changes had been present, two had ceased to work as welders, with the result that the iron oxide was eliminated and the abnormal shadows diminished in intensity. The process here, then, is reversible. The other four men continued to work as welders and still had abnormal shadows on x-ray examination, but after 12 years remained in good health. Two of the seven in whom radiological changes were not originally apparent now had developed abnormalities. These radiological changes, which are quite indistinguishable from the early changes of coal-miners' pneumoconiosis, are due to a dust which does not cause pulmonary fibrosis, and therefore the two conditions can be sharply contrasted.

In a recent number of *Tubercle*⁹ attention was drawn to the figures of the Registrar-General showing the great increase in carcinoma of lung during the century, which was much more marked in males than in females, and was closely correlated with the increase in cigarette smoking. These figures are of much interest in view of the work of Bradford Hill and Fanning,¹⁰ who discovered a high incidence of carcinoma of lung and skin in chemical workers handling an arsenic powder. The incidence was three times as high as in control groups in the same factory and same town. Here, then, an industrial dust gives rise to carcinoma of lung; but it is worth while recalling Thomas and Collier's observation that the arsenic content of cigarette fume may be as high as 10.5 mg. per cubic metre.¹¹ There is also a growing impression that the incidence of carcinoma of lung is high among those exposed to asbestos dust. This has been reported from France¹² and Germany,¹³ and Wyers¹⁴ has suggested that the incidence may be as high as 20% in this country. Asbestosis itself is a most disabling and rapidly progressive disease; yet since exhaust ventilation was installed in the factories in 1930 few cases have developed in persons who were not exposed to the pre-1930 conditions. The industry is therefore an excellent example of the triumph of the engineer over dust.

Holman¹⁵ has provided a historical record of the methods used by mining engineers to suppress dust up to the present time. Now that Fletcher has shown how important in the aetiology of coal-miners' pneumoconiosis is the "quantity" of dust, we can look forward with confidence to our mining engineers devising some means of suppressing the dust and thus eradicating the disease. Indeed Craw¹⁶ has already suggested that the Wether dust-allaying projector, introduced into the Cumberland

DUST DISEASES OF THE LUNG

JUNE 5, 1948

iron ore mines in 1935, has reduced the dust from many millions of particles per ml. to an average of 2,500 particles per ml., and together with strict medical control has eliminated silicosis from the mines. The insistence on medical control is important, and it is amazing that Fletcher should have to make a special plea to get established such an obvious procedure as periodical x-ray examination.

DIETETIC TREATMENT OF HEPATIC CIRRHOSIS

A form of cirrhosis closely resembling Laennec's cirrhosis in human beings can be produced in experimental animals by purely nutritional means,^{1,2} and this has led to the hope that established cirrhosis in man might prove amenable to dietary therapy. This hope is further enhanced by observation that some forms of experimentally induced cirrhosis pass through a reversible phase from which complete anatomical recovery is possible,³ but unfortunately the reversible phase cannot be distinguished histologically from the irreversible. Two factors in the diet are of outstanding importance to the liver—namely, choline and thioamino-acid cystine—and deficiency of either leads to a characteristic and specific hepatic lesion.⁴ That resulting from choline deficiency is a gradually increasing fatty infiltration, progressing to fibrosis and culminating in so-called portal cirrhosis; cystine deficiency causes a massive type of necrosis resembling acute yellow atrophy and ending either in death or in recovery with post-necrotic carrying and nodular hyperplasia. Connor⁵ has called particular attention to the former sequence of alcoholic infiltration preceding cirrhosis—in the genesis of the accumulation of fat in the liver that nutritional therapy is directed.

Owing to conflicting reports on the efficacy of such therapy in hepatic cirrhosis a study has been made in Best's laboratory in Toronto of the effects of various nutritional factors known to affect the liver upon the cirrhosis produced in rats by chronic poisoning with carbon tetrachloride. The results are published in our opening pages. Two important conclusions can be drawn from them: (1) there is a close relation between the fat content of the liver and the progression of the cirrhosis; (2) all factors that arrest or reverse the cirrhotic process are lipotropic—that is, they prevent the deposition or facilitate the removal of fat from the liver cells.

A more rational and presumably more successful use of dietary therapy might be expected from a better understanding of the mechanism by which fatty infiltration produces cirrhosis. Though there is no general agreement on this matter, strong evidence exists that the action is largely mechanical and due to impairment of the intralobular circulation. It is of especial interest that a similar mechanism has been suggested to account for the centrilobular zonal lesions that result from carbon tetrachloride poisoning.⁶ In both cases impairment of the intralobular

circulation has been demonstrated by *in vivo* microscopy and by perfusion techniques. It is the resulting malnourishment and anoxia of the centrilobular liver cells that leads to their atrophy or necrosis and consequent fibrous replacement. Since methionine is no more effective in preventing or curing cirrhosis than choline equivalent lipotropic dosage the centrilobular injury cannot be the result of thioamino-acid deficiency. It is more probable that anoxia is the most important consequence of impaired intralobular circulation, though evaluation of other essential metabolites cannot be excluded.

Recently some exceptions to the correlation between fatty infiltration and hepatic cirrhosis have been recorded. Handler and Dubin⁷ observed that severe fatty infiltration of the liver could be produced in rats on a diet containing as much as 18% of casein if 1-2% of nicotinamide was incorporated, but that cirrhosis did not appear even after six months on this diet. Hypothyroidism also leads to accumulation of fat in the liver, but despite this the subsequent development of fibrosis is retarded.⁸ The explanation of these discordant findings probably lies in the relation between metabolic activity and blood supply. A degree of vascular impairment that proves fatal at one level of metabolic activity may be quite adequate for maintenance at a lower level. Thus fatty infiltration causing intralobular circulatory insufficiency may result in centrilobular liver injury if normal thyroid activity or hyperthyroidism is present but might have no effect in association with hypothyroidism.

The fundamental change underlying the transition of reversible to irreversible cirrhosis must be one of great importance. Cameron and Karunaratne⁹ state that "we know of no histological features by which the two stages can be distinguished." Since, however, the genesis of dietary cirrhosis, and probably of carbon tetrachloride cirrhosis, is closely related to circulatory impairment, it is not inconceivable that reversibility is retained so long as the intralobular circulatory impairment is mainly the result of sinusoidal compression by distended liver cells. A stage, however, is ultimately reached at which the contraction of the fibrous tissue and the formation of regeneration nodules so distorts the vascular tree that sinusoidal compression becomes of secondary importance. At this stage the cirrhosis becomes irreversible, in the sense that neither cessation of exposure to toxic agents nor the administration of lipotropic agents can significantly affect the intralobular circulation. With carbon tetrachloride cirrhosis in rats this stage is reached after about 5 months' exposure, and the maximal period of exposure in the experiments recorded by Best was well within this period.

On the basis of these nutritional experiments on animals by Best and others a more optimistic view of the treatment of human cirrhosis is justifiable, but the indiscriminate blunderbuss therapy with proteins, amino-acids, and vitamins of the B complex is to be deprecated. Good results can be expected only if attention is given to the following points. First, the disease should still be in the reversible phase. Secondly, continued exposure to hepatotoxic agents

must be avoided. Thirdly, administration of lipotropic agents is indicated only if the cells are laden with fat, and consequently the prognosis is better in cirrhosis in those with swollen than in those with shrunken livers. Fourthly, the metabolic activity of the liver should be reduced so far as possible. Protein in large quantity, as commonly advised, probably neutralizes, by its stimulant effect on metabolism, the advantage gained by the lipotropic action of some of the constituent amino-acids. Finally, the use of antithyroid drugs might be considered worthy of trial.

DANGEROUS TALC

It is only within the last forty years that the use of sterilized rubber gloves has become a standard part of surgical operative technique. In thus reducing the risk of bacterial infection the surgeon has unwittingly introduced a new wound hazard whose harmful potentialities are only now becoming recognized. It is customary to sterilize gloves by steam, and talc powder is used to prevent them from adhering and to facilitate the insertion of the hand. The outside of the gloves is left covered with adherent talc and the tip of each finger commonly contains a somewhat larger quantity. Since talc sticking to the gloves after steam sterilization is not easily removed by rinsing in saline or water, handling the exposed tissues with such gloves introduces talc into the wound. If in the course of operation the fingertip of a glove is perforated, the talc accumulated inside may escape into the wound in dangerous amount, particularly if the puncture is unnoticed.

The effects of talc in the tissues were first recognized by Antopol¹ in 1933 and confirmed by Feinberg² and Gardner³ four years later. German⁴ described the characteristic follicular giant-cell reaction and by 1943 had collected 50 cases of talc granuloma following laparotomy. He showed that the talc particles often became widely distributed in the abdominal cavity before setting up a reaction. A new aspect of the unforeseen harm done by talc was revealed by Roberts,⁵ who showed that granulomatous lesions of the Fallopian tubes might result from the intratubal migration of talc particles introduced during a previous appendicectomy, and that sterility was the usual consequence. At a recent meeting of the Association of Clinical Pathologists Cappell and Faulds both mentioned the occurrence of tubal siliceous granuloma following diagnostic insufflation of the Fallopian tubes.

Three papers on the subject of siliceous granuloma appear in this issue of the *Journal*. Mr. Arthur Mackey and Dr. J. B. Gibson draw attention to the greater density and severity of adhesions after laparotomy as compared with those resulting from purely bacterial inflammation in the unopened abdomen, and they provide striking evidence that such adhesions may be brought about by talc within so short a period as 13 days. Dr. W. Walker describes fatal intestinal obstruction occurring only seven weeks after laparotomy and shows that the adhesions causing the fatality contained abundant talc crystals. Dr. G. Harvey Smith adds to the tubal group a case previously reported as tuberculosis (associated with carcinoma of the uterus).

There is no doubt that complications from the use of talc are much more common than is generally realized. Post-operative adhesions are not often examined microscopically, and even then their fundamental cause may escape

detection unless the sections are studied by polarized light; when the anisotropic character of the talc particles renders them conspicuous, as is shown clearly in the photomicrographs elsewhere in this issue. The newer "polarizing" screens enable the histologist to detect double-refraction with the minimum of trouble; they are so much in use in practice than Nicol prisms that they should be of constant use in every pathological laboratory in the routine examination of microscopical preparations.

These papers emphasize that talc can produce a variety of lesions, some of which may fortuitously become latent. The finding of an acceptable substitute is therefore an urgent problem. Lycopodium powder is equally harmful, and potassium bitartrate, proposed by Seelig⁶ as a substitute, is unacceptable because of its macerating effect on the hands. What is wanted is a colourless powder with the lubricant properties of talc or graphite, unaffected by steam sterilization, and giving rise to no reaction in the tissues. The problem is one first for the chemist, but, when an acceptable substitute is found, surgeons aware of the potential dangers of talc could minimize the risk by insisting that there should be no excess powder in the tips of their gloves before inserting the hands, and by removing any surplus talc from gloves before handling the exposed tissues.

PERSONNEL SELECTION

Some of the opposition to tests for the selection of candidates derives from the misconception that they are applied in a mechanical way "from the book" and that the results are right or wrong according to some predetermined scheme. As Lord Moran¹ said in the debate on entry into the Civil Service in the House of Lords on May 26, "When a callous youth who has never heard a shot fired in anger confidently claims that by his psychological tests he can tell whether an upstanding lad who has done well in the front line should or should not have a commission, naturally . . . soldiers and sailors grow impatient." It is essential that those who perform these tests should be experienced people—and more than merely experienced at setting tests. This condition is fulfilled at CISSB, where candidates for the Civil Service undergo tests of personality and intelligence for 48 hours. Some of the abundant evidence that may be obtained by such methods is described at p. 1094 of this issue. Whether what is discovered about candidates is in fact true, and whether the correct inferences are made from it, can be decided only by following up their careers for many years. The evidence from cases followed up so far indicates that the CISSB tests are helpful and not misleading, and the Foreign Office is so impressed by them that it requires all its candidates to attend the "house party"; only 25% of candidates for the administrative class of the home Service do so.

We would emphasize that the examiners applying tests for such qualities as "contact" with other people, vigour of thought, or ability to collaborate, negotiate, or win confidence must be people of great experience and mature judgment, for their opinions are often arrived at intuitively. Lord Lindsay of Birker expressed many people's fears when he said in the same debate, "I think you must restore the solid evidence of achievement in a big written examination, because all other things are so extremely subject to personal judgment." He was deploring the proposals of the Foreign Office to dispense entirely with the long written examination, and so far as medicine is concerned there is no doubt that these must remain. But it is doubtful

either the evidence of learning they provide is much more objective than the evidence relating to personality elicited by suitable tests. Two candidates know all about differential diagnosis of lobar pneumonia, yet one expresses himself lucidly, the other in a more orderly fashion; the first reveals a widely cultured mind, the second penetrating and logical one. Intuition enters into judging these qualities, yet many who disparage personality tests seem to forget this. Experienced examiners are accustomed to forming judgments with the help of intuition based on ill-designed tests. The tests need not elicit answers that can be only right or wrong; indeed, they are often not this kind. The Civil Service Commissioners are continually testing their methods in the only possible way—following up their results.

Tests of "intelligence" are useful adjuncts to tests of knowledge, and are used as such at CISSB. The candidates must have taken or be warranted able to take at least second-class honours degree. Critics of them often argue that intelligence as well as learning is revealed in long written examinations, but there can be no doubt that long examinations tend to favour the "swotter" at the expense of the man who is equally or more intelligent but who has interests outside his textbooks. The bookworm is not wanted in the Civil Service, and places for him in medicine are few. Unfortunately the scholarship system (apart from the selection of Rhodes scholars) encourages schoolmasters to train mere scholarship winners, often to the detriment of their health and character. If tests of personality and intelligence were widely adopted in selecting suitable candidates for higher education, the quality of school education as well as of the people who finally qualify for a profession or other occupation might be greatly benefited. Men are not horses to be trained for the Derby and then put to stud. The B.M.A., in its evidence to the Inter-departmental Committee on Medical Schools² attributed "some of the inefficiency which undoubtedly exists in the profession to-day" to the fact that a number of students were entering the medical schools who could pass examinations but had not the requisite aptitude, character, or staying power for a medical career. Recently the B.M.A. Medical Curriculum Committee³ has emphasized the need for experimenting with such tests, and, further, for reviewing "the suitability of the medical student to continue his course at later stages of the curriculum."

Aptitude tests can be properly designed only if a detailed job-analysis is first carried out. We understand that the Civil Service has done this. The problem for the medical profession is more complex. In the first place men with a much greater diversity of aptitude and temperament can become successful and contented doctors; in the second, the tests would be applied to a youth at the end of his schooling instead of to the semi-finished product of a university. The "house parties" at CISSB are an instructive example of how our administrators are trying to select people who will rule us intelligently and humanely.

CARBON TETRACHLORIDE POISONING

Like many other chlorinated hydrocarbons, carbon tetrachloride when inhaled in large quantities may seriously damage the liver. It also has a special affinity for the renal tubular epithelium, and, though in many of the reported cases of acute intoxication (frequently from the use of fire extinguishers) the hepatic symptoms have been most obvious, in others evidence of renal involvement has overshadowed that of disturbance of liver function. In such cases, in which oliguria or even complete anuria may be accompanied by hypertension and severe azotaemia, the

prognosis is perhaps worse than in those where hepatic injury is the more evident. It has been found both in animals and human beings that after single heavy exposures to carbon tetrachloride the liver parenchyma is capable of rapid regeneration. It appears that this process of repair can also take place in the damaged renal tubular epithelium, but less rapidly and less completely than in the liver, and unless functional restoration corresponds with anatomical the outcome is almost certain to be fatal.

Treatment in such "renal" cases must therefore be directed primarily to the kidneys, though accompanied by those measures which have been found valuable when the liver is chiefly involved. These measures, and particularly dietary treatment, are discussed at length elsewhere in this issue. In recent years peritoneal lavage and the use of the artificial kidney have been increasingly tried as a means of eliminating toxic end-products of metabolism during periods of suppressed renal function, since it has been shown that numerous substances such as urea, sulphates, phosphates, creatinine, and other waste products are filtered freely across the dialysing surface of the peritoneum.

Peritoneal dialysis is not an operation to be lightly undertaken, since it entails certain risks, not the least of which is lethal peritonitis, and its use should be restricted therefore to cases of acute renal failure associated with reversible renal changes. A recent case¹ of acute carbon tetrachloride poisoning in which the procedure was used certainly fulfilled these conditions, because oliguria had been present for nine days when peritoneal lavage was begun, and subsequent histological examination showed some degree of anatomical regeneration of the injured kidneys. To the dialysing fluid used—modified Tyrode's solution—was added the sodium salt of heparin to inhibit the formation of fibrin on the peritoneum and penicillin to inhibit bacterial growth. When peripheral oedema indicated that fluid was probably being absorbed from the peritoneal cavity into the circulation the constitution of the irrigating fluid was further modified by decreasing the amount of sodium chloride and increasing that of sodium bicarbonate, so that a closer approximation to normal blood plasma was obtained. Unfortunately, in spite of an initial subjective improvement following peritoneal lavage, the patient developed progressive symptoms of exhaustion, bronchopneumonia, and pulmonary oedema, and died ten days after admission to hospital.

The presence of new cells in the tubular epithelium showed that in this case some degree of anatomical regeneration was taking place. These cells had replaced the injured elements, but they were apparently immature and probably not capable of normal function. It was thought that if life could have been maintained for a few more days restoration of function might also have been achieved, with the prospect of complete cure. In a similar though less severe case of carbon tetrachloride poisoning with renal symptoms predominating, complete cure did take place under conservative therapy only, with a return of the blood pressure to normal and disappearance of evidence of renal disease.²

These cases emphasize the necessity of recognizing that the chief point of attack of carbon tetrachloride may be the kidneys rather than the liver, and of instituting treatment as early as possible with the object of maintaining renal function until the process of repair is established. The urgency of functional restoration must constitute the justification for such a relatively drastic measure as peritoneal dialysis.

PROBLEMS OF INTERNATIONAL TRAVEL

BY

H. S. GEAR, M.D., D.P.H., D.T.M.&H.

Cape Town

Special disease hazards result from the increasing speed of international traffic, and the gravity of these problems more than warrants a periodic examination of the situation. However, there is another aspect which is apt to be neglected in medical writings but is nevertheless important in world affairs—the effect of medical decisions on international trade and travel.

From the earliest days there has been an increasing tendency to avoid too drastic interference with traffic by quarantine practice. In his comprehensive review Stock (1945) shows that the elucidation of the causes and modes of spread of various diseases has been followed, if tardily, by an increasing international concord in reducing arbitrary medical action against traffic between countries. Stock also indicates how recent conventions have been designed to define the *maximum* measures consistent with disease control which any country may take against the people and trade crossing her borders. These modern agreements in theory, therefore, abolish unrestricted action by any country against international traffic. Nevertheless the conventions remain as compromises between modern epidemiological opinion and the demands of some authorities.

Medical Certificates

The emphasis given to some present questionable quarantine procedures has arisen paradoxically with the newer knowledge of disease spread and control. The development of immunology, for instance, has had repercussions on quarantine methods. The international traveller is increasingly being harassed by demands for certificates of vaccination against a lengthening list of diseases. The vaccination certificate has received special prestige in connexion with yellow fever, and the various processes now linked with such documents constitute a distinct obstacle to the free movement of peoples in many parts of the world.

If the yellow-fever certificate could be accepted as evidence of an absolutely reliable barrier to the spread of yellow-fever virus then no trouble would be too great to enforce its possession by all travellers. In my view the reliance placed on this document is frequently misplaced. The success of vaccination in developing a high degree of immunity in most individuals is well established. Vaccination is therefore justly accepted, but there is a considerable difference between recognizing vaccination against yellow fever as a reliable procedure and acknowledging the obligatory certificate as beyond reproach.

A yellow-fever vaccination certificate is a document, whether on an official standard form or not, which may or may not be indicative of a high level of immunity in its holder. There are both innocent and discreditable reasons for this doubt. Many certificates honestly issued are not an index of high immunity because of defects in the production and the maintenance of the viability and potency of the vaccine actually injected. Other certificates are forged. Forgeries and alterations have occurred on a considerable scale. This danger has been recognized by the wise architects of the conventions, but as yet no effective and practicable counter to the illegal and doubtful document has been evolved. The devices of standard forms and lists of approved vaccinators are but partial

remedies. Lists of approved medical officers of all the countries of the world will naturally be changing so continuously with additions, deletions, amendments, and transfers that only large bureaux can hope to compile and maintain such lists. In addition checking and deciphering signatures and designations in many languages is a laborious and difficult task unlikely to be done efficiently at most frontier posts. There is but slight similarity with immigration passport practice. A suggestion useful in theory but unlikely to appeal in practice is the assumption of quarantine control by an international authority. In the present state of the world even such a limited surrender of sovereign rights is bound to be unacceptable to most States.

That a prescribed vaccination certificate is not necessarily proof of a high level of immunity against yellow fever is only one weakness of this quarantine requirement. An equally valid criticism is that not all travellers in the particular geographical regions carry certificates. At present with air travel largely in the hands of established reputable air transport services most air travellers carry certificates. But the era of the private and charter plane is well launched, and it can be prophesied that these planes will rapidly enter inter-territorial travel in vast numbers. Little imagination is necessary to foresee the difficulty if not impossibility of applying quarantine restrictions to such craft. Land- and water-craft are also passing from endemic to non-endemic areas at speeds which bring them well within the yellow-fever danger limits. Their human complements rarely carry vaccination certificates.

The theory of the statutory yellow-fever vaccination certificate is that it implies the exclusion of carriers of virus from non-endemic areas. As the certificate is itself not always trustworthy, and as not all potentially dangerous travellers carry certificates, reliance on such a method alone is foolhardy. Even the rigid control and discipline possible in the best-organized military medical services in the recent war did not overcome these difficulties. How much less can it be expected that civilian administrations with their usually weaker control and looser organizations will achieve greater success?

The yellow-fever certificate fashion is spreading. Yellow-fever vaccination is at least highly reliable, but it is with much less assurance that complete protection can be expected in every individual vaccinated against such conditions as plague, typhus, and cholera. Thus there is smaller justification for requiring certificates against these diseases. Another unsatisfactory development is that some authorities, though their territories harbour endemic infections, demand vaccination certificates against these conditions for passing travellers. As a measure of control this seems particularly futile.

Medical Examinations

Medical examinations of passengers are not a normal routine at most quarantine posts. When applied, however, they are exceedingly drastic in their effect on both travellers and traffic. The most superficial clinical examination causes delay, annoyance, and frequently confusion, and the value of such examinations as a quarantine measure is very limited. Manifestations of infection are so protean that even in such a frank disease as smallpox, clinical examination, whether thoroughly done by experts or not, is unlikely to detect all affected persons. Further, since the dissemination of infection is a function of such varied contributors as frank, atypical, and incubating cases, subclinical infections, and carriers, it is clear that elimination of the frank and the atypical cases—the most to be expected from clinical tests—cannot stop spread.

JUNE 5, 1948

Military experience is again a valuable practical test of such procedures. One convoy embarked its troops in West Africa, where they had had the usual critical pre-embarkation medical examination. All sick soldiers were rejected and a clinically healthy population began the voyage to the Middle East. At Cape Town this convoy reported outbreaks of chicken-pox, dysentery, and meningitis. Vigorous medical action was taken, resulting in all cases and contacts being landed. Again the convoy proceeded, but merely to report further cases of chicken-pox and chicken-pox at Aden. A further weeding out at this port was also unsuccessful and fresh cases were still appearing on arrival at Suez. The many appearances of small-pox and the lesser exanthemata in troopships may also be mentioned as illustrating the futility of ordinary clinical examinations in filtering off infection. Laboratory techniques are similarly too crude or too cumbersome as yet to demonstrate invariably the presence in human beings of disease agents. Yet in times of crisis many nervous quarantine authorities give way to the hysteria of the occasion and demand, for instance, the wholesale examination of stools from every unfortunate passenger on ships suspected of harbouring cholera.

Many other examples could be given to show that, despite military control and discipline, after the isolation of frank cases and the removal of contacts infection still persisted. The less adequate control and facilities possessed by the average civilian quarantine organization give still less hope of removing infection, especially when it is realized that much human movement occurs beyond any possible official supervision.

Disease Vectors

The rat and the mosquito are the two vectors of human disease prominent in quarantine regulations. The reliance frequently placed upon frontier station methods for preventing the ingress of these potential carriers of plague, yellow fever, and malaria is often unjustifiable. The degree of attention given to vector control is inclined to vary according to the type of vessel or aircraft. Modern ocean-going liners and air-transport of the well-known lines usually conscientious in observing regulations, receive the most detailed inspection by quarantine authorities. All too often the more careless and hence more dangerous craft, such as small tramps, coastal and local sailing vessels, barges and private aeroplanes, escape the full application of vector control. Land transport—trains, motor vehicles, animal-drawn transport, and caravans—is too often completely ignored or forgotten. Thus reliance on frontier vector control alone is risky. Though fortunately not generally a major cause of obstruction or delay to international transport, arbitrary action under the relative clauses of vector control in international conventions does occur. There have been occasions when official or too nervous administrations have used the legislation to hold up ships unnecessarily for many days while searching for *Aedes aegypti* or to submit ships already in possession of satisfactory certificates and patently free of vermin to further anti-rodent measures.

Some General Criticisms

The retention of outmoded views on infection and epidemiology in spite of the spirit and principles of existing international quarantine legislation is also the source of certain general reactions on the part of many health administrations. First, the barrier motive behind vaccination certificates, frontier medical examinations, isolation of sick and contacts, and frontier vector controls has produced an all too common complacency. It is a medical

Maginot Line complex which, however fitting in the days of well-marked caravan and trade routes and stable populations, is out of place in the restless modern world. The emphasis given to quarantine measures is especially wrong when there is but spasmodic or inadequate attention given to the more important internal preventive organization. A true perspective would give precedence to the latter in rodent destruction against plague, *Aedes* control against yellow fever, louse control against typhus, and improved sanitary and health conditions within the community. Weaknesses in the barriers against the entry of infective agents which the realist must accept as almost inevitable at present will not then be so very important.

Secondly, the present legislation and practice foster unreasonable allegations concerning the origin and spread of infection which too frequently provide inter-territorial irritation. A region suffering an outbreak of one of the major communicable maladies is prone to place the blame not on its own inadequacies but on the alleged neglect or even malice of its neighbours. Communities in which a particular disease is endemic are not above seeking the explanation of recrudescences in imported infection. Such forms of recrimination are illogical, unscientific, and unhelpful in view of the demonstrable inherent weaknesses in barrier methods of quarantine practice. When the tendency to arouse international sensitivity is associated with interference with traffic, quarantine methods of doubtful medical advantage are hard to defend.

Thirdly, under existing conditions many health administrations, especially in an increasingly bureaucratic era, are often forced against their better judgment to apply the full armamentarium of quarantine. They appreciate that in the occurrence of any untoward event a scapegoat is likely to be sought. Any omission in observing the convention commandments, whether defensible on technical grounds or not, is apt then to arouse severe censure. Conversely other administrations, indifferent to lax internal conditions, conceal their deficiencies behind a façade of frontier medical activity in terms of the conventions.

Some Recommendations

In this age of speed the medical administrator would welcome above all reforms which would lessen his fear of such conditions as yellow fever, smallpox, plague, typhus, and other major aerial and vector-borne hazards. If such alterations in sanitary conventions and quarantine practice simultaneously benefit international relationship and transport they call for early adoption. As many of the prohibitions and absolute obligatory provisions of the present conventions are here claimed to be both ineffective and indirectly harmful there seems to be no justification for imposing yet more drastic frontier controls. The revision sought is rather an acceleration of the process implemented by the experts of the Office d'Hygiène Publique International, the Health Organization of the League of Nations, and U.N.R.R.A., which has been to define international control in harmony with epidemiological principles.

It is suggested that a considerable advance in the legislation is now possible which, far from reducing control over the origin and dissemination of disease, will enhance it and yet enable travel and trade to move more freely. The following principles therefore deserve prominence in the new international sanitary conventions.

(1) In view of the complex epidemiology of most major communicable diseases and of the insuperable administrative difficulties of achieving satisfactory medical control of international traffic, each State, however weak, should rely primarily on internal measures for increasing resistance rather than on efforts to prevent the entry of infection. With population movements

increasingly disturbing the "epidemic constitution" of both national and international human "herds" it is only the application of this principle which will protect the public health.

(2) Each State should recognize that there is no quarantine measure yet available which can be accepted as of anything but very limited and relative value in excluding infection from a community.

(3) It should be recognized also that no existing quarantine measures are infallible in the diagnosis of infection. Consequently allegations against other countries of "exporting" infection are fruitless.

(4) Medical advantages of any international procedure must be balanced against disadvantages imposed upon communications and trade in a world increasingly dependent upon and dominated by facilities for rapid transport.

(5) The conventions should clearly state that any application of measures in excess of those prescribed will bring repudiation by the international health authority.

If such principles are adopted it will then be questionable whether certain present absolute legal prohibitions and sanctions can be retained in the new conventions. The following may be instanced as requiring re-examination:

(a) The *obligatory* possession of immunity certificates by travellers. It is perhaps unnecessary to emphasize that the suggested deletion of the absolute legal requirement in no way diminishes the desirability of all travellers being persuaded to accept immunization. Furthermore, the change in emphasis from frontier barriers to internal protection will imply the need for large-scale programmes of vaccination for population at special risk.

(b) The forcible detention or delay of ships, aircraft, and land-craft for medical examination of the crew, passengers, freight, or accommodation.

(c) The examination, detention, or removal of contacts or suspects with consequent delay of craft.

These last two sanctions have been abused so often that their reduction, especially in the face of their doubtful usefulness, is overdue. It is not the purpose of this paper to review the other features of international sanitary legislation and practice. The establishment of epidemiological bureaux, the exchange of epidemiological and medical intelligence, the investigation of health problems, the programme of health and medical education, the improvement of the conditions of ships, aircraft, sea- and air-ports, and many other excellent results of the sound construction of the conventions are fully acknowledged. It is also not necessary to refer to the vast prospect of mutual co-operation and regional co-ordination now opening with the appearance of the new World Health Organization.

The removal or reduction of obligations and practices in the conventions which are scientifically unsound or administratively impossible should enhance the value and status of all international medical legislation and agreement. There should then follow a better approach on the part of health administrations to both their internal and external responsibilities, which in turn must lead to improved health and well-being for their communities. Such a reorientation in the sphere of international medicine will be a direct contribution to fuller and more harmonious international relations.

Summary

Medical interference in world traffic still exists in spite of the advance in international sanitary legislation. This partly arises out of the increasing demand for travellers to hold vaccination certificates and to submit to medical examinations, and partly to medical interference with shipping and aircraft. Arguments are put forward suggesting that such restrictive vaccination practice is of limited value and is dangerous to the public health and to the sense of security. It cannot guarantee exclusion of infection and is no protection against the recrudescence of disease. It leads to the neglect of more valuable

internal measures for improving medical organization and sanitary conditions. It also contributes to international friction.

There is thus a need for the international sanitary convention now being revised to reduce "police" measures, to emphasize national self-reliance and responsibility, and to clear the way for better national health services and world transport less shackled with medical restrictions.

Stock, P. G. (1945). *Proc. R. Soc. Med.*, 7, 17.

SELECTION OF CIVIL SERVANTS

[FROM A CORRESPONDENT]

The Civil Service has acquired the unfortunate (and perhaps unjustifiable) reputation of recruiting men of first-class intellectual ability but of indifferent personality, or, if it succeeds in attracting men endowed with humanity, vigour, decisiveness, and sound judgment, of so restricting the development of these qualities that their possessors in time become timid, brittle, hermetic. Many people may have been surprised, therefore, when Sir Percival Waterfield, the First Civil Service Commissioner, recently defined the qualities required in the administrative class of the home Civil Service or the senior branch of the Foreign Service as "brains, personality, effectiveness, judgment, and integrity, the whole blended into a sane and balanced individual by the process of education."

The old opinion of our administrators was perhaps not wholly a myth; the administrative class of the Service was formerly more remote from professional, trade union, and business interests than it is to-day. Its staff must now sometimes mix in the rough world outside Whitehall, and the Civil Service Commissioners are therefore trying to recruit a rather different type of man or woman and to prevent the entry of those who, though highly intelligent, have not the capacity for personal negotiation and humane administration. They have now the additional problems of obtaining staff for vacancies that occurred during the war but were not filled, and of selecting men and women who were not then free to enter but who can now apply—people whose ages range up to 32. One method that they are using is the 48-hour "house party," where personnel selection tests are applied. The Civil Service Selection Board—CISSB for short—which was set up in August, 1945, holds these examinations at a delightful country house at Stoke d'Abernon, in Surrey. As an observer I recently joined a "party" and watched the candidates being put through their paces.

At present all vacancies in the Foreign Service and 25% of those in the administrative class of the home Civil Service are filled by candidates who have been through CISSB. They must have obtained, or be certified by their tutors as able to obtain, at least a second-class honours degree, and they must have passed a qualifying written examination on general topics, where also they must show that they can express themselves clearly in good English. About 40% of the candidates fail at this stage. CISSB does not pass or fail the other 60%; it elicits evidence and makes recommendations; a Final Selection Board accepts or rejects the candidates.

The CISSB staff is drawn from the Civil Service, the universities, the Forces, business, and elsewhere, and includes a number of trained psychologists. In addition to this diversity of experience they are helped by confidential reports on each candidate from his school, university, employers, and commanding officer, and by the candidate's personal references.

Mental Tests

When I arrived the candidates had already been given numbers, by which they are known throughout the test, been sorted into three groups of six to eight (seven is considered the most suitable number), and were drinking tea copiously but in a subdued manner to refresh themselves after two hours' mental testing during the afternoon. These tests are of two kinds—cognitive and projection. The former are "intelligence" tests specially designed for this type of sample of the population and are performed at high speed against the clock; only

the most able succeed in completing them. The first, a general information test, consists of a long list of names of notable men and women in all walks of life which any diligent newspaper reader with a retentive memory ought to know; against this list is a column of descriptions, arrayed in a quite different order, by which they can be identified; the candidate is required in a third column to mark the description that fits the name. On the whole this test is not difficult for the man who has a practical and varied interest in public affairs.

Their perceptual efficiency is then tested by means of simple line diagrams. A standard set is shown, and then 200 fragments of one or other of those in the sample must be identified as being detached from one of the complete diagrams. People with mathematical or mechanical ability tend to excel in this test. Two word tests follow. In the first a list of words lies beside a list of half words. Each half word has to be completed so that it means much the same as its mate—e.g., lucky, *fortunate*. The second is two lists of words with a blank column between them. Into the space between each pair of words the candidate must insert a word that rhymes with the first and means the second—e.g., lucky, *plucky*, courageous. Facility in the use of language is naturally a help in performing these tests.

Finally a number of paragraphs, some of considerable complexity, extracted from official documents are shown to the candidate together with a list of inferences that may or may not be truly made from them. He is required to mark the correct inferences. This test sets just those problems that will often beset the Civil Servant, and, though they struck me as formidably dull, several candidates whom I subsequently asked about them all replied that their interest had been aroused.

The projection tests give some insight into a candidate's personality. A number of photographs of mildly emotive human situations are thrown on to a screen; they depict perhaps a man parting from a woman on the highway, children quarrelling, and so on; and the candidate is allowed 2½ minutes to write a few sentences commenting on the scene. The screen is then shown blank, and the candidate must describe an imagined picture and comment on it. A matter-of-fact or highly imaginative interpretation, a sensitive, indifferent, or hostile attitude to human relationships, tenderness, harshness, aggression, and cynicism—all these may appear in the responses and suggest the presence or lack of certain qualities in the candidate.

A word association test elicits information of a similar kind. Thirty simple words such as tree, snake, father, station, class are presented successively for 15 seconds and the candidate writes his response in a short sentence or phrase. The associations aroused may be consistently platitudinous, unusual, negativistic, or a well-proportioned mixture. A few clichés and cracker mottoes from potential Civil Servants may not be a bad thing, though they should be leavened by some homely and personal associations; but many bizarre responses might indicate a cast of mind that would be more at home, perhaps, in Parliament or journalism.

Each candidate also writes a short account of himself as though, first, by an appreciative friend, and, secondly, by a discerning critic. Such comments reveal the man with good or poor insight into his mind, the capacity to criticize himself justly or unjustly, the narrow judgment of a prig, the conscience of a pickpocket or a Puritan, the man "assured of certain certainties."

Group Tests

After tea I was allotted to one of the groups to watch their first group test—an informal discussion for twenty minutes on "The Role of the United States in World Affairs." Three assessors test each group—a chairman, an observer, and a psychologist. One of them announces the title of the discussion, but they do not take part in it. We sat around in easy chairs. The sort of qualities revealed in these discussions are ability to discern quickly the point of an argument, to stick to the point, to argue rationally, to develop the discussion rather than jump continually to another aspect of it, to use common sense or academic learning, to summarize quickly, to form an independent judgment, to show an imaginative interest in the topic, and so on. Some candidates make boring speeches instead of discussing; some speak too briefly, some too long; somebody may

try to dominate the group, others may submit too easily. The practical man may stick to concrete examples, the academic talk from a book, the impatient interrupt too often, the honest man show his integrity. Some tend always to agree or disagree. (In this discussion nearly all agreed with the others: "I agree with you, but . . ." was a favourite phrase of entry; they were still rather shy and thus tried to shelter in the group.) Some candidates contribute their opinions in the form of questions—"Don't you think that . . ."—rather than affirm their beliefs; some state their beliefs without supporting them rationally; or a candidate may sum up and define without contributing fresh ideas.

This test—so simple in form—is remarkably revealing, and as soon as it is finished the assessors meet to discuss the candidates' performance and allot marks. The qualities that they consider include vigour and clarity of expression, prolixity or conciseness, methodical presentation of facts, practical outlook, sophistication, adaptability, the candidates' convictions, their insight into human problems, whether they are aggressive, adaptable, sensible, alert, whether they encourage the group to collaborate, whether, indeed, they talk sense.

In the evening the candidates are introduced to "Fantasy Island," where the population is mixed, the administration and amenities primitive, and well-meaning philanthropists want to set things right. They study the data and write a short paper on its problems.

The next morning each group holds "committee discussions" on the problems of Fantasy Island, first on the paper previously written, when the chairman is elected by the candidates, and then on short questions set by the assessors, when the candidates take the chair in turn. The chairman is expected to show ability in presenting the problem clearly to the committee, working through the agenda in the time allotted (about 20 minutes), keeping his colleagues to the point, being responsive to their opinions rather than forcing his own on them, and in lucidly summing up the committee's agreed decisions. The other committee members show whether they talk sensibly, persuasively, naively, solemnly, and so on.

In the afternoon each candidate speaks to a small audience for 10 minutes on a subject chosen by the assessors from a list of several that he has previously handed in, twenty minutes being allowed for preparation. He also states the kind of audience he imagines he is addressing, such as a trade union meeting, a university discussion group, a gathering of a women's institute. When candidates are not speaking they are either having private interviews with the psychologist attached to their group or forming part of the audience.

During the day the assessors of all three groups meet and rearrange the candidates into three fresh groups. Each of these "mixed groups" holds a group discussion in the evening of the same day or morning of the third. The subjects are chosen by the assessors and are more abstract than that discussed on the first day; to some extent they vary according to the type of candidates in each group. I watched them discuss "Criteria for Democracy," "The Conflict between Private Conviction and Public Duty," and "Individual and Community." By mixing the groups for these discussions the assessors gain a wider background against which to set the candidates in their original group.

Finally, each candidate ranks on a form his group companions in the order in which he thinks they would be most suitable (1) as a Civil Servant, and (2) as a holiday companion.

The assessors now meet to sum up the candidates' abilities and qualities at every stage and all have had private interviews with them. They pay great attention to the candidates' academic and personal testimonials, and have acquired considerable skill in interpreting the usually laudatory phrases of such documents. They take into consideration age, war service or other work, and academic distinction, and relate these to what they have learned of the candidates at the "party." His records will often show whether a candidate is hard-working, enjoys social activity, has wide interests, or fits from the common man's another. Does the candidate appreciate the common man's point of view? Is he good-hearted, vigorous, buoyant, impulsive? Can he make contact with an audience, negotiate well? The assessors consider these and many other points and finally allot the marks.

Value of CISSB

Is CISSB a success? The Foreign Office thinks so and requires all its candidates to pass through it. The home Service is more cautious; most of its candidates still enter by examination and final interview. They defend their opinion on the grounds that a certain type of candidate—perhaps the dour Scot or the “prickly” Englishman—might create a very unfavourable impression at the “house party” and its report mislead the Final Selection Board. Only a careful follow-up of the results can tell, and CISSB is carrying this out. So far 150 candidates have been reported on after one year, and a report on every candidate after six months is received. Statistical analyses are also being made to find out what each part of the CISSB procedure contributes to the final result and what features of the candidates’ background are most closely correlated with success or failure at the “party.”

Apart from the problem of whether CISSB succeeds in discovering those candidates with the qualities required by the Civil Service Commissioners is the much wider one of whether the men and women with these qualities will be contented in the Civil Service. Unless the follow-up investigations are carried out with this distinction in mind they may lead to inaccurate results, for the men may prove to be failures in the Service because their personality, effectiveness, and judgment—correctly discerned by CISSB—are frustrated too often. Sir Percival Waterfield, who found time to visit CISSB while I was there, emphasized that the Service to-day welcomes such men and finds the right work for them. On the other hand I have heard men with some experience of the Service in a humbler capacity dissent from that view, or maintain that it is only the senior men who are able to give full rein to the vigour, enthusiasm, and interest in human affairs that should characterize our administrators.

Most of the candidates consider the tests fair and searching. They seemed to enjoy themselves, so far as any examination can be enjoyed.

REMUNERATION OF GENERAL PRACTITIONERS

ARRANGEMENTS UNDER N.H.S.

The following explanatory notes have been issued by the Ministry of Health for the guidance of practitioners:

The standard of remuneration proposed for general practitioners taking part in the National Health Service is based on recommendations made by a committee under the chairmanship of Sir Will Spens. The Spens Committee was appointed in February, 1945, and was asked to recommend the right standard for remuneration of “a registered medical practitioner in any publicly organized service of general medical practice.” The Committee was half medical and half lay, and the findings were accepted and published by the Government in May, 1946. [The Spens Report was printed in full in the *Supplement* of May 18, 1946.]

The original proposal made by the Minister of Health was that remuneration for a general practitioner should take the form of a fixed annual payment of £300 per annum plus a capitation fee of 15s. 2d. (based on 95% of the population using the Service—higher if less than 95% use the Service). But to counter the doctors’ fears of this leading to a full-time salaried service the Minister announced in the House of Commons on April 7, 1948, that he was prepared to alter this. [This statement by Mr. Bevin appeared in full in the *Journal* of April 17 at p. 763.] The Minister made the following suggestions:

1. Doctors in established practice may elect either to have a fixed annual payment only or to have the fixed annual payment plus a capitation fee at a proportionately lower rate—subject to conditions to be discussed with the profession, to avoid the individual doctor being disadvantaged by the expense of other doctors.

2. All new entrants to general practice as principals should have a fixed annual payment of £300 per annum, plus the capitation fee, for a period of three years.

3. After three years doctors under (1) may choose which method of remuneration they prefer, i.e., £300 per annum plus a lower rate of capitation fee, or a higher rate of capitation fee only.

Doctors under (a) are free to change from one system to the other at any time. The fixed annual payment of £300 will normally be subject to the condition that the practitioner shall have not less than 500 patients on his list within two years of his inclusion in the medical list as a principal. Taking the annual payment of £300 plus capitation fees at the lower rate (say 15s. 2d.), here are some examples of what, approximately, a general practitioner would be paid under the National Health Service, apart from any extra fees (see below) he would get:

No. of Patients on List	2,000	2,500	3,000	3,500	4,000
Capitation payments	£ 1,516	£ 1,895	£ 2,275	£ 2,654	£ 3,033
Fixed annual payment	300	300	300	300	300
Expenses (say 2%)	726 (40%)	878 (40%)	969 (37%)	1,034 (35%)	1,111 (33%)
Net payment	1,090	1,317	1,606	1,920	2,222

The general practitioner who chooses to be paid wholly by capitation fee would probably earn about the same amount, although generally the fixed annual payment plus the lower capitation fee will be slightly more favourable to the practitioner with the small list and the plain capitation fee to the practitioner with the large list. There are also many possibilities for a doctor to add considerably to his earnings within the general medical and maternity services. Some of the actual figures cannot yet be given, as Regulations have yet to be made, but at present it can be said that the individual doctor’s income may be increased in the following ways:

1. Mileage payments.

2. “Inducement” payments. There will be a fund of over £400,000 a year for extra payments to doctors who practise in difficult and unpopular areas.

3. Training of assistants. Grants for supervision will amount to £150 per annum plus the salary of the assistant and boarding expenses (together not exceeding £700 a year) and an allowance not exceeding £150 a year if an additional car is necessary.

4. Fees for obstetric services. Where a doctor provides ante-natal care, attendance at the confinement (if necessary), medical supervision of mother and child during the puerperium, and post-natal care—7 guineas. A reduced fee will be paid where the patient changes her doctor or discontinues treatment before the services are complete.

5. Payments in respect of drugs and dressings which a doctor is required to supply on the spot. The rate will be 2s. 6d. per annum (or more in certain areas) for every hundred persons included on his list.

6. Payments for drugs, etc., where the doctor dispenses by arrangement with the Executive Council, either on the basis of the actual drugs and appliances he supplies or at a flat rate per annum in respect of each person on his list, with additional payments for specially expensive items.

7. Doctors providing general medical services or maternity medical services and assistants in the employ of such doctors come within the scope of the Superannuation Scheme set up under the National Health Service Act. A doctor will contribute 6% of his net annual receipts from the Service and the Exchequer will contribute 8% of those receipts. In return, after a qualifying period of five or ten years a doctor will be entitled to a wide range of benefits, including (after five years) a lump sum on death or on retirement after age 60 or on incapacity, and (after ten years) on retirement a pension and lump sum, and on death a death benefit and a widow’s pension, the amounts depending on the number of years for which he has contributed.

Miscellaneous Payments

Apart from all these receipts in respect of general medical and maternity medical services, doctors may have income from, for example, the following sources:

1. If the general practitioner is in practice as a principal before the appointed day, he is entitled to get interest at 2½% on the unpaid compensation money.

2. Fee for general practitioner working in clinics of local health authorities. Current fee is £2 5s. a session.

3. Fees for general practitioners on medical boards for Government departments, insurance companies, etc. Current fee

for medical practitioners on Government boards is about £2 12s. 6d. a session.

4. Fees payable by local health authorities under the Midwives Acts where the doctor is called in by a midwife and the obstetric fees mentioned above are not payable.

5. Fees from private patients.

N.H.S. and National Insurance

As much confusion appears to exist between the National Health Service Act and the National Insurance Act, the following explanation may be helpful. There is no need to have any insurance qualification to use any or all of the services within the National Health Service. This means that every man, woman, and child in the country, *without any exception*, whether within the National Insurance Scheme or outside it, is eligible for *all* the health services. There is no age bar, so the new Service is open to old folk just as it is to any other members of the community. About five-sixths of the total cost of the National Health Service will come from taxation in the ordinary way, and only one-sixth comes from the National Insurance Fund. Of an insured man's contribution of 4s. 11d. per week under the National Insurance Scheme, only 8½d. goes towards the cost of the Health Service, and 4s. 2½d. is to cover him for cash benefits—retirement, widows' pensions, unemployment, sickness, and disablement benefit, and so on.

AFTER THE APPOINTED DAY POSITION OF PATIENTS

The following statement has also been issued by the Ministry of Health as an indication to patients of the changes that will take place on July 5 under the National Health Service as compared with the present position under the National Health Insurance Scheme.

N.H.I.—Only 20 million persons in England and Wales—mainly wage-earners—pay insurance and thereby get the services of a doctor without charge.

N.H.S.—Over 40 million people—i.e., every man, woman, and child in England and Wales—will be entitled to the services of a doctor.

N.H.I.—Compulsory insurance is paid by all manual workers and by non-manual workers earning up to £120 per annum (in a few cases there are exceptions), but doctors' bills must be paid for wives and children of insured persons (unless the wife is an insured person in her own right).

N.H.S.—The new scheme is comprehensive. No one at all need have any more doctors' bills to pay. Moreover, the National Health Service will provide *all* forms of medical advice and care—hospital and specialist as well as a family doctor—and it will not depend upon insurance qualification.

N.H.I.—You are free to choose any doctor able to look after you so long as he takes insured patients.

N.H.S.—Freedom of choice remains for both patient and doctor.

N.H.I.—You may change your doctor, but, unless the first doctor consents, you can only change at the end of March, June, September, or December, and then only if you have given at least one month's notice.

N.H.S.—You may change your doctor whenever you wish, without notice.

N.H.I.—Treatment is personal and confidential.

N.H.S.—It will remain personal and confidential.

Dental and Ophthalmic Services

N.H.I.—Dental service is an "additional benefit" provided by some but not all Approved Societies out of surplus funds. A qualifying period is often necessary. A few societies pay the whole cost, but the majority pay about one-half or two-thirds of the cost. About half the insured population is covered.

N.H.S.—Although you may not be able to get full dental treatment without waiting, owing to a shortage of dentists, all dental treatment provided under the scheme will be free of

charge with the exception of treatment or dentures which are more expensive than are clinically necessary and replacements due to carelessness. There will be about 4 million dentists' bills per annum met under the new scheme. There will be no qualifying period. There will be no forms to obtain. Your dentist will have a form, and at the start of treatment all you have to do is sign your name on it. Special arrangements will be made for priority treatment for expectant and nursing mothers and young children.

N.H.I.—The same applies broadly to ophthalmic benefit, which is also an "additional benefit."

N.H.S.—All ophthalmic services will be available to everyone. There will be no "waiting period." About 3 million pairs of spectacles are expected to be issued free of charge each year. There will be a range to choose from, but a charge will be made for special types which are more expensive than the standard types, and for replacements or repairs due to carelessness.

Deaf Aids

N.H.I.—Deaf aids are provided by some Societies which give "additional benefits"; contributions towards the cost of such appliances are made according to the funds available.

N.H.S.—Specialist ear clinics will in time be set up at hospitals. A beginning will be made as soon as possible with the distribution of hearing-aids, and the number will be increased as supplies become available and the Service is developed. Batteries and maintenance will be provided without charge.

N.H.I.—Fees are charged for ambulances by many Local Authorities. Societies sometimes pay travelling expenses incurred in obtaining treatment which is provided as an "additional benefit."

N.H.S.—Local Health Authorities will provide ambulance service without charge.

N.H.I.—Medicines necessary for treatment which are prescribed by doctors are issued free of charge to all insured persons.

N.H.S.—All medicines necessary for your treatment which are prescribed by your doctor will be supplied without any cost or other limit.

Hospitals and Convalescent Homes

N.H.I.—Payments towards the cost of hospital (in-patient) treatment and convalescent home treatment are made by some Societies as an "additional benefit." The cost of specialist services received in hospital may be included in the cost of hospital treatment and paid for by the Society.

N.H.S.—All hospital treatment, including surgical operations and the help of consultants and specialists, will be provided. Your doctor will arrange for you to see the specialist when necessary and also fix your hospital accommodation.

N.H.I.—Medical and surgical appliances are provided by some of the Societies which give "additional benefits"; contributions towards such appliances are made according to the funds available.

N.H.S.—Appliances which are medically necessary will be provided; only in cases where the patient wants a more expensive type will a charge have to be met.

N.H.I.—Payment towards the cost of convalescent home treatment is made by some of the Societies which give "additional benefits."

N.H.S.—Convalescence for hospital patients needing regular care during recovery will be arranged. Facilities will be limited at first. A more general after-care service in the home will be provided by Local Health Authorities.

Other Points

Domestic help is provided in the home by some Local Authorities in cases of illness or maternity. A charge is made according to means. The existing arrangements will be taken over and expanded, the charge continuing to be made according to means.

Health visitors are primarily concerned with the care of mothers and children. Health visitors' work will be extended to cover the health of the entire household, including preservation

of health, precautionary measures, and health education. The health visitors will work in close co-operation with the family doctor.

Many mentally ill or mentally defective people are in work-houses. Others in institutions run by Local Authorities have to pay charges. After July 5 it will be illegal for a mentally ill or mentally defective person to be accommodated in a work-house. All mental hospitals and institutions (except those run for private profit) will be taken over by the Regional Hospitals Boards, and accommodation and treatment will be free of charge.

Mental and physical health are sharply divided at present. As the National Health Service provides for both the mental and physical well-being of the community, much closer co-ordination will be possible.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

ANNUAL MEETING OF BOARD OF GOVERNORS

The annual meeting of the Board of Governors of the London School of Hygiene and Tropical Medicine was held on May 19, when Lord Milverton was elected chairman of the Board in succession to Sir Holburt Waring.

In presenting the annual report Lord Milverton said that this year the report was of a special character intended to celebrate the centenary of public health legislation. About half of it was occupied with a historical review, prepared by a team of students, of the various public health measures from the Public Health Act, 1848, down to the consolidation of social security and medical care by recent legislation. This history had been compiled from contemporary sources (including, as the excerpts showed, the files of the *British Medical Journal*). Lord Milverton also drew attention to an interesting analysis of the subsequent careers of about 500 students of the School who had taken the D.P.H. during the last twenty years. One feature of the analysis was the much larger proportion of students in post-war than in pre-war classes entering academic research and industrial medicine.

Prof. J. M. Mackintosh, the Dean of the School, mentioned various staff changes, including the appointment of Prof. E. T. C. Spooner to the chair of bacteriology and immunology, the conferment of the title of professor of bacteriology as applied to hygiene on Dr. J. C. Crumckshank, and of reader in medical mycology on Dr. J. T. Duncan. Prof. N. Hamilton Fairley had succeeded to the directorship of the department of clinical tropical medicine. Prof. G. S. Wilson had left the School to take up the key appointment of director of the National Laboratory Service, and Sir Philip Manson-Bahr's period of distinguished service to the School, for which he would be long remembered, had come to an end.

Research on Malaria Transmission

The Dean went on to say that the present year marked not only the public health centenary but the jubilee of Ross's discovery. It was appropriate in such a year that the School should have been associated with an important discovery in malaria which Prof. H. E. Shortt and Dr. P. C. C. Garnham had done much to further. This was the attempt to discover the pre-erythrocytic stage of mammalian malaria. The first success was obtained when pre-erythrocytic parasites were discovered in the liver of monkeys suffering from monkey malaria due to *Plasmodium cynomolgi*. The first forms seen were those present on the seventh day of the incubation period and represented developing schizonts of large size found in the parenchymal cells of the liver. Afterwards the earlier and later stages of the development, from the fifth to the tenth day, were also obtained. Following up this discovery, an attempt was made to discover similar forms of human malaria with the assistance of the Malaria Unit of the Ministry of Health at Horton Hos-

of *P. vivax* of man was discovered. As expected, this was found to be similar to the form previously found in monkeys. O. application of this finding was that in future the action of drugs intended to produce causal prophylaxis could be checked by visual observation of the pre-erythrocytic forms.

At the chairman's invitation Dr. Garnham gave the meeting a brief demonstration, with lantern slides, of this piece of work. For the experiment at Horton a willing volunteer was secured. He was heavily infected with *P. vivax*, and later he was operated upon by Mr. Radley Smith and the material examined by Prof. Shortt and Dr. Garnham. The similarity of the happenings in man to those in the monkey was fully confirmed. It seemed likely that this discovery might lead to new advances in knowledge of the treatment and prophylaxis of malaria and of its immunology.

Continuing his review of the School year, the Dean referred to the gradual resumption of pre-war activities in the department of bacteriology and immunology, where heavy teaching duties had left little time for research; the work on nearly 1,500 mycological specimens received for diagnosis in the sub-department of medical mycology; the investigation of mould metabolic products in the department of biochemistry, and other work in the departments of entomology, of applied physiology, and of human nutrition. The department of public health had had an unusually large registration of students for the diploma. During the spring term of 1947, when practical work was being done with medical officers of health, it became necessary to arrange for the distribution of students in six boroughs in London or Greater London in addition to rural work and special visits.

Reference was also made to the acquirement of Winches Farm, St. Albans, as the Field Station of the School. The work on plant helminthology and the workers concerned had been transferred to Rothamsted. At Winches Farm the breeding of laboratory animals on a scale sufficient to supply the wants of the various departments of the School had been begun.

TRAINING IN CHILD CARE

CONFERENCE IN LONDON

A conference organized by the National Society of Children's Nurseries was held at the London County Hall on May 21, when the need for training in child care, teamwork in child health, and administrative problems in training the nursery nurse were discussed. The conference was largely attended by members of local public health departments and voluntary services from all parts of the country.

Alderman Reginald Stamp, chairman of the Health Committee of the L.C.C., said that his Council had been responsible for the development of some very fine residential nurseries, and on the "appointed day" it would inherit the day nurseries at present owned and controlled by the 28 Metropolitan boroughs, with their visiting doctors, nurses, and health visitors. Many nurseries were in improvised and unsuitable accommodation, and his Council was "moving heaven and earth" to obtain additional premises. He saw an opportunity through the new Regional Hospital Boards for developments in nursery work in districts where so far it had hardly gained a footing.

An address on the need for preparation in child care was given by Dr. William Moodie, of University College Hospital. Some people supposed, he said, that with the ordinary girl the play of her maternal emotions would be sufficient to enable her to undertake child care, but that was seldom true. The maternal instinct in a young unmarried girl was immature; she was likely to be attracted to the child as if it were a living doll rather than a person, and even the youngest children were persons. For the natural development of the child it was necessary that he should have emotional security, affection, that is to say, the assurance that he was loved, and some outlet for his energies in the form of work. In his psychiatric clinic he constantly saw children who were emotionally unbalanced because their energies had not been recognized and used, so that the overplus of energy went to the emotional side and ministered to fear and anxiety. Anxiety, after all, was only the state of not knowing about things; once knowledge was imparted, whilst there might be disappointment or vexation, there was no further anxiety. Dr. Moodie spoke also of the need for the child's

The pre-erythrocytic stage was the subject of an article in the *British Medical Journal* of Jan. 31, 1948, and a preliminary account of the work of the London School of Hygiene and Tropical Medicine appeared in the issue of

to be stable and well adjusted, to maintain an objective attitude, and to refrain from using the nursery as an outlet for imbalanced or unsatisfied emotion in herself.

Need for Teamwork

The need for teamwork in child health was emphasized by J. D. Kershaw, M.O.H. for Colchester, who said that it only during the last forty years or so that there had been constructive effort in the direction of child health—an effort which took the form not merely of supervision with the aim of preventing disease but of making the most of the capacities in which the child was endowed. For this purpose the family needed some assistance from outside. While the mother might be able to detect some departure from normal health in the child, she was not trained to detect minor but none the less significant deviations. The family needed help in this respect, the help must not be such as to relieve the family of all responsibility. Three agencies were concerned with child health, the home, the nursery or school, and the medical service. These must work together. He illustrated how effective such cooperation might be in dealing with squint, speech defects, bad posture. He spoke against a sudden and automatic break between nursery and infant school at the age of 5; transition should be graduated between 4 and 6. A nursery which was used as a parking place for the child, and nothing else, was breaking up the family. Dr. Neil R. Beattie, senior medical officer, Ministry of Health, said that, although child care had developed beyond all imagination, yet with all the advances large problems remained. Proof of which it was necessary only to point to juvenile delinquency and the conditions set out in the Curtis report. Many illiterates and semi-illiterates were still to be found, and a great deal of maladjustment in after-life derived from lack of proper child care. He spoke of the adult attitude towards the child and of the need for an enlargement of the conception of child care beyond the satisfaction of physical needs and instruction. Dr. Elizabeth Findlay discussed administrative problems in training the nursery nurse, and there was a useful exchange of constructive opinion and experience on the value of training in child care.

HUMAN FACTORS IN INDUSTRY

BRITISH ASSOCIATION CONFERENCE

The British Association for the Advancement of Science held its conference on "Human Factors in Industry" at the Assembly Hall, Leamington Spa, on May 8. Sir Henry Tizard presided over the first session on working conditions and Sir George Colchester took the chair at the second session on human relations.

Prof. R. E. Lane in his introductory survey said that the contribution of the doctor to industrial health must be, in the first place, on the educational side. The failure of both industry and of municipal undertakings to use the vast amount of information available on human industrial problems was due often to ignorance rather than wilful neglect. There was still not enough co-operation between industry and research organizations. Work undertaken by the Industrial Health Research Board might not have appeared to the practical man to have obvious applications in industry. Research workers should bear this in mind and approach realistically the problems which faced industry.

The doctor was also responsible for seeing that the worker was fit for the job and that the job was fit for the worker. The medical assessment of the workman should have its counterpart in job analysis with a physical and psychological assessment of the needs of the job.

Co-operation was needed between medical scientists and engineers in the design of plant. Other problems which would engage the attention of the doctor in industry were resettlement after illness or accident; casualty services, which must be of a high standard; and certain ancillary services such as ophthalmology and chiropody. The hazards of occupational disease applied to a comparatively small number of men in industry, but the reassurance provided by skilled medical care had an important effect on the morale of other workers. The

doctor must win the confidence of employer and employees. He should help to settle the conflicting claims of, say, the industrial psychologist and the production engineer. He needed much knowledge of industry and of industrial processes and a profound knowledge of people.

Coal-mining

Dr. C. L. Cope said that in coal-mining in Britain deaths on the job averaged about 550 per year. Accidents sufficiently severe to cause an absence of more than three days numbered 180,000 per year and had been increasing steadily for a number of years. Certifications of incapacity on account of pneumoconiosis numbered about 4,000 per year and this incapacity was, of course, permanent. Certifications for nystagmus numbered 1,800 per year and for dermatitis 1,000. There were relatively few places where the effective working temperature exceeded 82° F. (27.8° C.), the temperature at which efficiency began demonstrably to deteriorate, but dust and darkness persisted although big efforts were being made to overcome them.

The number of cap lamps in use had risen from 1 per 100 men in 1928 to 34 per 100 in 1946, and the efficiency of these lamps was being steadily improved. Fluorescent lighting had now been installed not only in haulage ways but also at the coal-face in several collieries. It had not yet been possible to assess the effect of different methods of lighting on the incidence of nystagmus and on accident rates. Attempts were now being made to introduce a uniform method of recording accidents in collieries throughout the country.

Increasing mechanization had tended to increase the amount of dust in the mines, but this was now being reduced by spraying with water or with water and wetting agents or with foam. In one colliery in South Wales effective dust suppression by spray and infusion was started in 1942. Dr. Jenkins in a survey of several hundred miners was able to collect two small groups: one group had worked in the pit in the pre-1942 dusty days for up to five years and the other group had only worked there in the relatively dust-free period. Of the former group of 18 men, 17 showed Grade I or Grade II lung changes; of the latter group of 22 men, after up to five years' exposure, none showed any radiological changes. Dr. Cope concluded by saying that improved environmental conditions would bring better physical health, but the medical profession was now more aware of the importance of mental health and of the way in which this was influenced by the human rather than the physical environment.

Heating and Ventilation

Dr. T. Bedford, who contributed the last paper in this session, discussed some of the problems of heating and ventilation. Recent work suggested that as a general rule fresh air should be supplied at the rate of not less than about 600 cubic feet per person per hour, and that preferably there should be 1,000 cubic feet per person per hour. The Factory Department pamphlet on the ventilation of factories recommended a ventilation rate of six air changes per hour. In most instances this represented good ventilation, and if such a rate could be maintained it would probably provide a reasonably clean atmosphere from the standpoint of bacterial contamination.

For persons doing very light work the air temperature during the winter months should be as nearly as possible 65° F. (18.3° C.). It was undesirable that it should fall below 60° F. (15.6° C.) or exceed 68° F. (20° C.). The 1937 Factories Act required that in rooms where a substantial portion of the work was done sitting and did not involve serious physical effort the temperature must not be below 60° F. (15.6° C.) after the first hour of work. For more active work somewhat lower ranges of temperature were sufficient. For active yet light work a temperature of 60° to 65° F. (15.6–18.3° C.) was suitable, while for work requiring more muscular exertion a temperature of between 55° and 60° F. (12.8–15.6° C.) was desirable.

Even at ordinary room temperatures a high atmospheric humidity tended to cause feelings of stuffiness. At such temperatures the moisture content of the air should not exceed 70% of the saturation value, and should preferably be well below that figure. In the average factory where there were no wet processes the humidity would generally be satisfactory if the fresh air supply was adequate. Discomfort was felt when the wet-bulb temperature exceeded 70° F.

When a task required considerable manual dexterity uncomfortably low temperatures were undesirable, for as the hands became chilled their dexterity diminished. In one series of experiments the investigators imitated an industrial process by assembling the links of a bicycle chain. When the room temperature was 50° F. (10° C.) the time required to perform the test was 12% longer than when the temperature was 62° F. (16.7° C.). In another series of laboratory experiments the effect of temperature on the work done by a group of men while weight-lifting was studied. The men worked at their own discretion and were paid a bonus on the amount of work done. At a temperature of 75° F. (23.9° C.) they did 15% less work than at 68° F. (20° C.). Other observations had shown that when work was done at a constant rate an increasing strain was imposed on the body as the temperature of the environment rose.

Dr. Bedford also discussed the effect of temperature on accidents, particularly in coal-mining, and on industrial sickness. Steel smelters had a sickness rate 23% greater than that for the whole body of workers, and the rate for puddlers was 20% greater. Tinplate-mill men and rolling-mill men had sickness rates 18 and 8% above the average. He concluded by saying that the ventilation and heating of a factory should be under the effective supervision of one person who had been trained to pay special attention to the proper use of the appliances and arrangements provided. Particular care should be taken to ensure that the temperature was suitable for the work which had to be done, and that overheating was avoided. Unduly low temperatures at the beginning of the day and excessive warmth later were still too often observed. These troubles could be avoided by adequate supervision.

Human Relations

In the second session the introductory survey was given by Dr. T. G. Tredgold, and he was followed by Mr. D. Chapman, who discussed incentives.

Mr. Chapman pointed to a number of factors which suggested that the national morale had declined over the last thirty years. He thought that tackling production problems by exhortation on a national scale had had little or no effect, and might even have had a bad effect. In the final solution financial incentives would play an important part, but their effectiveness would depend on the total situation. Good management, intelligent and sympathetic foremen and departmental managers, democratic participation of workers in management, and effective but not paternal welfare schemes were all as important in their way as satisfactory lighting, heating, and sanitation.

The problem of deterrents was considered by Dr. A. T. M. Wilson. Among other things Dr. Wilson said: "It is an almost universal feature of industrial concerns that reciprocal scapegoating systems have been developed and that they are often heavily sanctioned on what is alleged to be a basis of experience. It may be wise to remark in passing that such systems are not confined to the industrial world but are a universal human phenomenon." He had found that pep talks worked in the opposite direction to that in which they were intended. Autocratic practice—and the expectation of it—was so deeply entrenched in industry that any attempt to change towards a more co-operative state of affairs was likely to be met with considerable scepticism, which must be accepted and understood. In disposing of conditions acting as barriers to co-operation in industry a start could be made almost anywhere and by anyone, provided that those who sought to make changes were men of integrity and sincerity of purpose. Not enough was known in the scientific sense about industrial problems of this kind, and this he regarded as a justification for active research and not for inactivity. But there was a danger that the scientific method might be discredited in human affairs, and particularly in industrial problems, because it was too often inadequately applied.

The Central Council for Health Education has completed arrangements for its annual summer school in health education at "High Lodge" Hotel, Herts, from Aug. 11 to 25 (*Journal*, Jan. 10, 1948). A few places are not yet taken, and information may be obtained from the Medical Adviser and Secretary, Central Council for Health Education, Tavistock House, Tavistock Square, London, W.C.1. The total cost of the course per person is 16 guineas.

Reports of Societies

RADICAL EXCISION IN CARCINOMA RECTUM

In the Section of Proctology of the Royal Society of Medicine on March 19, with Mr. DICKSON WRIGHT in the chair, subject for discussion was radical excision of carcinoma of the rectum, with conservation of the sphincters.

Prof. G. GREY TURNER referred to the operation which older generation associated with the name of Prof. Hartmann. A section of the bowel was removed as thoroughly as in other operation, but the mucous membrane at the lowest of the rectum was denuded from its sheath and the bowel drawn through the sphincters and sutured to the anal ring. He could not forget seeing in 1931 the demonstration of Hartmann of this operation and the care and thoroughness with which he carried it out. He had had the opportunity of examining one or two cases in which the operation had been done two or three weeks previously and was able to observe the perfection of the sphincter apparatus. He gave statistics of a group of 17 cases, in 14 of which there was a malignant condition; 6 had died with recurrence or dissemination within 5 years, but 7 were alive and well more than five years after operation.

The operation was very satisfactory in dealing with frankly non-malignant conditions, for example papillomata. The type of bowel removed depended to a certain extent on the size and type of growth. It was necessary to pull down the upper bowel so that an anastomosis could be made without tension. It was not an easy manoeuvre, it took a long time, and the surgeon must satisfy himself that enough bowel had been excised. A point to be considered was stenosis. Where there was stenosis one could dilate with the finger or an instrument, and then instruct the patients to give up what they took to make a stool fluid. The stool then, being solid or semi-solid, acted as a natural dilator. None of his patients had had a permanent stricture; most of them had as good control as before operation. Prof. Grey Turner added that he was not fond of methods of irrigation, but he could not forget the wonderful results which Gordon-Watson brought before the Section some years ago. There might be other methods of using irrigation which could be combined with an operation of a radical nature. Some people were very satisfied with colostomy, but he thought that patients dreaded it, and also that it was regarded with misgiving generally by surgeons.

Technique and Results

Prof. C. A. PANNETT said that for many years in this country and in America the surgery of carcinoma of the rectum had been dominated by the personality of the late Ernest Miles. Everybody recognized the great work he did and the correctness of his observations; where he went wrong, or where others who followed him went wrong, was in the deductions from those observations. It was true that with patients dying of carcinoma of the rectum the growth spread outwards and downwards, but in the operable case, when the disease was at a stage at which the growth could be removed and a conservative operation done, this was not likely to be the method of spread, which might be upwards only. Prof. Pannett then proceeded to deal in detail with various points of surgical technique. He seldom did a colostomy before operation. There were cases where the growth was too low to be dealt with from above, and then he thought it right to do the combined operation which he had described in 1934, but the longer he went on the more patients he found who were capable of being treated by the one operation alone. In conserving the sphincters a great amount of the work of the operation was eliminated, and if it could be done from the abdomen the patient was less shocked. Prof. Pannett concluded by saying that he had lived to see the hollowing of cherished surgical beliefs demonstrated and to feel that scientific advances could be made only if they regarded their contemporary beliefs as always wrong or at best as half-truths; but when he considered patients who had undergone this operation and had lived twelve or fifteen years of perfectly normal life he could not help feeling that the foundations of the operation could be placed among the dependable half-truths.

Mr. O. V. LLOYD-DAVIES said that it had always been one of the aims of the surgeon to remove growths without the necessity of permanent colostomy. Some in the past had relied upon colostomy, since it was realized that increased gas tension might be the determining factor in success or failure. Few considered the advisability of transverse colostomy, which was a distinct advance towards safety. With regard to the combined excision operation as performed by Ernest Miles, figures from many clinics suggested that 50% of five-year cures was about the best which could be attained, and only early diagnosis would improve the results. Mr. Lloyd-Davies showed specimens of cases where wide removal had been done, but in spite of this there had been recurrence two or three years later. He entered into details of the three types of operation which were performed at St. Mark's, and concluded by saying that a high local recurrence rate was too big a price to pay for the avoidance of a permanent colostomy. These patients must be followed up for the rest of their lives.

The discussion was continued by Mr. NAUNTON MORGAN and Mr. W. B. GABRIEL. Mr. J. P. LOCKHART-MUMMERY said that when he started on this line of work the chief consideration was mortality, which at that time at St. Mark's and anywhere else was about 85 or 90%. By using the Hartmann operation mortality was reduced to more reasonable proportions. Next came the question of recurrences; a careful selection of cases for the combined operation had reduced the recurrence rate quite considerably, so that to-day a patient who had to face an operation for carcinoma of the rectum had a very good chance of only surviving but of having no recurrences. The new problem was whether as good results could be obtained by an operation which did not involve a permanent colostomy. This had not yet been achieved, but it would be done, and the only way to tackle it was the way in which Mr. Lloyd-Davies and Mr. Morgan were tackling it, namely, by scientific methods and by careful examination of their procedure and their specimens.

MILLION-VOLT THERAPY AT ST. BARTHOLOMEW'S

Analysis of Results

A report on the million-volt therapy installation at St. Bartholomew's Hospital was given at a meeting of the Section of Radiology of the Royal Society of Medicine on May 21, with Dr. J. S. FULTON presiding.

Mr. G. S. INNES, physicist in charge of the installation, said that the experiment at St. Bartholomew's began in 1936 with an installation for 600,000 volts, which operated successfully initially at 700 kV, and later, in 1939, this was stepped up to one million volts. He described and illustrated the various details of the equipment. Among other matters he mentioned that the tube was about 30 ft. long and weighed 12 tons, and, inasmuch as it was impossible to adjust the tube to the patient, the floor was made movable up and down, and the movements were nearly as simple as those of a normal free-moving x-ray tube. The installation had operated almost non-stop since 1939, with only one major shut-down of one afternoon, though occasionally it was stopped for an hour and a half while a rectifier filament was changed. During the war, although the department lost its ceilings, windows, and doors, and on one occasion part of its roof, the plant was never out of action. In the clinical experiment which was undertaken it was realized that the applicators would become too heavy at a million volts, and therefore a diaphragm system was installed, giving some 450 different field sizes.

The main physical advantage gained by the installation was the increased depth dose, particularly with small fields. He gave a comparison of the transmission through various substances as between the million-volt installation and the 200 kV. In thick bone, such as the shaft or head of the femur, with 200 kV there was 86% transmission (compared with water), whereas with the million-volt installation the transmission was 95%. The installation also allowed the use of large doses without damaging the skin. Again, with unilateral lesions, often it was not necessary to irradiate the other side of the patient. Mr. Innes concluded by expressing his great indebtedness to the eight medical officers with whom he had worked, for the understanding they had shown of the physical problems encountered in such an experiment.

Reactions

Dr. ARTHUR JONES gave a brief account of the effect of these radiations on the patient and of the relatively few unfavourable reactions which had been met with in the use of the plant for the treatment of malignant disease. A voluminous literature had been accumulated on the variation of skin response to x-ray treatment. The skin dose, fractionated over 3-5 weeks, for a second-degree erythema lay between 4,000 and 5,000 r. Erythema developed more slowly than with 200 kV, and reached its maximum later. In the deep-therapy range the factor limiting the radical treatment was often the severity of the skin reaction. But the million-volt therapy might produce a "treatment-limiting" mucosal reaction in the vicinity of the tumour. This was observed particularly in the pharynx and larynx and in the pelvis. In the pelvis these mucosal reactions might affect bladder, rectum, and vagina. As for general reactions, radiation sickness did occur in patients having supervoltage therapy, but was probably less frequent than at 200 kV. In the Year-Book of Radiology in 1937 the editor observed that presumably the operators of the then projected million-volt plant would familiarize themselves with the not always happy effects of supervoltage therapy which had been recorded in America. This had been done, but relatively few severe injuries had occurred at Bart's, and this was a tribute to the careful planning of the treatment of each individual case by Mr. Ralph Phillips and Mr. Innes. Skin reactions had often left a mild chronic radio-dermatitis as a sequel. Skin atrophy was less common than with the 200-kV therapy, but fibrosis and oedema giving a leathery skin were not infrequently encountered. Subcutaneous fibrosis affecting fatty tissue was also more common. A true radio-necrosis was of rare occurrence, but the incidence of necrosis after irradiation of anal canal tumours was unfortunately high, developing in 5 patients out of a total of 23. Muscle fibrosis occurred in the neck: in 3 out of 15 cases treated for thyroid carcinoma. Irradiation of the oesophagus for carcinoma had resulted in rather dramatic sequelae in two cases. One of these was in a man aged 57 who was given a tumour dose of 5,200 r in 35 days by six fields for carcinoma of the middle third of the oesophagus. The clinical response was good, but two months later he died of a sudden haemorrhage. The oesophagus and the aorta were found to have communicated through a large hole: there was no sign of growth nor any evidence of necrosis above or below the perforation. Here again he felt that they were dealing not so much with a true necrosis as with a failure of the reparative processes. The other case was somewhat similar. Possibly with some different method of fractionating the dose such a disaster might be avoided in the future. A most unusual case of fatal hepatic disorder occurred during irradiation for bronchial carcinoma. The patient was given 4,500 r in 25 days. It appeared subsequently that during the irradiation he was incubating chicken-pox. Post-mortem examination revealed gross abnormality of the liver.

Results of Treatment

Mr. I. G. WILLIAMS gave an analysis of the results of treatment. Five main types had been chosen for analysis: carcinoma of the breast, inoperable, but without distant metastases; carcinoma of the cervix in all stages; carcinoma of the upper air passages; inoperable carcinoma of the rectum; and carcinoma of the oesophagus. Research had been handicapped by the war; on humanitarian grounds it had been necessary to treat patients other than those in these classes. It had been the policy at St. Bartholomew's to treat early malignant cases by surgical rather than by radiotherapeutic methods; thus the patients who were referred for million-volt therapy were incurable by any other means because of the nature of the tumour, its anatomical extent, or the general condition of the patient. Less than 5% fell into a really operable category. Their experience emphasized clearly that early disease could be cured and that late disease could not be cured, though considerable palliation could be offered.

The number of cases available for analysis was 726. A few of the patients were untraced, and these were counted as dead, and therefore to that extent the figures were weighted against the therapy. Mr. Williams said that in cancer of the breast he could confirm Phillips's observation that disappearance of the primary tumour and the regional lymphatic metastases was

more certainly and easily obtainable with supervoltage than with ordinary deep x-ray therapy. Of 14 patients with advanced carcinoma of the tongue all were dead: 9 died in the first year, 3 in the second, one in the third, and one in the fourth. In 6 cases the primary growth regressed before the patient died from metastases. Between 1939 and 1945, 20 cases of carcinoma of the antrum were treated, 13 of them primarily by irradiation. Of these 13, 4 were alive—one in the eighth year, one in the fifth, and two between the third and fourth. The average dose given in these cases was 4,500 r in 21 days. There were 34 cases of extrinsic growth of the larynx; 2 were moribund on admission. Of the 32, 3 had survived—two of them for five years or over, and the third was about to reach the fifth year. Of 20 cases of intrinsic carcinoma of the larynx treated primarily by irradiation, 10 were alive—4 at five years, 4 at four years, and 2 at three years. Of the 10 who were dead, 5 died of the disease, 2 of other causes, and 3 of damage due to treatment.

Carcinoma of the bronchus was treated in 148 cases, in 46 of which the treatment was palliative; of the remaining 102, 100 were dead, and 2 alive, having survived five years and four years respectively. The problem here was not entirely one of dosage, for the cases treated with high dosage had done no better than those treated with low dosage. The relief of symptoms, however, was very real.

Of 40 patients with carcinoma of the bladder, 5 died within three weeks; of the remaining 35, 8 were alive and 27 dead. In only one case was the bladder severely damaged by the treatment. Of 23 cases of squamous-celled carcinoma of the anal canal, 5 had a serious radiation necrosis, which was probably responsible for the death of one patient. Out of 11 of these patients who were treated five years ago 3 were alive and well. One patient died in his fifth year without any symptom referable to the anal canal; two of the survivors had strictures, both necessitating colostomy. The number of cases treated for carcinoma of the rectum was 192, and the total number of survivors was 20. In 42% there was relief of the symptoms which were due to the primary growth, and 60% of the patients were quite comfortable until they died of metastases. Of 16 patients with cancer of the thyroid, 4 survived for periods of eight, seven, five, and four years, respectively.

In comparing the results with those obtained by the use of 200-kV therapy, there appeared to be no very marked differences. Tumours which responded poorly to ordinary radiation treatment showed little difference in their response to million-volt therapy, with the possible exceptions of cancer of the bladder, rectum, antrum, and larynx. There was no doubt that every radiotherapeutic department should have a high-voltage machine to increase its range of usefulness. With such equipment more could be done for some of the cases, and the application was made more easy for the patients and also for the technicians and physicists. It was disappointing that the results were not better, but that was the tale they had to tell.

Higher Voltages

Dr N. S. FINZI recalled that in his Mackenzie Davidson Lecture to the British Institute of Radiology some fifteen years ago he had suggested a test of the higher voltages, and this was made possible at St. Bartholomew's through the generous Sassoon benefaction when in 1936 the department was started for the treatment of patients at 600 kV, and in 1939 was keyed up to a million volts. It was realized from the beginning that no staggering improvement was to be expected. The research was planned to comprise certain definite groups of cases, but unfortunately the war interfered with the programme. The figures were too small to be significant, though they were probably significant for the breast, the antrum, the larynx, and possibly the rectum. The occurrence of necrosis was mostly in the early cases and when large fields were being used. Later, with very small fields, carefully checked by isodose charts, these troubles were reduced. With million-volt therapy these results could be obtained with less damage to normal tissues. Apart from improvement in results, those who worked with this apparatus preferred it to lower-voltage installations on account of ease of manipulation and the greater accuracy obtainable. In some respects enough had been achieved to justify the hope that better results would be forthcoming, and with further

increases in voltage there might be better results still. There was some difference of opinion on whether a big jump in voltage should be taken or intermediate stages should be tried, himself was not in favour of the big jump; the optimum might in that way be missed. He thought they should aim at a plant giving from three to five million volts, and afterwards if it was considered desirable, go up to twenty million. Results obtained with one million volts seemed to indicate that malignant disease should be treated with higher voltages still.

Mr. F. C. W. CAPPS, speaking as a surgeon at St. Bartholomew's, said that in carrying out laryngectomy he preferred pre-operative irradiation. He knew that some preferred radiotherapy to be done post-operatively, but he never regretted arranging it the other way, and he had also found that it made the growth more manageable from a surgical point of view. Dr. T. ANTHONY GREEN, Prof. B. WINDEYER, and the President added some further remarks mostly congratulating those concerned in the Bart's experience.

Preparations and Appliances

AN EXTENSION FOR THE GORDH NEEDLE

Dr. C. F. SCURR, Registrar in Anaesthetics, Westminster Hospital, writes: The apparatus illustrated is intended to facilitate the intravenous administration of anaesthetic drugs during operations in which a vein is not readily accessible to the anaesthetist—e.g., thyroidectomy, radical mastectomy, and operations in the lateral position. On the left is shown an ordinary intravenous needle which is introduced into the chosen vein; this needle is then connected, by means of the nozzle shown, to six feet of the finest "polythene" tubing, at the other end of which is fitted a standard Gordh diaphragm needle.

The Gordh needle is placed in a position convenient to the anaesthetist, who will probably be at the patient's head; usually it is fixed on to the anaesthetic table by strapping.

The apparatus is sterilized by boiling and is filled with sterile normal saline before use. Injections of thiopentone, *d*-tubocurarine, etc., are made with a syringe and needle through the diaphragm in the usual way. If a brand of *d*-tubocurarine is used which is not compatible with a barbiturate, the apparatus is washed through with 2 ml. of sterile saline in between the injections of the drugs; a similar procedure is used to draw through injections of small volumes. As the capacity of the whole apparatus is only 1 ml. the lag is negligible; the resistance to injection is of a similar order to that encountered when making an ordinary intravenous injection. As there is no "backlash" in the system, blood does not enter the intravenous needle and clotting does not occur. In trials on numerous occasions and in very prolonged operations blocking of the needle has not been encountered.

The "polythene" tubing was supplied by Portland Plastics, Ltd. The complete apparatus can be obtained from Medical and Industrial Equipment, Ltd.

Correspondence

Domestic Difficulties in the N.H.S.

SIR.—I have a small house with only two sitting-rooms and hall on the ground floor. It is the only house that I could buy when I returned to practice after the war. The hall is the sitting-room, and for my surgery I use the best sitting-room. My family are restricted to the second lounge and a parlour for meals. It has not been comfortable, but we have managed, although frequently there has been standing room only in the hall. A living-in maid is unobtainable, and the half-day domestic help has not as yet been too difficult about the mud brought in on the patients' shoes. My wife holds the fort while I am out and spends her few moments of leisure in answering the telephone and inquiries at the door, many of which are unnecessary and very irritating.

It is conditions such as these that make many doctors dread life intolerable when, to make a living wage, one will have to encourage mass-production medicine. I would ask our negotiators to urge the Ministry to authorize Local Executive Councils to set up at once National Health Service surgeries conveniently spaced on main bus routes. Such surgeries should not in any way be considered as health centres, which will evolve later, we hope, on an experimental basis. Any ordinary dwelling house will suffice, subdivided into a waiting-room and consulting-rooms, with secretary receptionists, capable of typewriting hospital letters, certificates, reports, etc., two nurses to chaperon women patients and assist in minor operations, and telephonists.

By staggering hours of consultation a number of doctors could be accommodated, and the only equipment required would be a sterilizer, the necessary furniture, and filing cabinets for record cards. Doctors would bring their own instruments and voluntary aid societies would no doubt help to improve the atmosphere by dispensing tea and light literature in the waiting hall. Combined surgeries of this kind would provide more comfort for the patients than I can supply and would be an even greater help to young doctors, who could then live in a hotel or flat until a convenient house was available. The relief and joy of our wives would rejuvenate them and we would all start the N.H.S. in a happier frame of mind.—I am, etc.,

H. W. TOMS.

Leigh-on-Sea.

Questions of the Hour

SIR.—I have refrained from writing to the B.M.J. as there is an intense desire among many members to publish their opinions. However, now that the B.M.A. has decided to yield to the Minister without a fight for our rights, I would like to make the following observations.

I agree it was about time that something was done to rationalize or regularize the P.M.S. and the National Deposit on lines similar to the N.H.I. I also agree that the Spens Report was a fair judgment in so far as the N.H.I. remuneration was concerned. However, we are being paid according to the Spens Report on the basis value of the £1 in 1939 and not 1948. The B.M.A. has made no provision in its stand about protecting our remuneration and the terms of service demanded, but rather has left it to a gentleman's agreement. After the Minister has got his Service going he can reduce the remuneration to 15d. and we can do nothing about it.

Furthermore, I should like to know where I stand about my property before I decide to join the Service. If I continue my practice at my home (which is incidentally specially designed in the best of B.M.A. tradition for the purpose), and should I decide at some future date to resign, have I to get permission from the Minister or his committee before selling my home? If, on the other hand, I decide to rent a shop in the neighbourhood and cease to practise in my home (which, of course, would reduce the facilities or ease for my patients being able to get me), is the sale of my house still subject to the Minister's control? If so, is any other property that I may possess subject to the Minister's control?—I am, etc.,

Enfield, Middlesex.

Simplify the Work

SIR.—Now that it seems probable that the profession will attempt to work this pernicious and ill-considered Health Act, I suggest that our negotiators should insist on making working conditions as easy and simple as possible; otherwise the administrative side is bound to become chaotic.

From the point of view of the G.P. who cannot afford a secretary one or two things are essential. First, they must be allowed a rubber stamp for signatures, then certificates must be reduced to a minimum. This craze for separate certificates which all employers demand must be done away with. There is no earthly reason why the statutory certificate cannot be shown to the employer and noted in his files without a separate piece of paper being issued.

The design of clinical record cards should be made or approved by our negotiators. The card should contain a printed list of (a) subjective symptoms, e.g. pain (location), sleep, appetite, cough, bowels, etc.; (b) objective symptoms, e.g. colour, T. and P.R., fauces, tongue, heart, lungs, other organs. These lists should be printed in the first column of the card, the second and subsequent columns to be used for notes on symptoms under the date. The N.H.I. record cards entailed too much writing.—I am, etc.,

Stone, Staffs.

R MURRAY BARRON.

Division in Profession

SIR.—As probably a last act as Chairman of the Shropshire and Radnorshire Medical Independence Association, I write to protest against your ill-conceived editorial in the issue of May 15, which attempts to see even partial victory for our cause as a result of the recent activities of the B.M.A. Council in wisdom in its rushed and badly timed April plebiscite. Outmanoeuvred, outwitted, and outstampeded, the Council rushed that plebiscite upon us without our having sufficient time to consider and discuss the full implications of the Minister's tardy modifications to certain details of the Act which we could not accept. There is no doubt there should have been insistence on a postponement of the appointed day to permit of this. But this was not done, and, as a result, many areas the profession either voted as stampeded, isolated individuals or refrained from voting their opposition, which had already been so strongly expressed in the February plebiscite. The result is a debacle.

The Representative Body meets, therefore, on May 28 in circumstances which no effort can avail to restore the shattered unit of the profession. We are now in a situation the reverse of democratic in which the majority feel we are being forced to operate an Act by the blind and injudicious votes of a minority and an *ipse dixit* of the Council. Every important and vital matter affecting the future of ourselves and our profession will ever be settled in any satisfactory way. Our boats have been burned before our eyes. Truly, the Representative Body meets in tragic circumstances. We in the provinces have lost faith in our central organization as a negotiating body, and, unless the Representative Body by determined action can to some extent retrieve the situation by insisting on a strength in negotiating hitherto sadly lacking, the B.M.A. as a medium of implementing the will of the profession will meet the fate its great failure has deservedly brought upon it.—I am, etc.,

Shrewsbury.

W. J. GRANT.

Bewilderment

SIR.—May I endeavour to express my complete agreement with Dr. J. McIntosh Rattray's letter (May 15, p. 951) and my bewilderment that so wise and courageous a colleague as Dr. Alfred Cox should advise capitulation (p. 949) on matters of principle?

The leading articles are so brilliantly written that they naturally exercise great influence on the profession, and in the issue of May 15 (p. 936) it is stated that the Minister has offered a compromise, and that compromises are the traditional English way of settling disputes. For the medical profession to reject the compromise and to be intransigent would cost the support of public opinion.

LEON CHALMERS.

The profession compromised (and in my settled opinion committed a fundamental error) when the Representative Body affirmed its desire for a comprehensive service available to everyone, instead of a comprehensive service available to those who needed it. After exhaustive discussion, certain fundamental principles were accepted as essential if there was to be any freedom for the public or the profession. I suggest, Sir, that you are confusing compromise with surrender.

I would like to ask Dr. Cox if he does not think it an extraordinary fact that in spite of the change in lead in the *Journal*, in spite of the persistent State propaganda of the *Lancet*, in spite of the absence of support from any political party and the nauseating exhortation in the House of Lords by Lord Moran, so many of his colleagues are still convinced that to implement the present Act would be a disaster for Medicine and for the happiness of this country.—I am, etc.,

Bournemouth.

E. D. GRANGER.

Comprehensive Service

SIR,—I have read with much pleasure Mr. David Hardie's letter (May 8, p. 898). To my mind he sums up the matter very clearly. Some form of comprehensive medical service I believe most doctors desire, but the crux of the whole matter, as Mr. Hardie states, is that this service, while being open to everyone, should still be one to which everyone is free to subscribe or not; in other words, it should be one which preserves entire both the freedom of the patient and the freedom of the doctor.—I am, etc.,

London, S.W. 3.

BASIL BROWNING.

Extend N.H.I.

SIR,—I wish to express my utter dismay at the puerile and inefficient attempts of the B.M.A. to resist the enslavement of the medical profession. With a display of bravado we, the general practitioners, who are the backbone of any medical service, were assured that the B.M.A. would, on our behalf, fight. What a fight! Unlike that great strategist Montgomery it would appear that the B.M.A. have a new technique—i.e., fight without weapons even though they be there for the handling.

At a meeting in Leicester Dr. Guy Dain informed us that the armoury was well stocked and all doctors would soon receive printed propaganda for distribution to their patients informing them of the views of the profession. We are still waiting. At this date only a minority of the public is informed on important details of the scheme, such as the fact that only 10d. of the forced levy per week is to be utilized for the medical services. With a little intelligent co-operation between the medical profession and the general public a powerful weapon could have been forged which would have ensured a successful new health scheme. The B.M.A. has failed completely in any attempt to bring the views of the medical profession to the forefront for examination by the general public.

All that is necessary for a new scheme to be acceptable to public and doctors alike is to include dependants of insured persons in a comprehensive scheme so that the working man would have the right to call in a doctor to his wife and family in a time of need without worry of bills to follow. Such a scheme would be acceptable to the profession and would necessitate no new officials or such a sweeping clearance of methods which have withstood the test of time. The scheme in its present form is a mass of inconsistencies and leaves the general practitioner with a sense of utter frustration.

Such matters as the supply of house and surgery for the use of an incoming practitioner to a new practice are apparently beneath the dignity of a Minister of Housing to consider, but when any change of practice is attempted this must cause complete confusion, since a practitioner may not sell his house and bricks and mortar. With regard to goodwill, under the present N.H.I. scheme a doctor takes his salary from the State, and he would want the goodwill of his practice—to whose detriment, I ask? Do two wrongs make a right? If it is wrong for a doctor to sell goodwill, how does it become right for the State to buy goodwill, lock, stock, and barrel?

I am at all times convinced that, if the B.M.A. were to put in an understandable form the conditions under

which doctors are being blackmailed into a service which majority thoroughly dislike, then the public would have opportunity of assessing the value of the services they are to obtain from a dissatisfied profession. It is the people are being called upon to pay for this new service, and have the right to know how their money is being spent, many consultations or bottles of medicine will the public see for the sixty-odd million pounds that Mr. Bevan proposes spend on buying the goodwill of doctors' practices? If it is all this money available to spend would it not be possible put it to better use than merely using it as a lever by a political party to keep doctors in their place—i.e., as employees of the State with no right to criticize their employers except at risk of dismissal?—I am, etc.,

Kibworth, Leicester.

RAYMOND F. SIMKIN.

National Health Service

SIR,—Two years ago the then Editor of the *Journal* refused a letter from me on the new Health Act as being likely to offend or prejudice. I made three points then—namely, (1) that the Minister of Health would not negotiate in the ordinary way expected of him, that he was determined to get his way, and on this account we should be prepared for a lengthy battle; (2) that we should use all and every method, even to strike (our ideas striking), to prevent the Minister getting away with it; (3) that from the highest officials and chiefs of Headquarters to the humblest practitioner we should try to get a promise of "no surrender" until we had a fair and square deal.

After two years of fruitless negotiations this letter of 1946 does not seem offensive to-day. I am appalled and grieved at the way the "sponge has been thrown in" in these last few weeks. Examining the position coolly and impartially, I was proud to stand the B.M.A. and ourselves were making up to the first plebiscite. Democratically we were informed of the situation and asked to vote "yes" or "no" on three or four important issues. We had the all before us—"no whole-time service," "right to buy and sell practices," "right of appeal," etc. The majority answered "No" to the lot, not to one vital principle alone. As was to be expected this was too much for Mr. Bevan and the Government, who let the wind up so badly as to stage a debate on an already passed Act, a most unusual and rare parliamentary procedure, and, in the form, the Minister's utterances were given full play. This debate, of course, had no object but to frighten us and affect the plebiscite. It failed to do either.

Now armed with the results, the B.M.A. Negotiating Committee had all the strength and weapons it wanted, and the Minister knew this well. Airily, in response to an arranged question, he told Parliament of his good will, and as some doctors did not agree to accept the Act as it was, if it was only a matter of not making us Civil Servants (as he had always promised not to), and if an Act of Parliament was a little more reliable than his word, he was willing to introduce it.

Next comes what to me staggers the intellect, that because of the crumb thrown by the Minister we are by the "considered" judgment of the Council asked to vote again. Why? Hadn't the Council already got their mandate? Did the fact that Mr. Bevan gave in in one particular answer for the other unsolved questions? Then consider the way this plebiscite was carried out. Voting papers were quickly sent out. A few days only were given to consider the questions. No information like the first plebiscite, but a slight innuendo that things were better and that we might now change our minds with honour if not with impunity. Thousands of men like myself did not vote, could see no reason in voting, and it did not require prophetic sense to see what the results would be.

The long and the short of it is that the second plebiscite, whether meant to or not, gave a loophole to (1) those who could not make up their minds before, (2) those who would work the Act anyway, no matter what the terms were (nothing to lose, something to gain), (3) certain sections of the profession to whom money and the quickest ways of making it are all-important, principles and ethics of little or no importance—in short, renegades and black sheep. I must omit from these lists, of course, many honourable and strict members who conscientiously thought the Act an improvement on the present health service, and always said so from the start.

Naturally then, when the result of the second plebiscite was known, defaulters made their mark, but even so the majority still refused service, and what is democracy but the majority rule? Still we are told that if we can't get less than a certain number, minority rule. Who fixed this 13,000, and even if 13,000 voted for the Bill, could the Minister work it with these 13,000? What need was there for a second plebiscite at all, except to spend money which was scarce some weeks ago? If the Minister conceded another principle might we then have a third plebiscite? Meanwhile he, the Minister,

CORRESPONDENCE

JUNE 5, 1948

sets out his medical cards to the public before any agreement has been reached with the doctors. A diabolical trick to confuse and force them to accept the Act. The resolutions of the Council ("considered judgment," when we all know there was only a small majority for resuming negotiations) under the first of which, while professing our altruism and magnanimity instead of our complete lack of spunk and courage, the profession is advised to work the concessions. After all that has happened, after all the machinery the B.M.A. had with the Ministry, is it likely once the machinery is set in motion on July 5 that Mr. Bevan will be more conciliatory?

What a betrayal! What a come-down! As I said in my letter two years ago, Mr. Bevan cares little really for the National Health Act. What he does care for is to imitate and emulate his illustrious countryman, Lloyd George (though I am afraid he will have to be reincarnated), and when we are all busy quiet gentlemen doing our work under the State he will hurry back to Wales and tell his excited audiences that he has beaten the doctors to smithereens, got them where Lloyd George never did, and *ipso facto* he is the greater statesman of the two. What is the ambition behind all the sneers and insults and annoyances to a profession which I am sure has never harmed a man but has always been ready to help the community and the country. There is still time. The R.B. can yet save us. It's now or never. We must cling to our professional liberties and, most important, the liberties of those who come after us. If not, any unpleasant epitaphs will be written and thoroughly deserved.—I am, etc.,
Walton-on-Thames Surrey.

Royal Colleges' Action

SIR.—The result of the latest plebiscite shows the profession nearly equally divided for and against the National Health Service. This contrast to our previous solidarity has been brought about to a large extent by three factors: (1) The action of the Council in turning down the Gateshead resolution without allowing a free vote of representatives; (2) the financial "sanctions" imposed by the Minister, who will not allow compensation to those joining the Service after the appointed day; (3) the attitude of the Presidents of the Royal Colleges, who quote Dr Basil S. Grant (May 1, p. 854) "failing to learn from the unhappy results of their previous intervention, have superseded the Negotiating Committee in its dealings with the Minister."

We cannot now do anything about points (1) and (2), but it does seem important to take steps to prevent further interference by the Royal Colleges in the important negotiations still to come. The profession are now in a much weaker position than previously, and it is imperative to get rid of this Trojan Horse whose presence has twice had such disastrous effects. I can only suggest a strongly worded resolution at the next S.R.M. pointing out that no matter how strongly these gentlemen favour the nationalization of medicine (after all, the N.H.S. is only part of the nationalization programme) they represent only a tiny fraction of the profession, and that any further pronouncements by them be ignored. In addition, representations might be made to the Colleges asking them not to take any further unilateral action in support of the Minister.—I am, etc.,
G. A. BAKER, WATERS

Lincoln

Postpone Service

SIR.—We are told that it will not be possible to introduce an Amending Act until next session. It is impossible to frame terms of service for consultants until the Spens Committee reports—not earlier than July. Surely there is only one sensible course. Let us offer to attend our present N.H.I. patients under the old terms for a further six months while negotiations are continued. If Mr. Bevan agrees, it would give time to straighten out difficulties. If he does not agree he would be doing a great disservice to the insured population, and the public would see it as such.—I am, etc.,
Birmingham

SIR.—We are mostly an inarticulate profession and leave letter-writing to the other man. However, that does not mean to say that we do not feel deeply how badly we have been let down

by our Council. I write to support those who are asking for postponement of service until a satisfactory Amending Act is on the Statute Book, and I feel certain that a vote on this point would show an overwhelming majority of the profession in favour of postponement. We must not go into this Service until we can do so as absolutely free men and women.—I am, etc.,
East Hove Surrey.

BASIL S. GRANT.

Hybrid Service

SIR.—It is not easy for those of us who cannot see behind the scenes to understand why, after such a long-continued expression of opinion against the conscription of doctors into a State service, the Council of the B.M.A. should suddenly advise doctors to join. Surely the Council realizes that nationalization will mean the end of British medicine as the world has known it? After a prolonged and tumultuous labour, a hybrid will emerge endowed with the characteristics of that parody of medicine the N.H.I. and the sterility of Service medicine. The true aspects of nationalization are being realized by the public now, and for the Government which at the present time is purloining for a national service which is a piece of political expediency a branch of the profession can give it a piece of political expediency. We frequently wonder how the peoples of great nations like the Russians, the Germans, and the Czechs have managed to do so. The past apparently willingly forsaken individual freedom for State serfdom, yet we Britons at the present time are not prepared to do anything which differs not in kind but only in degree. Many doctors who remained outside the B.M.A. because they have constantly disagreed with its policy must have joined to help in the fight for freedom. The deplorable action of the Council now calls for resignation. Mine has already been sent to the Secretary.—I am, etc.,
Guernsey

FRANK R. NELBERT

Medical Partnerships

SIR.—Apart from (1) direction of doctors by committee rule and (2) loss of many doctors' houses and surgeries to medical practice which the forbidding of the right of sale of the goodwill of practices and partnership shares will involve, two further drawbacks emerge:
(1) The partnership of work will not be practical where the senior partner requires help to ease his work in a so-called inadequately saturated area. A doctor who takes a partner will find him quickly purchased but will never work otherwise.
(2) Doctors will not be able to retire because, read, with the high rate of taxation few medical men can save for retirement, and after July 5, 1948, superannuation will not enable them to live in reasonable comfort, nor will a pension be sufficient for their wives, nor will the capital levy encourage anyone to save. Previous to this Act the practice and house could be sold and the sum obtained together with savings (the future superannuation) made a living possible when supplemented by fees from a few private patients. This source of supplementary income will cease when the comprehensive service commences.

Even Mr. Bevan's belated concession that "consent" for doctors to choose their own partners and assistants will be "automatic" becomes inoperative when conditions arise in which partnership is discouraged and undesired. It is obvious that there are two separate elements in the reasons for having and choosing a partner: the first is suitability of character, the second the business element. The profession has been given the concession of the first, but this is meaningless without the second, the element of introducing the partner by sale of share. Established doctors will select only a proportion of the doctors newly coming into practice, for whose entry the consent of the Central Practices Committee will be automatic, but the majority will still be directed by so-called "negative direction" and have to "squat" with a basic annual salary of £300 at the discretion of the three statutory committees whose decision will not be "automatic." This discrimination against the unselected is unfair.

There seems then to be an unanswerable case both for the public and the profession to press for independent medical practice. This can be achieved only by: (1) Retention of the right of sale of family practice (2) retention of the right of sale of partnership shares; (3) retention of the right of sale of goodwill.

W. MORISON.

(3) independent hospital service with independent administration and consultant service; (4) safeguards for those entering the State Service to prevent any political or other patronage from influencing appointments to hospital or family-doctor practice.

It is urged that doctors should not accept contract of service under this Act, either in the family-doctor or consultant service, until the Amending Act with its terms and conditions of service has been considered and accepted as workable by their representatives. This is not only on behalf of doctors and patients who are forced by economic pressure into the Service but also on behalf of those who are able to stay out of it. Doctors should negotiate as a whole for both groups.—I am, etc.,

London, W.1.

GEORGE ROSSDALE.

Avoid Confusion

SIR.—In 1946 a powerful Government gave promise that the profession's avowed object—efficient doctoring based on pathology rather than the purse of the patient—might be realized. Instead into the medical arena was precipitated an ignominious Act.

Our victorious forces brought back to the mother country an expectant spirit. The strategic move of the Ministry was to have captured its volunteers instead of coerced and diffident doctors. Such an enthusiastic, well-knit profession would have achieved wonders while the "men and the guns" were being doubled for a national health campaign. The existing machinery of the profession was good—"double the quantity" was the main need, to give us time for early diagnosis and easy admissions when hospital beds were needed. Good health guarantees good production too.

But it was not to be. The Act made havoc of our machinery, replacing it by promises which are empty and never could provide the standard of service that we require. Instead of restoring and raising the prestige of the family doctor, conditions under the Act will breed a race of medical prostitutes as the gap between precept and practice widens. This truth has dawned on the busy lives of doctors and made them uneasy accomplices in a shabby service. There is a hollow ring now about the words of exhortation by the Minister when introducing the Bill, bidding us "dedicate our lives to the tasks of peace."

Elementary prudence indicated that instead of getting Parliament to pass it over our heads the Minister should have sought from the profession which has to work it the basic plan of a new health organization. Hasty fanaticism is out of place where even in these days the "man in the street" would proceed with caution. This omission doomed the Act to failure.

1948 is here and confusion reigns in place of construction. The appointed day draws on and there will follow it the day of public retribution over a degraded service, unless the people are warned and retrieve the deplorable situation that threatens. It is never too late to avert disaster, but all the more imperative to do so when one of such magnitude as the national health is at stake. Why preach "Keep death off the roads" if you avoidably pile it up in hospitals? Let our public relations committee flood the country with emergency meetings telling the people that the Act does not accord with the interests of either the public or the profession. Implore them to write to their M.P.s to amend the Act according to this proposition: "Doctors are all overworked and medical reform can only proceed by stages, starting with regionalization of hospitals and extension of panel benefits to the whole family and dependants of the insured as an interim measure."—I am, etc.,

Bury.

A. WILFRID ADAMS.

Civil Servants

SIR.—One must respect what Dr. Alfred Cox (May 15, p. 949) says, but must also note the remarks of Dr. H. Simpson, P.R.O. to Bury Independent Committee (p. 950). The truth is that on July 6 doctors become unwilling Civil Servants, and we do know that the public will get what the New Zealand public has already got—unsatisfactory service. No doctor worthy of the name will accept a serious case, but economic blackmail

is the only way the Government can make a new Act and get it passed. They could not do this if good-

will had been retained. The Council's jubilation at a session undermined the last plebiscite. We at the time think we have been "sold out." The whole fight seems to have been in order to get a big majority in the February poll. Is that all we have striven for, with all the meetings, journeys? Why consider public opinion on a compromise like this? Many people do not want this insurance for them, but they have not been asked, and a similar applies to the question of capital punishment.

As Dr. J. McIntosh Rattray (p. 951) says, in giving up the nationalization of our souls we are betraying the entire cause. We had an opportunity granted to none others so far—State servitude.—I am, etc.,

Newquay, Cornwall.

J. P. O'NEILL

Regular Working Hours

SIR.—At this time when the hours of "workers" are so fully regulated to minimize fatigue and to allow for leisure is an opportunity and a justification to be rid of the ridiculous evening surgeries which have been so burdensome to the practitioner. Mr. Bevan has said that the National Health Service should be to the advantage of doctor and patient. Let us then insist most firmly upon hours which will allow a chance of relaxation and not accept times laid down by Executive Councils as we did under the old panel system, am, etc.,

London, W.1.

R. M. AYTON-ORMISTON

Policy for Peoples

SIR.—Your leading article on "Policy for Peoples" (May 15, p. 939) has an ominous ring. You state that the aims of P E P (Political and Economic Planning) are to increase the size of families and at the same time to widen the scope of contraceptive clinics. Just why the scope of contraceptive clinics should be widened if increase in size of families is encouraged is difficult to understand. One would have thought that all experience tended to the opposite view.

Then you say that P E P "expects a great deal from the National Health Service." Some of us who voted for the Bill did so in the faith that a British Government would always have a bias on the side of individual liberty. Yet you say that "in giving contraceptive advice generally doctors will help to foster the new attitude to parenthood without which a population policy based on democratic principles is bound to fail." Does this mean that doctors by their work would be expected to foster a Government policy, that is if the Government were to accept the advice of P E P?

Finally, you say that "there are individualists who maintain that no attempt should be made to influence people's reproductive behaviour." This naive statement might be more convincing if instead of the word "individualists" were substituted the word "individuals," for among the individuals concerned might be found the majority of the mothers and fathers of families in this country.—I am, etc.,

Braintree, Essex.

M. C. WILKINSON.

Otosclerosis

SIR.—It is not my desire to take up valuable space in your journal in order to prolong unduly an argument about otosclerosis, but I would like to place on record the conclusion which I and my colleague, Dr. J. Salomon-Danic, have drawn from a hundred fenestrations performed in the last 18 months.

First, it seems to me that the results should only be assessed after the lapse of at least a year; they seem to me to be roughly proportional to the value of pre-operative bony conduction, grouped according to Shambaugh's classification (a loss of 30 decibels in the 3 "conversational" frequencies—512, 1024, and 2048—dividing the cases into three classes, A, B, and C). Although this classification is imperfect, it seems to me to be worthy of retention, and in the evaluation of end-results it should play a part. Further, the improvement in bony and aerial conduction in the ear not operated upon, although very inconstant, is not a myth; a comparison of pre-operative and post-operative audiograms permits its recognition. Source had already drawn attention to it a long time ago. Up to 1947

Liver at meal times

Proteolysed Liver A&H is prepared by a process which eliminates the nauseating flavour of raw liver. Its palatability has been further improved by its presentation in a paste form. It may be readily incorporated in the normal diet by its inclusion in soups or on toast, bread or dry biscuits.

In pernicious anæmia and other megalocytic anæmias proteolysed liver has proved effective in cases which have failed to respond to extracts of liver in general use.

PROTEOLYSED

"Blackcurrant Juice in Modern Therapy"

The latest information on the therapeutic uses of natural vitamin C has been brought together in practical form within the covers of a handy 8-page booklet. Here is an extract from the contents:

- In Infancy and Childhood
- During Pregnancy and Lactation
- In Dental Conditions
- In Peptic Ulcer
- In Fractures and Wounds
- In Blood Dyscrasias and Haemorrhagic states
- In Infections
- In Skin Disorders
- In Fatigue
- In Other Conditions

A copy of the booklet will be gladly sent on application to Room 19, H. W. Carter & Co., Ltd., Bristol 2, makers of Ribena Blackcurrant Syrup.

A GREAT REPUTATION IS A GREAT RESPONSIBILITY

A reputation, once gained, can be maintained only by unceasing watchfulness. The fame of the Wellcome Insulin is due, not to chance, but to the maintenance of unflinching research and most rigid standards of manufacture. The discovery of Globin Insulin (with Zinc) and its introduction to the medical profession resulted from work carried out in The Wellcome Research Laboratories, Tuckahoe, New York.

Globin Insulin (with Zinc) fills the gap between the rapidly-acting unmodified insulin and the slower-acting protamine zinc insulin. Together, these three cover the whole field of insulin therapy.

'WELLCOME'

INSULIN Unmodified (with Zinc)
20, 40 and 80 units per dose in 5 and 10 cc bottles

GLOBIN INSULIN (with Zinc)
40 and 80 units per dose in 5 and 10 cc bottles

PROTAMINE ZINC INSULIN
40 and 80 units per dose in 5 and 10 cc bottles

PAIN ENDS...

Pain is almost always accompanied by nervous manifestations and often, too, by fever. Hence, pain suppression is usually only a part of the therapeutic task. Pain must not only be stopped but the associated nervousness must be calmed and an existing high temperature reduced to normal.

Veganin* is an efficient means of achieving these objectives. Because of its synergistic combination of acetylsalicylic acid, phenacetin and codeine, the effect of Veganin is rapid and prolonged. The patient experiences almost instantaneous relief from pain; the nervous irritability and fever quickly subside, preparing the way for rest and recuperation. If no fever exists, Veganin does not lower the temperature.

Composition: Each tablet, 11.8 grains, contains w/w: Acid Acetylsalicylic 32.63%, Phenacetin 32.63%, Codeine 0.99%, excipient, ad 100.00%.

Cutaneous Cancer

SIR.—Your leading article on the above subject (May 22, 1946) recalls an experience which may amuse your readers. In the early summer of 1937 the Bill which became subsequently the great Factory Act of 1937 was considered in Standing Committee. The Committee consisted of 70 Members of Parliament from all Parties, and for the greater part of its activities as the only medical Member. There were 27 sessions of the Committee. The Bill bristled with medical problems, and, being only Member with medical experience, I was a frequent speaker. Sir John Simon, as Home Secretary, was in charge of the Bill; my seat was directly behind his, and duologues between him and myself were constantly repeated. One of our most serious disagreements came over the schedule of industrial diseases subject to notification. The Bill was a consolidating Bill, superseding all previous Factory enactments, whose purpose and effect would be to legislate for a generation to come: the previous main Act was the 1901. In that Act a number of diseases had been scheduled as notifiable the incidence of which had materially diminished in 36 years, and other diseases had assumed greater importance. I pointed out that phosphorus poisoning, notifiable in 1901, had almost ceased to exist in 1937, but cutaneous cancer showed a sharp upward curve of frequency. I contended that phosphorus poisoning should be omitted from the notifiable schedule and cutaneous cancer included, notification of which would lead to earlier recognition and treatment and thus prevent the serious consequences which were frequent in many of the items as possible from the 1901 to the 1937 Schedule, and the Schedule of notifiable industrial diseases in the 1937 Act (*vide* Section 66) remains, as in 1901, restricted to lead, phosphorus, arsenical or mercurial poisoning, or "anthrax."—I am, etc.,
E. GRAHAM-LITTLE
House of Commons.

Risks of Dicoumarol Therapy

SIR.—In your annotation on the risks of dicoumarol therapy (May 22, p. 988) the work of Glueck and her colleagues¹ is quoted on combined heparin-dicoumarol therapy in coronary thrombosis, the results in a treated series of 44 patients compared with 44 controls being as follows:

Thrombo-embolic complications			
	Present	Absent	Total
Treated	3	41	44
Controls	12	32	44
Total	15	73	88
	Died	Recovered	Total
Treated	9	35	44
Controls	20	24	44
Total	29	59	88

It is then stated, "Though these figures may not satisfy statistical demands, it is only by the accumulation of the results of careful clinical studies that final decision will be reached on this important problem." Readers may be puzzled as to why significant differences are dismissed as not satisfying statistical demands, so it may be helpful to point out how the misconception has arisen, a misconception that is due to the authors of

the paper rather than to the writer of the annotation, for he has simply quoted their conclusions.

In the body of the original paper the data referred to 25 treated patients and 25 controls, and among these neither of the differences shown above, though favourable to the treated, is significant, as is pointed out in the conclusions. A short addendum is then appended giving results for a further 19 treated patients and 19 controls, observed after the manuscript had been submitted. The authors, however, do not point out in the addendum that with the addition of these new results the previous conclusion as to the statistical significance of the differences requires modification.

Both the tables shown above give $\chi^2 = 5.143$ (using Yates's correction). Thus in both instances the chance of drawing two such diverse samples from a homogeneous population is no more than 1 in 43, the usual conventional level of statistical significance being 1 in 20. The authors selected patients for the two series by the sound method of choosing alternate subjects for treatment. They remark in their conclusions (on the total of 50), "Although the series of cases is too small, and the variables of the disease itself too wide to make statistical analysis significant . . ." This might be taken to imply that even if the results were significant they would still be doubtful, owing to the variability of the disease, as to whether differences might not be due to some accident in the selection of alternate patients rather than to the results of treatment. They have, however, tested a considerable number of variables, and scrutiny of their tables shows (in the first 50 at least) that none could account for the more favourable experience in the treated group. If then detailed analysis of the 38 additional patients yields the same results as the original series, it would seem that a good, though not of course overwhelming, case had been made out for the beneficial results of anticoagulant therapy.—I am, etc.,
J. A. FRASER ROBERTS.

Peptic Ulceration

SIR.—I am very glad to hear Mr. C. Jennings Marshall's approval of the analogy between the pains of chronic peptic ulcer and of chronic ulcer of the leg (March 13, p. 523), but I am sorry that he is dissatisfied and has reservations, seen in his question. "Surely the production of pain in the peripheral nervous system has a mechanism different from that in the viscera?" Then again, it appears that he is dissatisfied with the secretory function as a middle term in the pain mechanism, so he selects the motor function. This is not very strong positive evidence in favour of his middle term and I am sure he is dissatisfied with this position also. He rightly indicates the mechanism no different from that in the visceral. There may be a quantitative difference because pain fibres are more sparse and less efficient in the viscera, but surely there is no essential difference.

Next, he insists that "food relationship of ulcer pain inevitably introduces gastric function as a middle term." Food relationship inevitably introduces gastric function, but not necessarily as a middle term. It only becomes necessary to introduce the awkward middle term if the stomach functions are conceived in terms of only a secretory and a motor system. But, if it be remembered that the stomach has in addition a functioning circulatory system, gastric function will be found already included in the first term. In the leg, the circulatory and circulatory changes directly explain the ulcerous cellulitis and directly painful motor behaviour of the leg.

A further advantage of these forward steps is that Mr. Jennings Marshall will find that his own favourite "most

potent cause," the ebb and flow of inflammation, will be found adequate to explain the symptoms without the interposition of direct motor causes. Moreover, he will no longer fear the Greeks, even when bearing a question about pain-relief from haemorrhage, for he will be able to discard "muscular atony from acute anaemia" as an unsatisfactory explanation, either in peptic ulcer or congestive dysmenorrhoea. Such prostration, as is implied, does not necessarily accompany pain-relief.

Finally, if he leaves out the myogenic middle term, he will not be called upon to explain how nebulous motor disturbances can directly cause pain in ulcer patients, while definite and violent motor disturbances fail to cause pain in obstructive or regurgitant vomiting after gastro-enterostomy, or in obstruction at the duodeno-jejunal flexure due to carcinoma. Nor will he be asked to explain why, in pyloric obstruction, "the very powerful peristaltic waves which can be seen through the abdominal wall are rarely accompanied by any discomfort" (Hurst and Stewart).—I am, etc.,

Sydney, Australia.

V. J. KINSELLA.

Acute Intussusception in Childhood

SIR,—I read the article on acute intussusception in childhood by Drs. Brenda Morrison and Donald Court (April 24, p. 776) and letters in subsequent issues. The authors of the article state that it is very difficult to satisfactorily examine a healthy baby. With this I cordially agree, and it is particularly difficult during the contractions of the intussusception (when it is hard and most palpable) because then the baby yells most lustily. It is at this stage that, barring accidents, 100% of the babies should be saved.

There is only one way by which one can make absolutely certain that an intussusception is or is not present—that is by a bimanual exploration with the right forefinger in the rectum, under anaesthesia. Quite light anaesthesia is sufficient and chloroform the best anaesthetic. If the case is in hospital the child can be examined in the theatre and either the abdomen opened or the surgeon retire with a perfectly easy mind. The authors of the article and subsequent correspondents make no mention of this method. By carrying it out one can explore every part of the abdomen in a child under 2 years.—I am, etc.,

Great Yarmouth

LEONARD LEY.

SIR,—May I add a further point to Drs. Brenda Morrison and Donald Court's timely article (April 24, p. 776) calling for earlier diagnosis in acute intussusception in children? Under the heading "Signs in the Abdomen" insufficient stress is given to palpation of the abdomen. In the initial stage of the condition, and before obstruction and peritonitis have occurred, the mass is only palpable during active peristalsis, and it may be necessary to palpate the abdomen several times before a clear and unmistakable cylindrical tumour is felt. Usually colic occurs at that instant, but it may not be severe. Only by repeated palpation in the early stages, when vomiting and flexion of the thighs or the abdomen are the presenting signs, will the initial and pre-inflammatory stage of intussusception be diagnosed.

Mention is made in the article to the similarity in description in most British textbooks, and I would refer the authors of the article to that given in the 4th and 5th editions of the textbook on paediatrics published by Messrs. E. and S. Livingstone.—I am, etc.,

London, W.1

BRUCE WILLIAMSON.

Pain in Phantom Limbs

SIR,—I was very interested in Dr. J. Donaldson Craig's letter (May 8, p. 904) on "Pain in Phantom Limbs." The subject of painful stumps is a difficult one. As a medical student I do not remember a single instance of my teachers telling me anything about the subject; and as to the question of phantom limb, the paucity of the literature concerning this distressing condition speaks for itself. Space does not permit of my dealing with painful stumps and I will therefore only briefly discuss the question of phantom limbs.

In the intact body there is a continuous stream of impulses bombarding the brain from the sensory nerve endings in the muscles of

the body. This bombardment is evenly balanced on both in a state of equilibrium. When a limb is amputated muscular imbalance immediately results (see diagram), play a great part in future motor activity of the individual influence his phantom limb.

It is the readjustment of the remaining muscles of the altered state which now throws additional strain on the cerebrum and makes the previously existing state of equilibrium so liable to be upset. It is the constant effort of the central activity to maintain this equilibrium between the continuous stream of impulses from the remaining part of the body which makes a phantom limb an ever-present possibility and brings the awareness of the absent member to consciousness.

The capacity of the individual's sensorium to readjust itself to the new conditions of his body and its new environment after an amputation may or may not give rise to the varied manifestations of a phantom limb. The physical alterations and mental fluctuations in his subsequent life will act as stimuli and as predisposing factors to cause a central release which will result in pain in the phantom. All amputations are associated in the mind of the individual with a varying degree of pain. This is not dependent on whether pain has preceded the amputation. Further, the individual will react to this pain according to the degree of subconscious pain which already exists in his sensorium, and this phantom pain will be further modified according to his level in the phylogenetic scale. It has been noticed that highly intelligent, sensitive patients are more prone to phantom pain than the more phlegmatic, unimaginative individuals.

It has been observed that wearing an artificial limb is often a comfort to the patient with a phantom pain, and tight bandaging, at night, when his phantom pain becomes aggravated, relieves this pain. In fact, many individuals often hold on firmly to their stumps with both hands in order to relieve the pain. This pressure has the effect of restoring temporarily the balance of the impulses which impinge on the sensorium and so relieves the pain. These observations influence treatment. The patient himself often doubts the reality of his own sensations. Fear of accusation of insanity makes him reticent to talk about his symptoms and he prefers to hide them until he can no longer bear them. This may result in gross mental disturbance, and the sufferer of a phantom limb is often regarded as psychotic.

The patient who shows the slightest indication of phantom pains should be told that we believe he gets these pains—that they are very real to him; and, since he has lost his limb, from his point of view there is no foundation for the stimulus now. Eventually the pains will cease, which indeed they often do.

I agree with the statements that all the operative measures of these conditions usually fail, and I would like to point out that local injections are of very fleeting value. A simple and effective method of treatment by firm bandaging of the stump bears out the hypothesis which I have postulated above: "Sensation removed by amputation must be replaced by further sensation." I would further like to say that phantom limbs are not analogous to causalgia. Amputations of the fingers are not infrequently accompanied by causalgic pains, while phantom pains are rare in fingers because there has been no loss of bulk stimulus. Causalgic pains are not relieved by pressure: phantom pains are.—I am, etc.,

Queen Mary's Hospital, Roehampton,
London, S.W.15.

LEON GILLIS.

Diagram showing (a) balance produced by amputation, and (b) normal state of equilibrium.

2.—May I add a few notes to the reply to the inquiry concerning pain in phantom foot ("Any Questions?" April 24, 1947)? French statistics show that 72.5% of all amputees, at least, complain of pains, most of them being phantom pains (personal statistics).

In 1938 I established that such pains are greatly relieved by parenteral thiamine in a very high proportion of cases. In this quite easy method fails to give relief we perform a sympathetic ganglia "novocain" block or a periarterial injection of novocain. Intra-arterial administration of the drug sometimes relieves the pain immediately and suppresses the phantom limb sensations. At the next stage we proceed with barbiturate or cervical sympathectomy, advisable in cases in which block gives only transitory relief. The surgical treatment by the main sensitivity route (excision of the terminal neuroma, sympathectomy, cordotomy) is performed in cases of failure of the above-mentioned more conservative methods. Recently some authors claimed the success of excision of the nerve, but their trials seem to remain merely in an experimental stage. Lately, psychotherapy has been introduced in the treatment of this very refractory condition.—I am, etc.,

A. SLOSBERG,
Consulting Physician of the Fédération
des Amputés de Guerre de France.

Tetanus Neonatorum

SIR.—The two cases of tetanus neonatorum recorded by Drs. A. St. Hill and H. Lederer (May 22, p. 980) lead me to report the following:

On May 14, 1948, there came to my clinic a young man, aged 21, complaining of pain in the front of the left thigh which had been present from infancy; he said he rarely went a week without it. He had been called up at 18 for military service and had been awarded A1 and served his full time. He was accompanied by his father, who told me that he had been under my care in the Lincoln County Hospital when aged 12 days, with tetanus. I immediately remembered the case, for it was most remarkable. I looked up the notes, but unfortunately they were scanty. He was born at full term, and breast fed until 7 days old, when his mother was "locked" and he could not suck; he had had nothing to eat for 5 days prior to admission. Temperature was 104° F (40° C.). He was wasted and profoundly dehydrated. Every muscle was in extreme tonic spasm, and the legs were crossed in extension. He could be held in any position, the head, back, and limbs being perfectly rigid. Placed on the palm of one's hand he was as like a piece of board. He remained in this condition for about three weeks and then began to recover, often having appeared on the point of death. The stump of the cord was septic as well as the prepucium. He was fed by nasal tube and later with a dropper. 100 units of A.T.S. were given intrathecally. The C.S.F. was clear and not under pressure.

On May 14, 1948, he appeared a healthy young man with a lightly waddling gait. He was working as an apprentice electrician. My examination revealed nothing to account for the pain; in particular his C.N.S. was not abnormal. I referred him to my colleague, Mr. E. J. Bilcliffe, orthopaedic surgeon, and he reports as follows: "Marked loss of power in his left quadriceps, and can barely hold his leg from the couch; some limitation of movement of left hip." X rays of both hips show marked coxa vara, with considerable shortening of necks of both femora and very shallow acetabula. The coxa vara on the left side is more pronounced than on the right. Is the tetanus a factor in the cause of the condition?—I am, etc.,

H. CECIL BARLOW.

Lincoln.

Inserting Needle for Local Analgesia in Dentistry

SIR.—To minimize the pain of inserting the needle into the gums we have a number of analgesics for surface application at our disposal, but we cannot depend on surface application alone because of its insufficient penetration, and the technique of inserting the needle has to be added. Already in my time as assistant it was my aim to make the dreaded insertion of the needle as humane as possible. Guided by this principle, I soon found that only the insertion of the needle at absolute right-angles to the injection surface brought favourable results. The reason for this is that the skin remains in its place and not stretched away by the pull or pressure of the needle. By injection

for extractions of teeth, although it may not always be possible to place the needle in at right-angles, one can follow the described principle as far as it is possible.

This process—with the exception of palatal injection—is done in three phases. The first phase is the short and quiet insertion of the sharp needle into the skin. The second phase consists in bringing the needle almost into line with the skin. During the third phase the needle is by constant flow of analgesic brought slowly to the position where the injection fluid is to be discharged. All injections which are easily accessible can be done according to the described three-phase system from "vestibulum oris" with the mouth not being much opened. According to requirements the teeth can also be completely closed. Awkwardly accessible are the injections in the lower jaw from "cavum oris." One is here compelled to follow the described principle as much as possible.

For the extraction of the lower molars the "endosteal" injection method is more to be recommended, and I refer here to my publication "Das endosteale Injektionsverfahren zur Extraktion unterer Molaren." in *Schmerz-Narkose-Anästhesie*, Leipzig, 1937, vol. 1, and *Folia Stomatologica* (Zagreb), 1939, Part 1.

Before writing down these small points about the injection technique in the sphere of dentistry, the thought came spontaneously to me that any pain-reducing measures, however small, should be made available to the practitioner. The fact that on the publication of my article on the same theme in 1943 in the organ of the Bulgarian Odontological Federation, Sofia, the editor of the *Zahndärztliche Rundschau* Sofia, made a footnote of appreciation expressing his pleasure in printing this work, shows for me that I followed the correct course.—I am, etc.,

JOHN VANDEN

The Problem of Caries

SIR.—Mr. J. F. Volker (May 22, p. 1000) suggests that the most unsatisfactory aspect of dental caries research is unscientific criticism by medical colleagues and explains this attitude as resistance to new ideas. This seems a superficial view of the unsatisfactory state of medical knowledge and opinion.

First, there is nothing new in the idea that caries is the result of acid fermentation of food residues, and that sugar is especially responsible has been recognized for centuries. Recent dental research has not done much more than slowly accumulate piecemeal experimental evidence of what was already obvious from general observations of diet and dental disease.

Secondly, the problem of caries is not its histopathology, which is now fairly well understood, but the practical and sociological problem of its prevention. Doctors, in Britain at least, have done as much to solve this problem as dentists. The names of Drs. Harry Campbell, James Wheatley, and R. A. Lyster come to mind, and of course Dr. J. Sim Wallace, who is a dentist as well. How can doctors, without formal training in dental pathology, be expected to appraise adequately the voluminous and confusing literature on dental disease? A great part of this is itself unscientific and some of it is frankly antiscientific.

The medical profession might be blamed for completely handing over to dental surgeons responsibility for dental health, instead of merely delegating dental surgery to them. The dental profession, having gained independence, is much more to be blamed for failing to inform the medical profession and the public in a coherent way how dental disease should be prevented. Volker mentions the repeated experimental proof that fluoride applications reduce caries by 40% in American children. English dentists are simply incredulous; they scarcely seem to distinguish between this completely substantiated claim and the vague, exaggerated, or unsubstantiated claims made for vitamin D, calcium, or humus-grown vegetables! Whose fault is this? Surely not our medical colleagues?

While research has shown that the defects of modern diet which are responsible for caries are not, in the main, nutritional deficiencies, yet the country's diet is planned for health on purely nutritional considerations. The B.M.A. has appointed a nutrition committee: could it not invite the B.D.A. to assist it with an authoritative statement on the dietetic prevention of dental disease? Collaboration of this sort in the U.S.A. has been very fruitful.—I am, etc.,

London, N.W.6.

R. B. D. STOCKER.

Curare in Treatment of Spastic Conditions

SIR.—Dr. Edward B. Schlesinger (May 8, p. 905) queries the potency of the curare in oil used in the treatment of our spastic cases. Only two preparations were available to us, that supplied by Messrs. Burroughs, Wellcome and Co., and that by Messrs. E. R. Squibb and Sons ("intocostin"). After a trial of both we preferred the former as it appears to give more uniform results. Of its potency there can be little doubt judged by the production of diplopia, a feeling of drunkenness, and ataxia in many cases.

The experiment was an attempt to determine the clinical value of the drug in cases with pyramidal spasticity (hypertonus). We think that the evidence of patients in such conditions is of more value than the myogram and motion pictures, for such a drug is of no practicable value unless the patient is improved so that he can appreciate the improvement.

We note with interest that Dr. Schlesinger in his detailed report of four cases (*Arch. Neurol. Psychiat., Chicago*, 55, 530) refers to subjective improvement and "perceptible decrease in spasticity" without mentioning the myogram, the range of motion changes, or other data "gleaned from the skills of the physiotherapist and neurologist."—We are, etc.,

The Mystery of the Eosinophil

SIR.—With reference to the interesting leading article on eosinophilic mysteries (May 15, p. 938), most common causes are mentioned, with one exception. Later it is stated that eosinophilic pleural effusions are common but unexplained. Surely tuberculosis is a common cause of eosinophilia in the blood, and also the cause of the unexplained eosinophilic pleural effusions? There is a well-known paper by Dr. L. S. Fry on eosinophilia in tuberculosis. Perhaps the learned writer was just trailing his coat here to invite discussion.—I am, etc.,

FELING, Essex.

FRANK MARSH.

SIR—Completeness is too much to hope for in reviewing within the space of a leading article (May 15, p. 938) such a complicated subject as eosinophilia. I was disappointed, however, that you did not mention familial eosinophilia, a rare but well-established condition.

Histamine may well be the "missing link" which connects together the various conditions in which eosinophilia is commonly found. In nearly all of them there is evidence of protein disintegration and allergy with consequent excessive production or liberation of histamine.¹ This substance is found in appreciable quantities in the granular cells, and especially in the eosinophilic cells.² The blood in eosinophil leukaemia contains a large excess of histamine.

My only attempt to verify this hypothesis has been unsuccessful. "Benadryl" and "anthisan" did not produce any consistent changes in the peripheral blood in a small number of cases of eosinophilia of various origin. This crude test, however, is not conclusive in either way.

The hypothesis has the attractiveness of simplicity, but, as always in science, facts must have the last say. Further research is needed, and I hope this letter will stimulate it.—I am, etc.

Harrison's Grooves

SIR.—Dr. J. Naish and H. R. E. Wallis (March 20, p. 541) have doubtless made a very useful contribution on the matter of the serratus magnus as you say. However, they should take more notice of its anatomy. I quote from their article: "The serratus magnus interdigitate most intimately with the fibres of the external and internal oblique muscles. Moreover, the serratus magnus runs diagonally across the thorax."—Harrison's grooves.

The insertion of serratus magnus is, in fact, into the lower border of the scapula. The lowest three or four slips of serratus magnus do indeed interdigitate with the oblique muscle of the abdomen; but serratus magnus interdigitate with the internal oblique muscle, intimately, otherwise.—I am, etc.,

Melbourne.

ROBERT S. LAWSE

Termination of Pregnancy

SIR.—A recent trial served to draw attention to the legal aspects of termination of pregnancy on psychological grounds. This is a comparatively new concept in both medical and law and one which, from its very nature, abounds in difficulties. Whether the grounds are physical or psychological it is essential to consider the woman as a total person against her own personal background and that of the contemporary world. If she is married the marital relationship and husband's attitude are vital considerations. Of equal importance is the question of whether or not the woman wants the child, since, obviously, if she does not, the prognosis is less favourable.

In addition to these general considerations others apply to psychological cases and present peculiar difficulties. When psychological grounds are presented we can usually verify the patient's condition and make a reasonably certain prognosis of the effect of pregnancy. In psychological cases, however, we are dealing with many factors and to a considerable extent unpredictable elements. Even with far greater knowledge than we have, we should still be handicapped by the difficulty of applying objective tests to the mind in general and the fact that each individual mind is unique and that reaction to a given set of circumstances cannot be prognosticated with an equal degree of certainty. It is essential to obtain confirmation of the history which patients give in psychological cases since the picture which they present will inevitably be coloured by their highly emotional state.

Perhaps the greatest difficulty, and one which seems all too often to be overlooked, is the psychological trauma—the profound and lasting feelings of guilt and remorse—which can result from termination of pregnancy. Even when continuance of the pregnancy would be inadvisable from every point of view, the psychological effects of termination might prove far more disastrous. In other words, termination is not the simple solution that it may appear to be on the surface. The choice between termination and continuance of pregnancy is rarely, if ever, one between good and evil, it is practically always one between a greater and a lesser evil. The determination of the lesser evil can never be certain. Nor are there any easy compromise solutions.

Perhaps the most common advice given to single girls is for them to have their babies and offer them for adoption. This may seem the only solution, but in fact it is rarely a satisfactory one. While escaping the stigma of unmarried motherhood, many of them will be haunted all their lives by guilt and remorse, especially if, as nearly always happens, they are allowed to see their babies and even persuaded to nurse them before adoption.

However much experience may lie behind our decision to terminate or to recommend the continuance of a pregnancy on psychological grounds, we can never be certain of the result. I personally terminated two pregnancies and recommended the continuance of one to preserve the women's health, only to find that in all three cases their entry into mental institutions had been hastened. The more experience we acquire in this sphere, the more we realize the difficulty of assessing a case, with its tragic result that at our present stage of knowledge and experience many pregnancies are terminated which should be continued and many continued which should be terminated.—I am, etc.,

London, W.1.

EUSTACE CHESSEB.

Barbiturates in Acute Porphyria

SIR.—Dr. Ernest Petrie (May 15, p. 926) describes a case of acute porphyria which shows many of the usual signs and symptoms of the disease. It is commonly stated, though so far as I am aware with insufficient evidence, that barbiturates may increase the severity of an attack, or even initiate one. Neither of these misfortunes befell Dr. Petrie's case, in spite of his patient having received phenobarbitone in the course of treatment. Discombe and I¹ described a somewhat similar case, and we were fortunate to be able to follow the progress of the

Athlete's Foot

Despite the implication in the name, athlete's foot is more prevalent amongst the spectators than it is amongst professional athletes, to all of whom care of the feet is of primary importance. The introduction of Mycil, the new fungicide—*p*-chlorophenyl- α -glycerol ether—developed in the B.D.H. Research Department, has made available to medical men a highly effective preparation for prevention and treatment of this wide-spread infection. Mycil is available as Mycil Ointment and Mycil Dusting Powder.

INTRAVENOUS ANAESTHESIA

with

'KEMITHAL' SODIUM

'Kemithal' Sodium (sodium cyclohexenyl-allyl-thiobarbiturate) is a new ultra-short-acting intravenous anaesthetic, evolved in the I.C.I. Research Laboratories.

In extensive clinical trials, 'Kemithal' Sodium has proved to be a highly efficient and satisfactory agent for basal hypnosis and for surgical anaesthesia of short or prolonged duration.

Having a relatively high therapeutic quotient, 'Kemithal' Sodium effects anaesthesia without undue respiratory depression. A number of workers have commented upon the reduced incidence of laryngeal spasm with 'Kemithal' Sodium.

Literature on request.

'Kemithal' Sodium is issued in ampoules of 1 gramme and 2 grammes in boxes of 5 and 25, with or without sterile distilled water in ampoules of 10 c.c. and 20 c.c. respectively; ampoules of 5 grammes 'Kemithal' Sodium are also available in boxes of 5.

EX-SURGEON LIEUTENANT. R.N.V.R.

Manipulation in a State Service

Manipulation in a State Service

SIR,—May I take this rather late opportunity to refer to Dr. J. H. Cyriax's letter (Feb. 21, p. 362) entitled "Manipulation in a State Service"? The importance of this neglected form of therapy has been stressed in some quarters through the years, but has apparently passed unheeded as far as the average practitioner is concerned. Manipulation is still shrouded in mystery and those who practise it are still regarded with suspicion.

As long as manipulation is not taught, and taught expertly, and those whose manipulation is of therapy remain in unorthodox areas, so long as a valuable field of therapy, many catastrophes occur unnecessarily, which must be taught and prevented.

So long will a valuable field of therapy remain in the hands and so long, quite unnecessarily, will catastrophes occur with its use. But, Sir, it is the doctor who must be taught and not the physiotherapists alone, as Dr. Cyriax recommends. The correct use of manipulation is the doctor's duty. It is the doctor's duty on diagnosis, and this is the manipulation and how far his manipulation also to know when to manipulate and how far to maintain the range of movement which the doctor restores and not to try to improve on it, for anything that may go wrong—and even in the most experienced hands things do go wrong—is the responsibility of the doctor.—I am, etc..

Criticism in Colonial Medical Service

Criticism in Colonial Medical Service

SIR,—I am forwarding the following to you as I feel it may be of interest to those engaged in the struggle over the Health Service and freedom of criticism of this service. It is from a Colonial Office circular about an essay competition organized by the National Association for the Prevention of Tuberculosis, and shows, I think, the fear of criticism existing in the minds of Ministers and higher officials of any Government service.

Like many others, I joined the Colonial Service after this high hopes, but already I am sadly disillusioned.

—I matter—this is immense—but by the treatment. Drugs and dressings are unbelievable.

Like many others, I joined the Colonial Association for the last war full of high hopes, but already I am disappointed not by the lack of clinical matter—this is immense—but by the lack of facilities for diagnosis and treatment. The lack of facilities for the medical stores in an unbelievably parsimonious way. I have not even a blood-counting apparatus, and such things as vitamin concentrates—almost essential with every patient here—are practically unobtainable. When I have ventured to ask for such things I am informed that they are not stocked. Anyway, here is the extract for you. It is from Circular 12412/12 '48 from the Colonial Office, the Church House, Great Smith Street, London. S.W.1. and appears over the signature of A. Creech-Jones.

Para. 3, Rule 8 [of the essay competition] provides that essays sent in shall become the property of the National Association for the Prevention of Tuberculosis and that any of them may be published at its discretion in the author's name. In order to ensure that nothing is published which might misrepresent the policy of Colonial Governments or of His Majesty's Government, the Secretary-General of the Association has agreed to arrange that essays which it is desired to publish should first be submitted to the Colonial Office, and in view of this I do not expect that you will think it necessary to require competitors to send in their essays through the heads of their Departments. However, I would not object to your imposing this requirement if you thought it desirable.

Must the Doctor Tell?

Must the Doctor Tell?

SIR.—The frivolous and irresponsible attitude revealed in recent letters from R.A.F. medical officers (April 17, p. 750, and May 8, p. 907) on V.D. probably shocked numerous others with Service experience apart from myself. Clearly, it is necessary in a disciplined service that a commanding officer should be acquainted with all facts concerning the welfare and efficiency of his men. If medical officers arrogate to themselves the decision to keep V.D. secret, they are simply not doing their duty. Such middle-headedness is nothing to be proud of, nor does it imply a high ethical standard professionally.

Such middle-headedness is nothing to be proud of, nor does it imply a high ethical standard professionally. Such middle-headedness is nothing to be proud of, nor does it imply a high ethical standard professionally.

acquainted with the R.A.F. and his men. If medical officers are supposed to keep V.D. secret, they are simply being muddle-headed. Such muddle-headedness is nothing to be proud of. It implies a high ethical standard professionally. In recent years the Air Council have from time to time expressed concern at the standard of discipline in the R.A.F. Your correspondents' impunity would seem to corroborate this. "Flight Lieutenant" was right in at least this point when he wrote, "Of course we should have been court-martialled . . .". I am, etc.,

GEORGE G. SHERRIFF.

London. W 8

GEOFFREY G. SHERRIFF.

POINTS FROM LETTERS

Direction and Right of Appeal
H. SHAW (St. Mawes, minor matter)

POINTS FROM

Direction and Right of Appeal

Dr. B. H. SHAW (St. Mawes, Cornwall) writes: . . . Compromise is all very well on minor matters, but direction and absolutism is co-part of the Minister are very grave issues as far as freedom is concerned. Are we or are we not to remain free from bureaucratic interference in discharge of our professional duties? That is the crux. Dr. Cox considers that the best way to prevent the Labour party from carrying out their declared intention at some future time would be "to use the interval for providing such a satisfactory service that the public would be against any attempt to unsettle the profession once more." It is not sufficiently realized that there is a very considerable difference between the views of the public and the ambitions of bureaucracy. The granting of the right of appeal is essential.

Agreed

(Chickenhead) writes: It is now well over 10 years since the Medical Councils by stating that the public interest would be served by the deterioration of the profession.

A Plea for the Aged

A Plea for the Aged

Dr. D. J. GAIR JOHNSTON (Birkenhead) writes: It is now well over a year since I startled my fellow councillors by stating that the general fitness and stamina of the people were definitely deteriorating. . . . The knowledge of nutrition in all its phases—digestion, absorption, assimilation, and elimination—is far from complete and allows no room for dogmatism. The question of getting sufficient nourishment of a kind suitable and agreeable to old people whose physical and digestive powers are failing is a real problem and, if they live alone, truly pathetic. . . . As a medical officer to a Home for Aged (about 180 inmates) for 25 years, I notice the dead hand of deprivations and restrictions has caused a very obvious depression. No smiles, no light-heartedness—just a dead monotony of gloom compared to other days. If those in authority would only realize that human beings are really human, not mere animals to be fed on calories, it would help to bring back a little of that light-heartedness and joy which is so lacking to-day in all classes of society.

Obituary

SIR GEORGE NEWMAN, G.B.E., K.C.B.

Former Chief Medical Officer, Board of Education and Ministry of Health

We announce with regret the death on May 26 at the age of 77 of Sir George Newman, who held for twenty-eight years the position of Chief Medical Officer of the Board of Education. Sir George Newman was also Chief Medical Officer of the Ministry of Health from the time of its creation in 1919 until his retirement in 1935. His service at Whitehall covered the period of the rise and growth of the school medical service and saw the initiation of some of the outstanding developments in public health.

(Press Portrait Bureau)

George Newman, the son of Henry Stanley Newman, of Leominster, Herefordshire, came of Quaker stock. He was born on Oct. 23, 1870, and studied for his profession at Edinburgh University and at King's College, London. He graduated M.B., C.M. in 1892, and took the M.D. of Edinburgh, with the gold medal, in 1895. In the same year he took the Cambridge D.P.H. From 1896 to 1900 he held the post of senior demonstrator of bacteriology and lecturer on infectious diseases at King's College, of which he was later to become Fellow. By the early

years of the present century he was already known as a writer on public health subjects, having published works on the bacteriology of milk, on the relation of bacteriology to public health, and on infant mortality. Dr. Newman's first experience as a medical officer of health was in the county of Bedfordshire; afterwards he was appointed medical officer to the metropolitan borough of Finsbury. In all these spheres—teaching, authorship, and administration—he showed evidence of unusual ability and was plainly marked out for a high position in the Civil Service. When in 1907, the year in which the system of medical inspection and physical care of school-children was introduced, his appointment as Chief Medical Officer to the Board of Education was announced it was generally felt that the new school medical service could not have a better official head.

This was a period of new beginnings. The Education (Administrative Provisions) Act of 1907 made it the duty of local education authorities to provide for the medical care of school-children, and this was followed by the Mental Deficiency Act and the Act providing for the care of epileptic and other defective children. The National Health Insurance system, which was introduced in 1912, had its indirect effect on the health of the school-child, and there followed developments in the field of maternity and child welfare, the dental service, Poor Law administration, hospital provision and usage, and public health services in general. The war of 1914-18 gave a new impetus to preventive medicine, and the idea of a Ministry of Health to co-ordinate all health work, including maternity services, and to provide guidance and inspiration to local authorities, appeared on the legislative horizon. Meanwhile on Feb. 14, 1919, Dr. Addison, as he was then, President of the Local Government Board, appointed Sir George Newman as Chief Medical Officer of the Board. It was understood that he would retain his position under the Board of Education and that the arrangement marked a further step towards the unification of the public health services which was to be one of the principal objects of the forthcoming Ministry. The post was a new one, and the holder was to have the status of a member of the Board as well as administrative responsibility for the work of his department. The Ministry of

Health was established under the Act passed in 1918. Dr. Addison was appointed Minister in June of that year, the Ministry took over the functions which had previously fallen to the lot of the Local Government Board and National Health Insurance Commissions. That great administrator Sir Robert Morant became its Secretary and Sir George Newman its Chief Medical Officer.

While it would be wide of the mark to say that Newman was the instigator of all the various health reforms which preceded and followed the establishment of the Ministry of Health, his genius made itself evident in many directions. Perhaps his mind was interpretative rather than creative. He had an unusual power of awakening public interest in health matters. He was in fact the perfect medical publicist, and he became more than any other man of his time to make the English people "health-conscious." He had, too, a real enthusiasm for increased knowledge on health matters and a determination to make people understand the facts. Entering the Civil Service at as late an age as 37, Sir George Newman never quite accommodated himself to its practice and traditions, which, with all their virtues and limitations, have meant so much to the country. He was always the medical man rather than the Civil Servant, and the health propagandist above all. If never fitted into the cadres of Whitehall, his passion for science, his high ideals of citizenship, his alert mind, his ability both to inform those whom he addressed and to move their hearts were of the greatest value to the nation, especially at a time when public opinion was focused on the "common health," to use the form of toast to which he once responded in a noteworthy speech at a British Medical Association dinner.

Sir George Newman's role as the official head of the health services was as often persuasive as administrative. Many examples of his wise guidance could be cited. One that immediately comes to mind is the list which he issued of the methods of prevention of rheumatism in childhood, a subject that always deeply interested him. A residential school of recovery for rheumatic children, which he first recommended to the Board of Education, was later declared by a special committee of the British Medical Association to be a necessity for every town.

The brilliant series of annual reports issued by Sir George Newman, first as an officer of the Board of Education and later as an officer also of the Ministry of Health, are his abiding memorial. These reports extend from 1908 to 1935. To many secretaries and others the compilation of an annual report is casually undertaken as a sort of appendix to the year's work, but to Newman it was much more. His reports were not merely a record of past or a forecast of future achievement, they were intended to be a kind of serial scripture for those engaged locally in the administration of public health. They had inspirational value, probing into causes as well as describing results, urging ideals as well as advising on methods. To a large extent they were from his own pen. Some parts of them dealing with special subjects were the work of his colleagues, but one could usually detect his own writing from its literary style, and from something more than style, from the warm glow of evangelistic fervour which informed it.

Over and over again in those reports Sir George Newman as the head of the preventive medical services of the country paid tribute to the work of the private practitioner as a pioneer in preventive medicine. In his official position he never failed to appreciate the importance of the family doctor's contribution. He realized that it was upon the general practitioner that the safeguarding of the public health depends, and that it is possible for health departments, both central and local, either to alienate practitioners or to enlist their whole-hearted service. In an annual oration to the Hunterian Society he strongly rebutted the view that the public medical services are designed to exclude the private practitioner. The contrary, he said, was in fact the case, and he pointed to the Poor Law medical service, which had 4,000 medical officers for outdoor medical relief practically all of whom were general practitioners.

Apart from the heavy and constant work which attended his double office Sir George Newman undertook many other important labours. During the war of 1914-18 he was chairman of the Health of Munition Workers Committee, a body which still lives on in the form of the Industrial Health Research Board. Another war activity of his was that of

OBITUARY

ical member of the Central Control Board (Liquor Traffic). Many interdepartmental and other committees of which he was a member were concerned with such subjects as play-grounds, reformatories, tuberculosis, medical research, the production and distribution of milk, the registration of dentists, and graduate medical education, and maternal mortality. He was in 1919 until 1939 Crown Nominee on the General Medical Council, and during the latter part of that time served the Council as Senior Treasurer. Medical education was one of his great interests and the theme of many of his public speeches. He was also medical assessor to the University Grants Committee.

In later years, as became a respected senior and wise counsellor, Sir George Newman was often invited to the lecture platform, a position which he valued and in which he always gave his best. He was often eloquent in speech and had the power of assembling facts and arguments in an attractive way, though a certain shrillness of voice when he became animated took away a little from the pleasure of his utterance. He gave Yale lectures in 1927, taking as his subject "Citizenship and the Survival of Civilization." He was Linacre Lecturer in 1928, Gresham Lecturer in 1929, Halley and Social Evolution, 1930, when his subject was "Health and Social Evolution," and Heath Clark Lecturer in 1931. The same elevated diction which characterized his orations appears in his published works in addition to the books already mentioned there appeared in 1919 his *Outline of the Practice of Preventive Medicine*, and in 1927 *Interpretations of Nature*. This last work includes some choice essays in which he indulged his love of the history of learning and of medicine. One of them, which he dedicated to St. Bartholomew's, justifies his veneration for the ancient University of Padua. Another is on Thomas Sydenham on the occasion of his bicentenary; another, written for the University of Edinburgh, is on the Medical Faculty of the Dutch physician. His studies of Boerhaave, of Louis Pasteur, and of William Osler are excellent. It is indeed a fortunate thing that two departments of the Government should have had at a formative period in its English social history two such servants as Morant and Newman. The many honours which were bestowed upon Sir George Newman included the honorary degrees of D.C.L. of Durham and LL.D. of Edinburgh, McGill, Toronto, Glasgow, and Leeds, the Honorary Fellowship of the Society of Apothecaries of London, and the Freedom of the New York Academy of Medicine. He was knighted in 1911, the K.C.B. followed in 1918, and the G.B.E. in 1935. A lifelong member of the Society of Friends, he was for forty years the anonymous editor of the *Friends Quarterly Examiner*. He married in 1898 the daughter of Samuel Thorp, of Alderley Edge. There were no children of the marriage, and Lady Newman died in 1946.

C. A. RAISON, M.B., F.R.C.S.

We announce with regret the death of Mr. C. A. Raison, the well-known Birmingham surgeon. He died in the Queen Elizabeth Hospital on May 8, at the age of 57, after a long and painful illness. Cyril Alban Raison received his medical education in the University of Birmingham and qualified M.B., Ch.B. in 1914. After serving as house-surgeon to Prof. Leedham Green, he joined the R.A.M.C. and saw active service in Salonika. He was promoted major and had charge of a surgical division. In 1921 he obtained the F.R.C.S., and in 1928 he became assistant surgeon to the General Hospital, Birmingham. At the time of his death Mr. Raison was honorary surgeon to the United Hospital, and he was also on the staff of the Children's Hospital. He was lecturer in operative surgery in the University and was consulting surgeon to the Nuneaton General and Infectious Diseases Hospital.

In 1939 he volunteered again for the R.A.M.C. He was not accepted, because his health was already impaired. Despite this he continued with his heavy practice and took his full share in the treatment of air-raid casualties in the General Hospital and later on in the nearby underground hospital in the centre of the city.

Raison had a staunch spirit in a slight frame. He was a general surgeon and a strong defender of the genus. Perhaps he would have said that he was trained at a time when a young British surgeon received the finest all-round training surgeons ever have received or ever will. Certainly his large practice and the fact that he was in great demand locally bore testimony to the excellence of his work. He loved his association with the University and with teaching, and gave much time and thought to these matters. Raison was one of them, probably be part of a medical school. He wrote little, but was because he rejoiced to be a part of it. He wrote little, but was sound and thoughtful. He was one of the men who carried on the great traditional teaching of the craft of surgery as it has been carried on since the beginning. It is for this that he will be remembered, and he would have wished for no better memorial.—H.D.

Dr. DAVID STONE, who died at his home in Northampton on April 10, was born in 1865 at Ardochrig Farm, East Kilbride, Lanarkshire. He was educated at St. John's Grammar School, Hamilton, and Glasgow University, where he graduated M.B., C.M. in 1887, proceeding M.D. in 1903. After acting as an assistant in Coatbridge he undertook voyages as ship surgeon to Canada and the U.S.A. and on his return acted as lecturer in a number of practices before finally settling in Northampton in 1889. There he carried on his own practice until his retirement in 1936. In this year he was made chairman of the Northampton Insurance Committee. Dr. Stone was a keen ambulance worker and lecturer, and was made an honorary serving brother of the Order of St. John of Jerusalem. He was an ardent linguist in both ancient and modern languages, an omnivorous reader, and had a profound knowledge of the Bible. His ministry was most valued among the Open Brethren, with whom he had a lifelong association. His steadfast Christian principles, his unshakable integrity, and the kindness of his disposition earned for him the respect and love of his fellow townsfolk and patients. His death severs yet another link with a past generation. He is survived by his wife, his son, Dr. Noel Stone, and two daughters.—N.E.S.

Dr. PETER FRANKEL, who died at Colindale Hospital on April 16 at the early age of 33, came to this country from Breslau, Silesia, in 1933. He was the nephew of Dr. Felix Pinkus, the celebrated dermatologist, and was a descendant of the great Ehrlich. He graduated M.B., B.S. as a student at St. Bartholomew's Hospital in 1939. He worked for a time at the British Postgraduate School of Medicine and thereafter took posts in several general hospitals. He proceeded M.D. in 1943, joined the R.A.M.C., and served in Belgium and Germany with the rank of captain. On his return to this country Dr. Frankel obtained the M.R.C.P. At this time he became engaged to Dr. Diana Owen, who was also resident there. He was appointed registrar to St. John's Hospital for Skin Diseases shortly before his death, which terminated a promising career. A man of wide culture and varied interests, he was always conscientiously concerned with the welfare of his patients. His sincerity and charm of manner, his depth of feeling, coupled with a fine sense of humour, made him always welcome to a wide circle of friends, who deeply mourn his loss. Bernard Shaw once said there are friends who are not taken from us when they die but only when we die. Peter Frankel was such a friend. We offer our deepest sympathy to his mother and sister and his fiancée.—B.W.R.

Dr. GEORGE THOMSON died at the age of 75, on April 16, at the Derbyshire Royal Infirmary. He graduated M.B., C.M., at Aberdeen University in 1894. The village of Codnor, Derbyshire, and the surrounding district mourn his passing. He was medical practitioner there for forty-four years until his retirement in 1945, and he knew them all, even to the second and third generations. He was, moreover, a first-rank medical practitioner, a hard worker, conscientious almost to a fault, and there seemed no limit to his tireless energy. He played a good game of golf and tennis and enjoyed an occasional dance. Yet he found leisure for medical reading and study, and was at all times conversant with the current medical advances in his own field of activity. The writer assisted him for a time on

¹ *British Medical Journal*, 1947, 1, 548.

included Mr. Miller's firm, the agency found employment for nurses at the salary which the nurses required. Mr. Miller introduced the nurses to the patient, rendered the accounts to the patient, collected the sum due, and paid it to the nurse after deducting 10% commission. The Council conceded that there was nothing wrong in an agency supplying nurses on the basis that they made their own bargains, nor in a nurse supplied at the Council's maximum rate making some additional bargain with the patient and recovering some extra money. As the court pointed out, if the nurse would not work for the maximum fixed by the Council, the curious position would be reached that the patient would have to pay one sum to the agency and another to the nurse. In the view of the court this was not a condition for securing the proper conduct of the agency. The provision in the Act was aimed at undue fee-snatching : it had often been found that unscrupulous agents charged excessive fees and prevented people from getting proper employment unless they paid such fees or imposed on their employees improper or undesirable terms. If, however, a nurse demanded, say, seven guineas a week and the agent told the patient that that was the charge, that was perfectly proper conduct by the agency. Mr. Justice Singleton agreed that the condition objected to was not in any sense necessary for securing the proper conduct of the agency but went outside anything of the kind. The court therefore upheld the justices' decision that the maximum fee in this licence was invalid.

The issues in this case affect about 20,000 nurses, half of them in London.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

The following degrees were conferred on May 15.

HUNTERIAN TRUSTEES

A meeting of the Hunterian Trustees was held at the Royal College of Surgeons of England on May 12 with the Earl of Athlone in the chair. Others present were Sir Alfred Webb-Johnson, B.A., President of the Royal College of Surgeons of England, Sir Arthur Keith, F.R.S., Sir Holburt Waring, Mr. R. H. Burns, F.R.S., Prof. Matthew J. Stewart, Viscount Leverhulme, Prof. F. Wood Jones, F.R.S., Sir Frank Colyer, Prof. H. A. Harris, Sir Adolphe Abraham, and Dr. E. Bellingham Smith.

The Trustees inspected the surviving parts of the Hunterian Collection, once more on exhibition in the museum. They also approved the plans for rehousing the Collection in the new museums which are to be built to replace those destroyed by enemy action.

Medical Notes in Parliament

The Mental Treatment Rules, 1948, and the National Health Service (Emergency Mental Treatment) Regulations, 1948, were presented to Parliament on May 25. On the same date the Report to the Lord Chancellor on the number of visits made and patients seen by the Visitors of Lunatics between Oct. 1, 1947, and March 31, 1948, was laid on the Table.

The Mental Treatment (Adaptation of Forms) Rules, 1948, were presented to Parliament on May 26.

NATIONAL HEALTH SERVICE

On May 27 Mr. PETER FREEMAN asked whether the Minister of Health would provide for a reduction or abolition of premiums to the National Health Service where no claim had been made after a period of years in order to discourage frivolous applications and encourage personal responsibility for good health.

Mr. BEVAN, in reply, said the National Health Service was free to all and there were no premiums of any kind. The benefits available did not include cash benefits, which were provided under the National Insurance Act.

provided under the National Insurance Act, 1911. Answering Colonel STODDART-SCOTT, Mr. BEVAN said a relatively small part of the cost of the National Health Service was met by a grant from the National Insurance Fund. This grant would not be allocated to any particular part of the Service. As there would be persons eligible for the full benefits of the Health Service, although they made no contributions, the Service obviously was non-contributory. Colonel Stoddart-Scott suggested that as on July 5 Mr. Bevan was not going to provide the service laid down in the Act, he should advise his colleagues to reduce the weekly contributions of 8d. or 10d. which every member was asked to pay toward the Health Service.

Mr. BEVAN told Mr. COLLINS on May 27 that he accepted in principle the recommendations of the Committee on the Remuneration of General Dental Practitioners. Discussions were about to take place with representatives of the dental profession and he hoped to reach a speedy conclusion on the detailed application of these recommendations.

RADIOACTIVE SUBSTANCES BILL

On May 28 Mr. ASKIRIN BEVAN moved the Second Reading of the Radioactive Substances Bill, the purpose of which, he said, was to secure protection for the health of workpeople and of the public against the harmful effects of exposure to and of the public against the harmful effects of exposure to dangerous radiation. He said the safety code of the X-ray and Radium Protection Committee, which was appointed about twenty-five years ago by the Medical Research Council, was not always observed. The need for the Bill was greater because the country was on the verge of a vastly extended use of radioactivity. The power of the apparatus used and the quantity of radioactivity available had increased enormously. There was under construction in this country a cyclotron which would give 300,000,000 volts. In medicine x-ray apparatus had reached 250,000 volts and betatrons might shortly be used giving 30,000,000 volts. Artificial radioactive substances were becoming freely available for therapeutic use. All had different rates of emission and were difficult to define. This difficulty had led to the unusual structure of the Bill. The relatively cheap rates at which many of these products might be available would mean that, unless they were restricted in their use, untrained people might do themselves great damage. The effects of exposure to radioactive substances of high emission rates were often insidious and the consequences known only after a number of years. Therefore experts advised that it was necessary to provide for the protection of the public. Safeguards had been introduced into this Bill which had not been present in the Bill which was introduced a year ago. The present Bill had been discussed in the House of Lords and he believed it could

be treated as an agreed measure. After outlining its provisions Mr. Bevan said the Bill gave the Minister unusual powers, many of which were novel. It was an enabling measure to enable the Minister concerned to lay down Regulations with a particularity which could not be attempted in a Bill. That these powers should not be subject to abuse, a powerful advisory committee was to be appointed. Bodies who would be asked about the appointment of representatives included the Medical Research Council, the three Royal Medical Colleges, and the Royal Medical Corporations of Scotland. He laid emphasis on the protection of the population from the commercial exploitation of radioactive substances put into soap, face-cream, lipsticks, and that sort of thing.

Special Powers

Mr. RICHARD LAW said Mr. Bevan had established the case for the Bill. If these substances were to be controlled and individuals protected from them, the special powers asked by Mr. Bevan were necessary. Nevertheless dangers arose from these great powers. Clause 5 might produce stagnation in scientific research and development. The powers might be used to give an advantage to one section of the medical profession over another. The radiologist or the radiotherapist might be given a corner in this field. Dermatologists had long used methods of radiotherapy and were afraid some monopoly might be set up to their disadvantage. All these dangers would be averted if the Advisory Committee did its work properly. He asked whether the Committee could initiate advice as well as give it when asked.

Mr. BEVAN said he would see the Bill was, if necessary, amended so that advice could be given over the whole field.

Mr. LAW said it was desirable that the Advisory Committee should give the Ministry of Supply advice on the allocation of the costly and scarce tracer materials which were produced at Amersham.

Major VILSON said many radioactive materials had a short half-life. Preparations of them must be kept under control hour by hour until used. The phrasing of the Bill did not fit that process. The customary training of medical practitioners and dispensers did not fit them for this work. It seemed dangerous for the Bill to propose that when a person applied for a licence, that licence should be granted automatically for three months before a scrutiny was made. Disposal of waste was a difficulty. Laboratories had become radioactive to such an extent that they had to be abandoned. The precautions taken at Harwell were excellent, but some other establishments had not been so thorough in the past.

Mr. SOMERVILLE HASTINGS said that forty years ago he had been casualty officer in a teaching hospital when x rays were a new toy and their dangers were not appreciated. The doctor and technician who then worked with him died of x-ray cancer. The effects of exposure might become apparent many years afterwards. Therefore he welcomed the Bill. He asked whether the persons who used x rays daily in boot shops were sufficiently protected. He was afraid that the doctors on the Advisory Committee might be too large an extent be specialists. He asked Mr. Bevan to include in that Committee ordinary physicians and surgeons and perhaps a few dermatologists as well.

Mr. HAROLD DAVIES asked if there was a guarantee that no radioactive effluents could get into the rivers and into the drinking water.

Mr. BEVAN said no case had occurred of anyone being injured at Harwell by radioactive substances. The Bill should have been introduced long ago. In New York six corporations distributed radioactive substances for medicine and industry. He hoped the Government would let the Dominions receive supplies of radioactive isotopes.

Mr. BEVAN said that nothing in the Bill prevented dermatologists being placed on the Committee. When the Bill said that radioactive substances, as defined by Regulations, could only be prescribed by duly qualified doctors and dentists, "duly qualified" meant those persons designated by the Advisory Committee. The normal curriculum of the ordinary doctor was not sufficient to give him the facilities to use these substances. That had been recognized by all the learned bodies concerned. He asked Mr. Davies that there was no danger of contamination of the water.

Mr. BEVAN said a second time without a division.

CIVIL SERVICE ENTRANTS

Lord SIMON OF WYTHENSHAW said Lord Miersy drew attention to the fact that Sir Percival Waterfield, the first to be selected for the Civil Service, was reported to have been a medical student at the time of his selection. He asked whether the Government intended to consider the possibility of selecting medical graduates for the Civil Service.

into the administrative service and 50% of applicants for foreign service scored marks for personality and intelligence which represented complete failure. Among those who failed, 60% had University or College scholarships and 20% had State scholarships. He asked whether the Government suggested any alterations in the present system.

Lord SIMON OF WYTHENSHAW said he had spent forty-eight hours at Stoke d'Abernon and had witnessed the tests of civil service entrants. [These tests are the subject of an article which appears at page 1094 of this issue.] He explained the system of grading candidates and said the science of interviewing was changing rapidly. Large industrial firms were beginning to adopt CISSB methods. Prejudice had been imported into the matter because of the practice of having a professional psychologist as one of the three interviewers. The Civil Service Selection Board was trying to understand the mental characteristics of individuals and estimate how they were likely to develop. That was not a job to be left to amateurs. The only way one could judge was by seeking the help of a psychologist.

Lord LINDSAY OF BIRKER said Sir Percival Waterfield had not spoken about the CISSB. He was talking about the distressingly low standard of qualities shown by candidates who came before the Board. Lord Lindsay said that in his own experience in Oxford at the beginning of the war he saw the whole of the candidates for the University and was struck by the fact that a small number of boys, mostly State scholars, were no good at all. Their health was hopeless, they had no physique, and they made one despair. They were able boys from poor homes and small schools for whom a State scholarship meant everything. Competition for the scholarships had ruined their health and usually ruined their minds.

Lord MORAN, referring to psychological tests in the Services during the war, said it was not so much that psychology was in its infancy as that a few of those practising it were in their dotage. If the failures to which the first Civil Service Commissioner had referred were chiefly in the personality tests, it was necessary to remind the House that these tests of personality had never been validated in peace or war. He thought the majority of candidates seemed convinced that the Stoke d'Abernon week-end was far fairer than the short interview given in the past.

Other Methods of Selection

Lord ELTON believed that the traditional tests for the Civil Service were over narrow in that they confined themselves to selecting persons likely to absorb readily and reproduce lucidly the ideas of other people. In the traditional examinations the successful candidate needed to possess neither common sense nor honesty, neither courage nor adequate physique, nor even an original mind. The selection of Rhodes scholars without any form of written examination was simpler than the CISSB arrangements and had been extremely successful. Statistics in the United States which compared the careers of one hundred Rhodes scholars with a hundred persons possessing the highest intelligence quotient were markedly in favour of the Rhodes scholars. He had been in the United States, Canada, and Rhodesia and had met some hundreds of members of the Selection Committees for Rhodes scholarships. Almost without exception these men greeted the suggestion with horror and apprehension. He himself suspected that psychology was making exaggerated claims.

Lord PIERCY said the tests at Stoke d'Abernon were as complete as possible and in addition every available piece of information about the candidate was carefully scrutinized. The psychologists were fundamental to the whole system. They provided and often devised the techniques. No system at present devised could be 100% perfect, but the selection of officer candidates during the second world war was done with an impressive margin of superiority over all other methods by similar procedures in which selection groups used the psychologist and in the case of the War Office the psychiatrist also. The National Institute of Industrial Psychology, which had specialized for twenty-five years in procedures for vocational selection, had supplied psychologists to the Admiralty and the War Office and to the Manpower Planning Department. The three psychologists at Stoke d'Abernon were all former members of the Institute's staff. A number of big firms, including Unilever, Imperial Chemical Industries, and the Phillips Electrical concern selected their intake of new people by these group procedures.

Lord CHERWELL repudiated the idea that the average mental level of students was lower than before or that the Universities were selecting the wrong people and training them wrongly, or that the old-fashioned methods of entry to the Civil Service by competitive examination should be superseded by the impressions of psychiatrists and professional interviewers.

Lord PAKEMHAM, replying for the Government, said the reconstruction examinations or competitions had been required

V.D. in R.A.F.—Mr. ARTHUR HENDERSON denied, on May 26, that any order had been issued at a conference at H.Q. 85 Wing B.A.F.O., in November last that medical officers who found members of the Forces suffered from V.D. should divulge their names and the nature of their disease to the commanding officer of the unit.

Discussion of Table
by change

In Northern Ireland the notifications of scarlet fever increased by 11 as a result of a general rise in the incidence of this disease.

The figures are given as follows:
 (a) The 120 administrative counties
 (b) London (administrative county)
 (c) The 10 principal towns in Eire.
 (d) The 10 principal towns in Great Britain.
 A dash — denotes no cases; a blank space denotes no return available.

	. 1948	1947 (Corresponding Week)
(a)	(a)	(a), (b), (c), (d), (e)
(b)	(b)	(b)
(c)	(c)	(c)
(d)	(d)	(d)
(e)	(e)	(e)

* Measles and whooping-cough are not notifiable in Scotland, and the
are therefore an approximation only
† Deaths from measles and scarlet fever for England and Wales, London
(administrative county), will no longer be published.
‡ Includes primary form for England and Wales, London (administrative
county), and Northern Ireland.
§ The number of deaths from poliomyelitis and polio-encephalitis for England
and Wales, London (administrative county), are combined.
¶ Includes puerperal fever for England and Wales and Eire.

COMING EVENTS

The Institute of Almoners

An extraordinary general meeting of the Institute of Almoners (Tavistock House (North), Tavistock Square, London, W.C.1), will be held at the Midland Hotel, Manchester, to-day, Saturday, June 5, at 2.30 p.m., when there will be an informal discussion on "July 8 and After" to be opened by Miss M. J. Roxburgh (teaching hospital), Miss J. M. Beaumont (municipal hospital), and a speaker from a public health department. After the business meeting Dr. Mary D. Sheridan will speak on "The Deprived Child."

William Withering Lectures

Prof. John F. Fulton, M.A., M.D., Ph.D., Head of the Department of Physiology, University of Yale, will deliver the William Withering Lectures in the Anatomy Theatre of the Medical School, Birmingham, on Monday, Tuesday, Wednesday, and Thursday, June 7, 8, 9, and 10, at 4 p.m. each day. His subject is "Functional Localization in the Frontal Lobes and Cerebellum, with Particular Reference to the Operation of Frontal Leucotomy." Members of the medical profession and students of medicine are invited to attend the lectures.

Research Defence Society

The annual general meeting of the Research Defence Society will be held at 26, Portland Place, London, W., on Tuesday, June 8 at 3.15 p.m., when the Seventeenth Stephen Paget Memorial Lecture will be delivered by Prof. P. A. Buxton, F.R.S., entitled "Tsetse Flies and the Development of Africa."

Faculty of Radiologists

The annual meeting of the Faculty of Radiologists will be held at Cardiff on Friday and Saturday, June 11 and 12. The programme is as follows: At Cardiff Royal Infirmary, June 11, 9.45 a.m. meeting of Fellows; 10 a.m., annual general meeting and admission of Fellows; 11 a.m., meeting of Diagnosis Section, discussion of "Pneumoconiosis in South Wales," to be opened by Prof. Jethro Gough, Dr. C. M. Fletcher, and Dr. L. G. Blair. A demonstration of apparatus will be given and pathological specimens shown to the Therapy Section; 2.15 p.m., meeting of Therapy Section, discussion on "The Treatment of the Leukaemias," to be opened by Dr. R. Bodley Scott, Dr. H. B. May, and Dr. J. S. Fulton. A demonstration on pneumoconiosis will be given before the Diagnosis Section; 7 for 7.30 p.m., dinner at the Royal Hotel. At the Institute of Engineers, June 12, 10 a.m., joint meeting of Diagnosis and Therapy Sections, discussion on "Cerebral Tumours," to be opened by Dr. M. H. Jupe, Prof. Dorothy Russell, Mr. Brodie Hughes, and Mr. J. Jackson Richmond. Further information may be obtained from the honorary secretary of the Faculty at 45, Lincoln's Inn Fields, London, W.C.2.

West London Medico-Chirurgical Society

Prof. E. N. da C. Andrade, D.Sc., Ph.D., F.R.S., will deliver the Cavendish Lecture before the West London Medico-Chirurgical Society at the Royal Society of Medicine (1, Wimpole Street, London, W.) on Tuesday, June 15, at 8.30 p.m. His subject is: "The Atom and Its Energy."

St. Bartholomew's Hospital

Barts men who practise in Gloucestershire, Herefordshire, and Worcestershire will hold their annual dinner at the Abbey Hotel, Malvern, on Friday, June 18, when Lord Horder will be the guest. Any Barts men in an adjoining county who wish to attend should communicate with Dr. J. S. Cookson, County Health Department, 35, Bridge Street, Hereford.

Royal Medical Benevolent Fund

The 112th annual general meeting of the Royal Medical Benevolent Fund will be held at the Medical Society of London, 11, Chandos Street, Cavendish Square, London, W., on Tuesday, June 29, at 5 p.m., with the President, Sir Alfred Webb-Johnson, Bt., P.R.C.S., in the chair. The statement of accounts for the year ended Dec. 31, 1947, will be presented and officials and committee of management for the ensuing year will be elected.

Congress in Prague

The General Assembly of the International Federation of Sports Medicine will be held in Prague as previously arranged on June 29, 1965, and the Seventh International Medical Congress of Physical Education will be held on July 1-5 in connexion with the Eleventh Sokol Festival. Visits to places of interest will be organized as required. Inquiries should be addressed to: Prof. MUDr. Jirí Král, Praha II, Vladislavova 15, Czechoslovakia.

A new hospital for epileptics has just been opened in the north-western part of the Ashdown Forest. Patients of the hospital are free to leave at 10 o'clock. Inquiries and applications should be sent to the National Association for Mental Health, 10, Bedford Square, London, W.C.1.

Captain H. J. O'M., R.S., M.B. 1890
Rt. Col. commandingarrison to
Mr. Walter Rowley
Howard's Hospital

RECEIVED

SOCIETIES AND LECTURES

Sunday

ONDON JEWISH HOSPITAL MEDICAL SOCIETY.—At Rose Hertz Hall, Woburn House, W.C., June 6, 3 p.m. "Some Clinical Entities Frequently Misdiagnosed," by Mr. Hamilton Bailey.

Monday

DINBURGH UNIVERSITY: PHYSIOLOGY CLASSROOM.—June 7, 5 p.m. "Medicine in Literature," by Dr. Douglas Guthrie.
ESTMINSTER HOSPITAL SCHOOL OF MEDICINE: MEYERSTEIN LECTURE THEATRE, Horseferry Road, London, S.W.—June 7, 5.30 p.m. Clinico-pathological demonstration. Discussion: "Whooping-cough."

Tuesday

BRITISH ASSOCIATION OF PHYSICAL MEDICINE.—At Hospital for Sick Children, Great Ormond Street, London, W.C., June 8, annual meeting, 2.30 p.m. Clinical Demonstration of Physical Medicine in Children, by Dr. F. B. Kiernander. 3.30 p.m. Discussion. At Royal College of Surgeons, Lincoln's Inn Fields, London, W.C., 5.30 p.m. Annual general meeting. 7 for 7.30 p.m. Annual Dinner at the College.
STITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—June 8, 5 p.m. "Occupational Dermatitis," by Dr. F. R. Bettley.

Thursday

STITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—June 10, 5 p.m. "Tuberculous Infections of the Skin," by Dr. L. Forman.
EST LONDON HOSPITAL, Hammersmith, W., June 10, 8.30 p.m. "Haematemesis and Melena: An Investigation of the Place of Surgery in its Treatment": First Alex. Simpson Smith Memorial Lecture by Mr. Norman Tanner.

Friday

ATIONAL HOSPITAL, QUEEN SQUARE, MEDICAL SCHOOL, London, W.C.—June 11, 5 p.m. "The Cerebellum Reconsidered" by Prof. John Fulton (Yale).
JYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS, 58, Queen Anne Street, London, W.—June 11, 2.15 p.m. "Accelerated Painless Labour," by Prof. N. C. Louros (University of Athens).
NIVERSITY COLLEGE LONDON.—At No. 1 Lecture Theatre, University College Hospital Medical School, W.C., June 11, 4.30 p.m. Holme Lecture: "Burns and Fluid Balance" by Prof. Oliver Cope (Harvard Medical School).

Saturday

RREY COUNTY MEDICAL SOCIETY.—At Milford Sanatorium, June 12, 3 p.m. Clinical meeting.

APPOINTMENTS

The Director of Medical Services is included in a list of officials who have been appointed Nominated Official Members of the Legislative Council of the Colony of Kenya.

SPAY, WILLIAM D., M.B., Ch.B. Clinical Tuberculosis Officer, Liverpool.
TWEART, A. B., M.D., D.P.H., Divisional Medical Officer, National Health Service.
SALLACE, W. H. S., M.D., D.P.H., Divisional Medical Officer, National Health Service.
ARWICK, NINA S. S. SEAFORD, M.B., Ch.B., D.O.M.S., Assistant Honorary Pathological Surgeon, Macclesfield General Infirmary.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

um.—On May 24, 1948, at Victoria Hospital, Lichfield, to Joyce (née Iran), wife of Dr. A. R. Elsom, Burntwood Lichfield, a daughter—Ruth Margaret.
h.—On May 19, 1948, to Dr. Margaret Lush, wife of Dr. Brandon Lush, daughter.
Jellough.—On May 23, 1948, to Dr. and Mrs. J. K. H. McCullough, daughter—Elizabeth Jane.

MARRIAGES

ey.—Pearson.—On June 5, 1948, at Christ Church, Summerfield, Birmingham, Charles James Constantine Davey, M.B., Ch.B., M.R.C.S., L.R.C.P., son of Mr. and Mrs. W. E. Davey of Dordridge, Warwickshire, to Gwyneth Jane Pearson, M.B., Ch.B., daughter of Dr. and Mrs. A. S. Pearson, Gifford Road, Birmingham.
rison.—Myles.—On May 8, 1948, Dr. Leslie Gordon Morrison, M.C., to Dr. Aletina Myles.

DEATHS

ey.—On May 25, 1948, at Bampton, Oxford Thomas Ronald Davey, M.B., Ch.B., L.R.C.P., aged 62.
d.—On May 24, 1948, at Worthing Oliver Field, M.D. Ed.
—On May 27, 1948, at 22, Gladstone Place, Aberdeen, Frank Austin Gill, D.Aberd.
d.—On May 24, 1948, at Deal, Thomas Lyon, M.D. Ed., aged 66.
d.—On May 24, 1948, at Guy's Hospital, London, S.E., George Edens Efall, M.B., B.S., late R.A.F.V.R.
nair.—On May 26, 1948, at Avondale, Marple, Cheshire, Frank Gordon Macnair, M.D. Ed., aged 46.
—On May 21, 1948, at a private nursing home in Dublin, Louis Augustus Moran, L.R.C.P. & S.I. & L.M.
n.—On May 26, 1948, Sir George Newman, G.B.E., K.C.B., M.D., R.C.P., of Grims Wood, Harrow Weald, Middlesex, late Chief Medical Officer, Ministry of Health, aged 77.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Morphine in Obstetrics

Q.—What is the action of morphine on unstriated muscle generally, and on the uterine muscle in particular? What influence does morphine exert on the uterine muscle in the treatment of the following conditions: (a) threatened abortion; (b) placenta praevia ("expectant" treatment); (c) prolonged labour due to secondary uterine inertia caused by rigid soft parts? Does morphine even in full therapeutic dosage abolish or in any way modify, the contractility of the pregnant uterus?

A.—Morphine does not have a specific action on all plain muscle throughout the body. The organs whose muscle is said to be influenced are the stomach, small and large bowel, and the uterus. Its action on the alimentary tract is still subject to dispute, its well-known constipating effect being said to be due either to diminished peristalsis and to contraction of sphincters or to a generalized increased tone of the intestine associated with diminished contractions. The views of different authorities are contradictory, and it would seem that the effects may not only vary in different parts of the bowel but with the dosage. Whatever its effect, it is not known whether morphine acts directly on the muscle or whether it interferes with the peripheral reflex. In practice, however, it seems highly probable that morphine often influences bowel function indirectly through its action on the central nervous system. This is particularly true in the case of post-operative ileus, where the beneficial effect of morphine may well be due, in part at least, to the relief of anxiety, nervousness, and pain, which can be important aetiological factors.

There are again conflicting opinions on the effect of morphine on the uterus, but the balance of experimental work carried out on the human subject goes to show that morphine has no significant direct effect on expulsive uterine contractions associated with abortion, labour, or the puerperium. It does, however, reduce uterine spasm in labour and is therefore valuable in all forms of incoordinate uterine action. Here, too, its effect is probably explained by its action on the brain: by relieving pain and nervous tension it frees the uterus from the influence of an overactive autonomic system. More efficient action of the uterus and easier dilatation of the cervix, which are commonly observed when morphine is used in cases of inertia or of normal labour, are due to the removal of the inhibitory effects of the central nervous system rather than to any direct action on the muscle. When the obstetric condition is characterized by haemorrhage, as in placenta praevia or abortion, morphine is again valuable, but only because it induces comfort and quiet, which in turn favour haemostasis. If morphine does not inhibit uterine contractions and may, even indirectly, facilitate dilatation of the cervix, it might be argued that it is contraindicated in threatened abortion. This is not necessarily true, for morphine does not initiate dilatation of the cervix, and by ensuring mental and physical rest it helps to remove possible uterine irritants.

Parkinson's Disease

Q.—(a) Is the operation of division of the pyramidal tracts in the spinal cord of value in the treatment of Parkinson's disease? What are the indications and results?

(b) The fact that Parkinsonian tremor disappears when the patient is asleep leads me to ask whether hypnosis has ever been tried as a means of controlling tremor and, if so, with what degree of success?

A.—(a) This operation has been carried out on small groups of people with Parkinson's disease. It is too early yet to give an indication of its value, but there is no doubt that some patients with severe paralysis agitans have benefited. The purpose of the operation is to destroy the upper motor neurone, either in the cerebral cortex or in the pyramidal tract itself,

for the disturbance in paralysis agitans is caused by the pyramidal tract working in the absence of extrapyramidal control. It follows that a reduction in the disability caused by the Parkinsonism is in direct proportion to the degree of pyramidal hemiplegia. Because of this, the operation should be considered only in severe cases and preferably if only one side is affected.

(b) All abnormal movements arising as a result of disturbances of the basal ganglia disappear during sleep, but they return on waking, whatever may have been the nature of the sleep. The disturbances are in no way due to psychological causes and are not benefited at all by hypnosis.

Treatment of Ringworm

Q.—What is the most successful treatment for *tinea pedis* and *tinea cruris*? Is dithranol ointment safe in a 1% strength? Is it advisable to do anything about sterilizing clothes, shoes, etc., as was at one time recommended in the Middle East, and, if so, what method would you advise?

A.—*Tinea cruris* clears rapidly with dithranol, and a 1% strength is quite safe. Response to treatment of ringworm of the toes is more variable and depends upon the chronicity, the presence or absence of infection of the nails, the degree of secondary eczematization, climate, and other circumstances. Various treatments are appropriate to different stages. It is generally wise to use a variety of local measures at night, turn and turn about, among which dithranol ointment is valuable, as is carbol-fuchsin paint or:

Hydrarg. perchlor	0.5%
Brilliant green	0.5%
Spirit	ad 100
Make a paint.					

Various other newer fungicides may be used in the morning. The feet should be washed, thoroughly dried, and well powdered. It is wise to sterilize stockings and shoes with formalin and to avoid infecting bath mats, etc., by using slippers for bathing.

Treatment of Callosities

Q.—What is the best treatment for a callosity on the sole of the foot, opposite the second metatarsal head? The condition may persist for years, and paring, salicylic acid, and rings have little effect.

A. Callosities of the type described are commonly found in association with pes cavus, or with simple flattening of the transverse arch of the foot. There is impairment of the intrinsic muscles with consequent inability of the toes to exercise their important function of sharing the pressure of weight-bearing and walking with the metatarsal heads. Treatment should be directed primarily to the correction of the underlying foot defect. The function of the intrinsic muscles will often be much improved by a suitable course of physiotherapy. This should include intensive foot and toe exercises, and faradic stimulation of the affected muscles. It is important that the exercises be continued at home for an indefinite period.

These measures should in most cases be supplemented by the provision of a suitable support for the transverse arch of the foot. A "sorbo" metatarsal pad on the removable leather insole is satisfactory. The accurate placing of the pad is important: it should be beneath the necks of the central metatarsals 1/2 inch to 3/4 inch (1.25-1.85 cm.) behind the metatarsal heads. Paring of these callosities is unlikely to give more than temporary relief unless it is used in conjunction with corrective measures of the kind.

Mud Treatment of Rheumatism

Q. Has Putnam mud any special virtues in the treatment of rheumatism? Is there any British product of equal value? I should be grateful for any other information.

A. Putnam mud is the mud deposited at the mouth of the Putnam River, a Czechoslovakian spa, and belongs to the "Czech muds" which include muds of all kinds and peat. The mud is readily obtainable at most of the British spas. It is applied in conjunction with hot douching and is certainly beneficial in the treatment of rheumatism, but they are

not much used away from the spas. The fact that before war Putnam mud was readily obtainable on the market widely advertised made it popular. The action of poultices general as applied in the home is the same as that of any of mud, but special claims are made for alleged radioactivity in some forms of mud. There is as yet no scientific proof that such low-grade radioactivity has anything more than a counter-irritant action. Beneficial effects are more likely to be due to the moist heat and the mild pressure exerted by the pack, which aids the absorption of exudates and stimulates the circulation of the affected part. To obtain the full effect of such treatment a course at an appropriate spa is probably desirable.

Angioneurotic Oedema

Q.—A young man aged 19 suffers annually from hay-fever. He is normal in all other respects. For the past two years, after a course of injections for the hay-fever, he has had frequent attacks of angioneurotic oedema. Repeated examinations have not disclosed the cause, but I think it probable that the hay-fever injections have started the attacks. The only treatment that has had any effect is adrenaline injections, but these have been discontinued as the last one precipitated alarming anaphylactic shock. Belladonna, bromides, etc., have failed. Can you suggest any other treatment?

A.—In the absence of a discoverable cause, the best treatment is likely to be symptomatic therapy with one of the antihistaminic drugs, "antistin" or "benadryl." They should be taken as early in the attack as possible, and can be given prophylactically, especially if side-effects are absent or minimal. The first few doses of benadryl should be taken at home owing to the risk of their making the patient drowsy. Paragraph on "antistin" and "anthisan" with some comment in a leading article appeared in the *Journal* of May 8.

Pitressin in Hypertension

Q.—Is pitressin tartrate useful for lowering a high blood pressure, and is the reduction so obtained permanent? What are the rules governing its use? Are there dangers associated with its administration?

A.—The writer has never heard of pitressin tartrate and find no reference to such a substance. Pitressin tannate, a water-soluble compound, has been used, suspended in peanut oil, to control diabetes insipidus (Greene and January, *J. Am. med. Ass.*, 1940, 115, 1183). The effect of pitressin on the blood pressure in man varies considerably. Melville and Stehle (*Pharmacol.*, 1931, 42, 455) showed that the fall in blood pressure produced by pitressin is not due to vascular dilatation but to the constrictor effect on the coronary vessels leading to the inability of the heart to maintain the blood pressure. For this reason it should never be used in an attempt to lower the blood pressure.

NOTES AND COMMENTS

Antrum or Anatomy.—Mr. DESMOND W. CONWAY, Golden Square, W.1, writes: May I draw attention to a possible misprint in the *Journal* of May 29, which concerns the report of Dr. Julius Lempert's lecture (p. 1045)? He is quoted as saying that his second reason for his use of magnifying glasses, while performing a mastoidectomy, is "you will see for the first time how beautiful the antrum is." I think it should read as "... how beautiful the anatomy is" (of mid-ear). Any otologist performing a radical mastoidectomy will delight in the anatomy of the antrum, but not for reason of its beauty.

Correction.—In our obituary notice of the late Captain E. C. Watson, D.S.O., R.N. (May 29, p. 1054) the phrase "at the close of the war" in the fourth paragraph should have read "at the close of the day."

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY JUNE 5 1948

British Medical Association

SPECIAL REPRESENTATIVE MEETING THE PROFESSION ADVISED TO CO-OPERATE

ANIMATED DEBATES

The Special Representative Meeting, summoned on the requisition of the Council to consider the results of the April plebiscite and the consequent recommendations of the Council as to co-operation in the new Service, was held in the Great Hall of B.M.A. House, London, on Friday, May 28. Dr. J. B. Miller, of Bishopbriggs, presided, supported by Sir Hugh Lett, Bt., President of the Association, Dr. H. Guy Dain, Chairman of Council, Dr. J. W. Bone, Treasurer, Dr. E. A. Gregg, Deputy Chairman, and the chief officials of the Association.

The first hour of the meeting was occupied with discussion on the order of the agenda. Dr. Cove-Smith (Marylebone) proposed that a number of motions critical of the Council, at least one of which called for the Council's resignation, should precede the discussion on the main recommendation of the Council—namely, that on certain understandings there should be co-operation in the new Service. This was opposed by Dr. R. W. Cockshut (Council) on the ground that if this course was agreed to, and the resignation motion were carried, it would immediately take effect, and there would be no Council to present the recommendations to the meeting. To do as Marylebone wanted would be to enter judgment before the evidence was heard. Another member of the Council, Dr. F. Gray, considered that when votes of censure were proposed they should be taken immediately. "I am one of those to be shot at, and I invite you to start shooting straight away." Dr. Dain said it was the crudest suggestion he had ever heard that "you should sack the cook before you have tasted the soup, or at any rate the fish." As Chairman of Council he was prepared to put the case for the Council to the meeting, but if the Council was going to be censured in the first instance it would be impossible to proceed. Dr. Cove-Smith said he did not want to turn the Council out: he wanted to get the information which the profession desired concerning the actions of the Council.

The motion to vary the agenda in the sense desired by Marylebone was lost, 110 voting in favour and 175 against.

Dr. P. C. McKinley (East Yorkshire) moved to request for full information as to how individual members of Council voted on the decision to take the April plebiscite and to advise the profession to co-operate in the Service. It would be wrong, he said, to judge the Council for its precipitate action without first finding out how its members voted. It was only fair to the Representative Body that it should know what led the Council to take this course, and fair also to those members of the Council who would otherwise be wrongly included in the censure.

Dr. Dain said that no record was kept of the voting of individual members, and it would be impossible to give the information desired. What the Representative Meeting wanted to know was what led the Council to make the recommendation which was before the present meeting, that the profession

should be advised on certain undertakings to co-operate in the new Service, and if only representatives would get rid of these preliminary "frills" and get down to business it could be explained to them.

The East Yorkshire motion was lost overwhelmingly.

The April Plebiscite

Dr. H. Guy Dain (Chairman of Council) moved to receive the statement of the results of the April plebiscite.

In doing so he said that it had been the policy of the Representative Body that in matters of the Health Service the responsibility for decision should be placed on the whole of the individual members of the profession. That principle had been maintained throughout the whole course of this very tiresome, prolonged, and awkward negotiation which had been taking place over several years. In order that the responsibility might be placed upon the individual members of the profession for the decision at the moment they must be asked from time to time for a plebiscite. During the last four or five years there had been a constantly changing position, and the Council would be a stupid and unreasonable set of people if they had not been prepared to ascertain the opinion of the profession in the light of the changes which were taking place. In February last the Minister had refused to budge in any way from the Act which had been passed. Most of their time was taken up last year in what proved to be fruitless discussion with the Ministry. Then the February plebiscite was taken and the result was a 10 to 1 majority disapproving of the Service and a 6 to 1 majority against taking part in it. The Minister then began to consider a way out of the deadlock. He made a statement in the House of Commons in which he endeavoured to deal with one of the profession's chief anxieties and promised an Amending Bill which would diminish his own unlimited powers in several directions, the most important being that a whole-time salaried service could not be introduced by Regulation but would require further legislation. The Minister also offered to set up a legal committee to deal with the partnership question, which he had previously refused to consider. He modified his position with regard to the compulsory basic salary, and said that this should now be a matter of option. He also agreed that there should be free publication, not only as to professional matters but as to criticism of the Service. These were very important modifications, and therefore the Council said, "The Minister is moving. Let us see what we can do about it." The Council devised a series of questions which were put to the Minister and his answers were obtained. From these they got further information on the position of specialists, their ability to continue in their appointments, their non-liability to compulsory transfer from one hospital to another, the continuance of private beds, and the fact that there was to be no monopoly in hospitals, the Minister having already excluded 200 of them and not proposing to take over private nursing-homes.

There were important statements to get from the Minister. Another assurance of his was that the medical members of management committees of hospitals would be full members with power to vote. He also agreed that all Regulations to be made under the Service should be submitted to the representatives of the profession in draft before they were put on the table of the House of Commons. The Minister said that the Medical Practice Committee's duties would be limited to discovering which were over-doctored areas, and that in the rest of the country any doctor would be free to start if he wished. This had modified the position with regard to direction very materially. He had agreed that they should be free to choose their partners and assistants and arrange the duties of their practices. He (Dr. Dain) agreed then, as he did now, that the position did not sufficiently safeguard the freedom of the profession, but it was a new situation. The discussion which took place in the Council was not unanimous, and there was a feeling in some quarters that the Minister had made such modifications as would enable acceptance of service to be considered. On the other hand, there were those who thought that the concessions were not sufficient. What were they to do? The Council drew up a Report which stated fairly what the Minister had offered and what he had not offered, and, after putting this before the members of the profession, thought the proper thing to do was to ask for their opinion by another plebiscite. This was coupled with the statement that in the view of the Council these modifications, while they registered progress, did not sufficiently safeguard the profession's freedom.

It had to be discovered what the members of the profession thought of the new situation and of the value which was to be attached to the Minister's offer. The Council did not take the responsibility for the final decision as to entering the Service, and the plebiscite accordingly was taken.

All that he asked the meeting now to do was to receive the results of the April plebiscite. Criticism had been made of the speed with which that plebiscite was taken, but the Council was of opinion that there had been talk over this matter for so long and in such detail that every member of the profession was in a position to answer the simple question without requiring several weeks to think about it. Therefore an immediate answer was requested.

The results of the plebiscite were before the meeting. A long time ago it was decided that the profession would not be asked to refrain from taking part in the Service unless at least 13,000 general practitioners agreed to stay out. The results showed that the division of opinion in the Council was reflected in the plebiscite figures. The previous majority had diminished so that only 9,500 general practitioners voted against joining the Service. This number was significant of the fact that the offers of the Minister at that time did not satisfy a large proportion of the profession but they as a Representative Body had been placed in a very difficult position because, although the majority which they themselves had laid down was not obtained, the guarantee that had been given to the people must be implemented, namely, that they would not be held to their vote if there was not a sufficient number against service. The resolution of the Council had suggested co-operation on conditions, and they thought when they saw the second plebiscite figures that it was desirable to see how far they could get. After the Minister's first statement in April they obtained further modifications, and they went to the Ministry for further talks, the result of which was embodied in the letter from Sir William Douglas which had been circulated.

"Premature Action"

Dr. Mona Mientaghton (Newcastle-upon-Tyne) moved:

That the Council's action in calling for a third plebiscite so quickly after the second one was premature and indicated approval of the previous action which had been offered, and prejudiced the voting. It was therefore proposed that such a step should only have been taken after a Special Representative Meeting.

On the occasion of the February plebiscite the profession were given a fortnight to consider the offer which was presented to them. On the occasion of the April plebiscite, after a very long discussion, resolved to accept the offer. The previous plebiscite had been held by the Representative Body, and the Council in

making such a decision on its own incurred a great responsibility. Within five days the plebiscite papers were in the hands and had to be returned within ten days, which meant very little time was given to arrange meetings or to discuss with other members how much the Minister had conceded, whether what had been given was no more than a "pig in a poke." This hasty decision to take the plebiscite was interpreted as meaning that in the Council's view the Minister had given the profession what it required. The plebiscite forms were sent out and the only lead given was in a single sentence to the effect that in the Council's view the freedom of the profession was still not sufficiently safeguarded. The taking of the plebiscite should have been left to the decision of the Special Representative Meeting.

Dr. H. H. Goodman (Newcastle-upon-Tyne) said that Dr. Dain seemed to imply that the precipitate action of the Council was due to a changed situation which suddenly confronted it. At the previous Representative Meeting his Division tried to bind the hands of the Council more or less; it asked that there should be no retreat on the principle of retaining the right to buy and sell practice, and Dr. Dain had replied that priority should not be given to any single one of the principles and that they stood or fell by all of them. But the Council had broken this undertaking. The April plebiscite was a tactical error of the greatest magnitude and not justified by the meagre concessions which the Minister had made. The plebiscite had thrown the rank-and-file into complete confusion, and the lack of unity in the Council itself was reflected in the vote of the profession. The plebiscite had split the profession far more effectively than Mr. Bevan could have dreamed of doing. The Council threw away every vestige of leadership when it decided to take the plebiscite. It did not even take up a neutral attitude; it embarked upon an active policy of appeasement, as shown in the leading articles in the *British Medical Journal*. What else could the Council expect but the complete liquidation of the majority obtained in February? The action of the Council was precipitate and unnecessary, and he believed it was *ultra vires*.

Dr. J. C. Arthur (Gateshead) said that as a member of the Council he had spoken against the urgency with which the plebiscite was taken. This could only be excused on two grounds: (1) that the profession was fully informed of the position, and (2) that the Council was aware of a great change in professional opinion following the Minister's statement. The profession was not fully informed. Up to January of last year the Minister gave away nothing. Then, when he was threatened with the big stick of a medical boycott, he agreed to discussions on Regulations. Within a week of the starting of these negotiations it was obvious that he had no intention of amending the Act. The February plebiscite gave the big stick again into the hands of the profession, and the Minister promised to amend the Act. The Council's action in calling for the April plebiscite at once gave the impression that some dramatic change had taken place. He agreed that it was necessary to hold the plebiscite, but it was held prematurely. There should have been more time to explain the issues to the profession. They should have held on longer, perhaps not with an expectation that all their demands would be met, but at least to make sure that the Minister did not repeat his performance of last year and go back on his promise.

Dr. I. G. Innes (Hull) said that they seemed to have run away and lost all their gains. In his view the result of the April plebiscite was not a true one at all.

Mr. N. Ross Smith (Bournemouth) said that in his Division the decision to hold the plebiscite was regarded as one of a number of actions which had compromised the profession and had prejudiced the final decision. It was made public even before the Council's representatives met the Minister that another plebiscite would probably be held. The action of the Council in calling for a plebiscite might have been constitutional, but it was a gross blunder and failure of duty. The Council had forgotten its obligation as an executive body of the Association to maintain the Association's principles and policy, and had been willing to allow the profession to be compromised into acceptance of this Act.

Dr. P. J. Gibbons (Council) said that when he was elected to the Council last July he felt it was a position of trust both to the Representative Body and particularly to the doctors of

SPECIAL REPRESENTATIVE MEETING

erpool and Lancashire who had elected him. He had done
 utmost to fulfil his trust. They had all regarded the result
 the first plebiscite as a great victory, and in response to it
 id to public opinion the Minister, an astute politician and a
 an of first-class endowments, made a statement in the House
 Commons which seemed to indicate that a compromise might
 possible. A group of members who had met the Minister
 Health made their report, and, while he himself was not
 satisfied that they had got all they were fighting for, he felt
 that they had caused the Minister to move a considerable dis-
 nce on the road, and he for one had no hesitation in making
 p his mind that the April plebiscite was immediately neces-
 ary. He had been impressed by the relatively small response
 to the Independence Fund. If doctors all over the country
 meant what they said the least they could do was to back up
 their protestations with hard cash. The Council was entitled
 to ascertain what change, if any, had occurred in the feeling
 of the profession following the Minister's statement
 Dr. R. T. G. Craig (Newcastle-upon-Tyne) said that they had
 nce again been out-manœuvred and mismanaged. The majority
 f doctors in his area had signed the bond, but immediately
 he results of the April plebiscite were announced a change of
 feeling took place. In the neighbourhood in which he prac-
 tised there were 11 doctors who had been unanimously against
 acceptance, and now there remained only himself. The
 partners, and three others who were sticking to their bond. The
 making of the plebiscite had prejudiced the vote and the action
 of the doctors.
 Dr. E. A. Gregg (Deputy Chairman) said that only one issue
 was involved in the motion—namely, whether the action of the
 in the plebiscite was wise. He held that it was. A great deal
 had been done. The fact that the

Dr. E. A. Gregg (Deputy Chairman) said that only one issue was involved in the motion—namely whether the action of the Council in taking the plebiscite was wise. He held that it was the only thing that could have been done. A great deal had been said in this connexion had its origin in the fact that the result of the plebiscite was one that some of them did not like. He himself did not like it, but he was glad to know the facts. At the time when the Council made its decision, at every post office in the country there was a mass of literature placed there by the Ministry ready for release. Amongst it was a document to which they took the strongest exception, telling members of the public to go to their doctor and ask him whether he was going into the Service, and, if he was, to request him to put them on his list. It was of the utmost importance for the Association to get in contact with the doctors before that literature descended, and to get a decision from them with regard to their attitude. "Don't treat the profession as capable of children—they were the most intelligent people and a handful of judgments and at the next as if they were a handful of children." There it was staring them in the face that if the vote of 13,000 was secured they would fight. He himself wanted to fight, but he wanted to know who was fighting with him; that he was not marching on a forlorn hope. He trusted that meeting would not be so foolish as to start censuring the Council, first asking them to take responsibility, and then, when they had done everything in good faith and with the greatest possible wisdom in the circumstances of the moment, censure them for what they had done.

Mr. Woodhouse (Harrow) said that the taking of the Plebiscite was a mistake, and that in the opinion of the Council it was a discreditable business. He considered opinion in the February of 1917 was not a very honourable position to stand

Dr. Woodhouse (Harrow) said that the taking of the April plebiscite suggested that in the opinion of the Council the doctors, who had given their considered opinion in the February plebiscite, were not sufficiently men of honour to stand by their word.

RECOMMENDATION
Advice on Acceptance of Service
Council proceeded to move the first of the

That, despite the importance of the safeguards to the profession's freedoms and the necessity of a substantial section of the profession, the Representative Body should be made available to interest a comprehensive health service should be made available to the community, is prepared to advise the profession to co-operate in the new Service on the understanding that the Minister will continue negotiations on outstanding matters, including terms and conditions of service for consultants and specialists, general practitioners, public health officers and others.

Dr. Dain's Statement

Dr. Dain's Statement

Dr. Dain said: This is really the important business of to-day. You are invited to consider co-operating on conditions. The plebiscite figures showed that the majority which you had established as necessary was not attained and therefore you are not in the position to-day of being able to say whether or not you will recommend the profession to enter the Service. You have had that decided in advance. You cannot go back on your undertaking to the people who signed both plebiscites that unless 13,000 general practitioners agreed to stay out of the Service you would not hold them to their vote against coming in. The issue of continued opposition to entrance to the Service cannot be taken up by you to-day in view of the plebiscite you have given. You are thus saved from making a very important decision and I hope this meeting is saved a lot of trouble as to the action to be taken.

Following the plebiscite with its insufficient majority to decide what it was to say to you. It had to say that it did not even attain a majority for co-operation in the Service.

Following the plebiscite with its insufficient majority the Council had to decide what it was to say to you. It had to say that the majority set out had not been attained and we recommend that there should be co-operation. But co-operation must depend on further consideration by the Minister and his officers of the points which have not been dealt with up to now. There is still as shown in the April plebiscite a substantial minority against accepting service. The Council therefore should continue to send a body of its members to the Minister to persuade him that there was so grave dissatisfaction with the position that what would be the final position which must be accepted to-day. The result of those conversations has been circulated in a letter from Sir William Douglas which has been a practical people every member of this body and now we as practical people must turn up the situation.

There is no doubt that whether the action of the Council in taking a plebiscite was premature or not a large number of practitioners are sufficiently satisfied with the action to accept service. In the resolution of the Council the Council stated that the safeguards of our freedom were not sufficient. Speakers to the previous resolution in the Council had said that the Council has given way. We are said to understand that members of the profession could real and responsible for the printed word. I disclaim entirely any responsibility for the Council having influenced people to go into the Service in advance of the decision of the meeting. Whether it is our duty to attempt to sum up the situation and to say that it is our part to take a fundamental position, whether it can be satisfied that the conditions are safeguarded. I myself voted on April 19th.

I want to sum up the situation and to say that it is our duty to consider the fundamental position, whether we take part in the Service under existing conditions or we can be satisfied that our proper professional freedom will be safeguarded. I myself was quite dissatisfied with the position as expressed on April 1 and following the Council meeting I expressed my opinion quite forcibly in a speech at Shrewsbury to the effect that we were not safeguarded. I was taken seriously to task about it—ones of whom were members of the Council who said I was not expressing the Council's policy and I made a further statement in which I said that I was in favour of the Council's policy and that policy as expressed in what went out with the placard form was that we were not fully safeguarded.

Points which have been Gained

Points which have been Gained

Since then we have made progress. We have succeeded in limiting the Minister's powers and in securing a number of professional freedoms. Let us look on the debit and credit side. What we were most afraid of was the Minister's overall power. He has now agreed to an Amending Act which will limit his powers in creating a whole-time salaried service. This can only be done by fresh legislation, not by Regulation. He has agreed that we shall always be consulted about Regulations and be able to put in our protests before such Regulations are made. I may remind you that, with one exception, which was duly apologized for, for 30 years the Ministry of Health has always dealt with us fairly in the matter of National Health Insurance. Suggestions have been made that we should try to get a particular body to "vet" the Regulations. We have considered that, but we think it is safer that they should all be referred to us in the first instance instead of our having to give evidence to an outside body. In that one particular respect we have obtained a great deal to safeguard our freedom of speech and writing. We have got the right to freedom of speech and writing properly safeguarded. This will be in the terms of service so far

We have got the right to freedom of speech and writing properly safeguarded. This will be in the terms of service so far

consultants or specialists are concerned, and as for general practitioners there will be nobody to interfere with their freedom in that respect. We have talked with the officers of the Ministry and the Minister himself since the Council meeting and we have now reached a position in which the basic salary as a principle has disappeared. The Minister has moved from the position of compulsory basic salary to a voluntary one and we have now agreed that the voluntary basic salary shall be subject to such limitations that it does not offend our principle that we should not be paid by salary.

On the subject of direction we cannot persuade the Minister to put off the action of the Medical Practice Committee, but we have an agreement that that Committee will be able to nominate a few areas which are over-doctored—and who wants to practice in an over-doctored area I do not know—and for the rest the practitioner can set up wherever he likes. We have got now to the position that the Medical Practice Committee will have no power to interfere with anybody starting in practice wherever he likes unless it happens to be in one of those few nominated areas. In fact, therefore, we have obtained the right of the practitioner to take part in the Service wherever he wishes.

Then we have succeeded in discovering something about the conditions which help the consultants' position, and I understand that there is now prepared or in preparation a temporary contract which will deal with the conditions of service but will allow for modification as to remuneration when the Spens Report has been considered. The remuneration will then be indicated to July 5.

We have not been able to alter the Minister's intentions in any way on the question of abolition of goodwill in practices. He is perfectly adamant about it, and we have had no support on that point in Parliament or from any political party. Moreover, many of our own people do not seem to see the importance of it. What we have tried therefore to do is to see how far we can get round this point as well. We have said to ourselves, "What is it that we own when we own goodwill?" We own the right to choose our partners and assistants, to arrange our work with one another, to say who shall succeed us, and to arrange the performance of our duties. The Minister has agreed that we may do all this so long as money does not pass which is in the nature of payment for goodwill. I agree that that will not completely protect us when the Ministry are in charge of the Service, but it has gone a long way to provide for the freedom which I think it is essential we should have before we can join the Service.

We have also been able to attain by argument an important modification in the position with regard to the midwifery service. We have now got it established that any practitioner, whether or not a doctor, but or not may attend his State patient who is on the list if he and she both agree that he should do so. The conditions will not be the same for the man who does not go on the list as for the man who does, but we have practically got rid of that provision in the Act which gives the Minister power to nominate the qualifications of the practitioner taking part in the Service.

The Minister has agreed to put it into the Act that the Executive Council shall elect its own chairman. He has also agreed that a compulsory levy shall be available for the expenses of local medical committees. He has set up a legal body which is to clarify the partnership position, and we cannot get the Amending Act into draft form until we have the report of that body. We have also explored the compensation position. The Minister has agreed that if substantially more than 17,900 practitioners join the Service the amount of compensation annually, £66,000,000, will be increased.

We have failed to the remuneration of general practitioners. We have not agreed to the betterment factor. The Minister has said that when the Service starts on July 5 we can immediately go to the Whitley Council which will be set up to consider general practitioners' remuneration this matter of the betterment factor and the implementation of the Spens Report. We have agreed to go to the present conditions as set out in the Spens Report unless we can prove to the Whitley Council that we have a better one.

We have also agreed to the right of appeal to the courts, but on the subject of the betterment factor we have not succeeded either in

getting rid by agreement of the difficulties which confront us or of modifying them in such a way that they will be practically non-existent. What we have to consider to-day is what we have in mind the progress we have made, our freedoms sufficiently protected. My view is and always has been that should not go into the Service if our freedoms are not sufficiently protected, and I was opposed strongly to going into the Service. But in view of the modifications which we have obtained during the last few weeks I believe we are sufficiently protected to be able to say to the profession that we only can we co-operate in the further negotiations but that the safeguards we require have been effectively secured. (Applause.)

That position did not hold on April 7 when we held a Council meeting, but it does hold on May 28. I know that there is a lot of doubt and fear lest the promises made by the Minister or his officers may not be implemented. But however much we may have been upset and disturbed by the attitude or remarks of the Minister in the past, we have to remember that what we have now is a Government guarantee that an Amending Act will be produced. It is not just a statement of the Minister, but an agreement with the Government, and whether we approve the policy of the Government or not, it is a British Government and we can rely upon its good faith. I do not want to see a new Amending Act produced too quickly. I do not want it to be brought forward until we are quite certain that it provides for all the things for which it is intended.

The Position To-day

I wonder what, if we took another plebiscite at this moment the figures would show. I think there might be a further increase of opinion in favour of service. We do know of large numbers of doctors who are signing on in the Service, large numbers are waiting for the result of to-day's meeting before they themselves take action. They are loyally abiding by their obligation. The obligation placed upon members who vote "No" in the plebiscites to stay out of the Service is, of course, abrogated by the figures of the April plebiscite.

We have obtained a great deal by the open battle method and a good deal more by the "guerilla" action since. For myself I was extremely disappointed over the change of attitude which took place after the Minister's statement in Parliament because I thought that statement left the position very incomplete and that our freedoms were not safeguarded. I was never so disappointed in my life as I was when the figures of the April plebiscite came in. I do not know how the change arose or why it arose except that there were among us a large number of people who were prepared to fight until something had been gained and, having once, so to speak, beaten the Minister on a particular point, were not prepared to wait to see whether the whole of their principles could be satisfied. Somebody has remarked this morning that at the last Representative Meeting I said that we were not going to bargain or to put our principles in any order of merit. I would remind you that we have not given up anything; it is the Minister who has given up all the time.

Are the things that have not been given of outstanding importance? Are they such as would prevent us from taking a proper place in the Service? I am old enough to recall the circumstances of 1911-12, and I foresaw when this controversy began that we should be in exactly the same position as the profession were then. In the end we got all our principles established vis-à-vis Mr. Lloyd George and then we divided ourselves on the subject of money. At that time and after that there was a great split in the profession—a split which had not been foreseen. I put it to you to-day that it is for you to foresee it. We have amongst our members all types of practice and all shades of view. There are those who from the beginning have strongly opposed this Act although in favour of a comprehensive Health Service. There are others who have strongly opposed the Act and would not take part in the Service under any conditions. When the position of those who wish a comprehensive service is satisfied or sufficiently satisfied then they are left with a cleavage of opinion, which began to appear at the Council meeting, between those who did not want the Service at all and those who were satisfied that the Service was now such that we can enter it. We have to face that position and we have to bear in mind the interests of those who are not

I hope that this discussion will be free from emotion, that we discuss without passion the merits of the situation. We are a responsible body of business people looking at a particular problem, and when members speak and speak vigorously on either side I want them to have at the back of their minds the weight of the representation behind them. It would not be reasonable for a representative from any Division to come and speak fiercely either for or against the Council's resolution if he has behind him only the opinion of a meeting of 50 people. In his Division numbers 500 members. He must know that if he determined views he is prepared to express have the support of the majority of the people in his Division. Many representatives will have got their instructions from small meetings (and now that meetings have been very much smaller lately) and the chairman of my own Division took the trouble to ask each member of his Division on a reply postcard whether he would approve or not of the Council's resolution which I am now bringing, and I may say that the result was strongly in favour of the resolution. We are not in a position to continue collecting opposition in view of the non-attainment of the required majority in the recent plebiscite and therefore we have to consider what is the statesmanlike attitude to take in view of this. I have tried to set before you a loud applause.

Co-operation only on Conditions
T. W. Morgan (Kingston-on-Thames) moved as an amendment to the Council's recommendation that the Representative Body, anxious as it was to a health service made available to the community, is prepared to advise the Commission to co-operate in the new Service only on the condition that the rights of continued discussion on outstanding matters involving the terms and conditions of service for consultants, specialists, dentists and other professions, public health officers and others are conferred, and acceptable to all sections of the profession and in accordance with suggestions by Council as issued in the British Medical Journal of May 1, 1948.

...and acceptable to all concerned. The suggestion was made by the Council of May 1, 1948.

The position was that they were now about to enter a service in which they knew very little. The night so far had been of matters of principle, they had now heard from the Chairman of Council that so far as principles were concerned they could enter the Service with a comparatively easy conscience. But there were a number of other things the profession desired, and now before it committed itself. Very little was known about the terms and conditions of service for the consultant and specialist. In the February pamphlet they were anxious to know whether the consultant and specialist group would support the general practitioner, which they did. Now the consultant and specialist group were asking for general practitioner support, and it seemed only decent to give them the support they needed at this stage. He begged them to enter the Service until they knew the whole story, as the Service embodied in the Amending Act. Were the support of his day that the Minister was going to have the support of his back benchers for his amending legislation?

Dr J. Kennedy (Hampstead) said: "I do not think that the appointment day" should be postponed until the amending legislation had been agreed and until the terms and conditions of service of consultants and specialists and of other matters which were still the subject of negotiation had been settled to the satisfaction of the Association. No one could be expected to sign a contract until, even in detail, the consultants and specialists, would certainly hesitate before accepting service with the conditions and terms of service in a nebulous state. Mr. Bevan was using the big stick of refusing compensation if members of the profession did not sign by July 5, yet he said they were free to join or remain out of the Service as they wished. "The danger we form a trade union the better we are to get fair

Lord Horder's Criticisms

Lord Horder (Marylebone) said that Marylebone had put forward an amendment similar to the one moved by Kingston-on-Thames, and was quite unanimous about it, and if he might judge from the letters and telegrams he had received during the last few weeks it voiced the views of a large number of members of the profession. This was not surprising because after all, in the last plebiscite 64 voted against acceptance of service. The Council's resolution hardly did justice to this large body of "not-content" by the use of the quaint phrase "a substantial section of the profession." One did not usually employ the phrase "a substantial section" for a number which was greater than half.

This amendment merely repeats the view taken by the profession in the February plenary. We think the time has still not yet arrived. The reasons for the change in the figures of the two plebiscites have been fully discussed, but they remain somewhat of a mystery. On April 18 the Chairman of Council said at Shrewsbury. You have the opportunity of standing fast in the position you took up at the last plenary. But a few days later the *Journal* printed a longer speech. Dr Dain in which he said that his Shrewsbury speech seemed to have caused some misunderstanding in the profession. Actually, of course, the very fact of taking this precipitate plenary suggested to the profession as a whole that in the minds of the Council the so-called concessions of the Minister were of great importance.

What did happen during those few fearful days? When I made the Chairman of Council sit his words: "For the first time this morning I have heard an explanation when Dr. Dain with his customary honesty and frankness told us that he had been greatly influenced by letters sent to the Journal which have never been published. One letter which went to the Journal over my name and 26 others was treated as put stuff."

Journal over my name and so changed his name into Dr Dain; that letter was not purchased. I learned that some letters changed his name. Whatever the reason, the change was made to lead to doubt and confusion and the result of the purchase, of course, showed that the named unit of the profession no longer existed. I am not cheered when Dr Dain says that up to now we are all together. It would not help me or all of us together if we were not. I would rather be alone and swim. A few people are swimming are more useful than a crowd of people who are not. Was it not a waste of time and money to have so much attention paid to the past in the past? Was it not a waste of the general public's time and money to have so much attention paid to the past in the past?

[illegible]

The turning question which surely, as in the minds of them all, as whether the situation could be retrieved. In Maryland, many thought that the men and women who were signing on daily as the Chairman of Council had said, were signing for economic reasons and from motives of fear, especially the fear that they might lose their compensation. They had not been told what will-o'-the-wisp it was they followed when they signed on. The economic benefits to the general practitioner became more and more illusory the nearer they got to the "appointed day," and consultants and specialists had not even begun to envisage their terms of service. If the Council had become defeatist it could not do any work of this kind. The position was really pathetic. Even that old stalwart, Alfred Cox, to whom the Association owed so much in the past, and who had written him encouraging letters, "was suddenly induced to turn round and run with the rest."

"We do feel" (Lord Horder continued) "that the Council has acted, and in this set of resolutions is proposing to act, past its mandate. It had a mandate not to accept service if more than 13,000 said 'No,' but it had no mandate to tell the doctors to accept service if that figure was not reached in the last plebiscite. The resolutions of Council taken together are surely quite illogical. They say that a substantial section of the profession—more than half—is against accepting service: they say it is a rotten service anyway, but 'let's go in.'

"Where do we go from here? This amendment protests against the present situation. It asks that the *status quo ante* should be restored. It calls on the Representative Meeting to arouse itself and resume the fight. Resistance will grow, and, like all resistance movements against defeatism, it will eventually succeed. The Representative Body is the Association. It should be the Representative Body here and now which initiates its own resistance movement. Resignation from the Association is not going to help us. The setting up of new bodies will not help us. At the last Representative Meeting I moved a vote of confidence in the Association—I did not say in the Council—but the Representative Body can let the Association down; it can let the profession down; it can let the public down, and very badly. I plead for the acceptance of this amendment so that none of these things can happen and we may once more present the solid front that we had last February." (Applause.)

The Plebiscite Justified

Mr. R. L. Newell (Council) said that the February plebiscite showed in no uncertain manner the strength and solidarity of the profession. The whole of their forces were mobilized, and the result was unprecedented. The Minister of Health had to seek a vote of confidence on an Act of Parliament while the plebiscite was being taken. During that disgraceful debate the Minister said many hard things against the Association, but after the result was known he made an impeccable and conciliatory statement in the House and offered not inconsiderable concessions. This found favour on all sides of the House and in the responsible Press. After that statement he, Mr. Newell, proposed in Council that an immediate plebiscite be taken. He knew what effect that statement would have. He admired the clinical acumen of Lord Horder, but he feared that his diagnosis had been warped by the acute symptoms developed in the Marylebone Division. How well justified had been that plebiscite! They had had other facts to go upon. Following the Minister's statement the contributions to the Independence Fund dropped, and some Scotsmen even asked for the return of their contributions. Doctors began signing on for the new Service. Instead of the 17,000 general practitioners who voted "No" in February only 9,500 did so in April. If as a Council they had advised continuing the fight without having that information would they not have been fighting a losing battle?

What was the present position? They could not advise continued opposition, and indeed they had promised not to do so if the majority of 13,000 was not reached. Even if they did so advise it would only mean a repetition of 1911-12. It would place those general practitioners who accepted the Association's advice in danger of loss of capital value.

The Council have decided to recommend co-operation in this Service. There are certain alternatives. We can do nothing

which would be disastrous. We can ask you to co-operate under certain conditions, this would really amount to the issue of a direction for which we have no mandate. It is with some reluctance that I have reached the conclusion that continued opposition would not be successful, and we must be satisfied for the present with the concessions we have obtained

and they are not inconsiderable. We must prepare ourselves for the struggles which lie ahead. Let us face these facts with courage. If we are to co-operate in this Service let us do it with good grace, remembering also that the strength of that negative vote can be used most effectively in the many and important negotiations which lie ahead. The maintenance of a strong Association and a united profession, to my mind, transcends all other issues. I should be distressed to see the disruption of this Association. We have learned what we can achieve by these means, even if to some of you those achievements are not enough. We must stand together and strengthen the only representative body of the profession—the British Medical Association. I ask you to be brave and co-operate in this new Service, and let our motto from this day onwards be eternal vigilance." (Applause.)

Mr. A. V. Powell (South Staffordshire) complained of the presentation of the list given by the Council—one short sentence on the paper sent out with the plebiscite forms—and of the fact that the general secretaries. There had been an attempt to mislead them. They had been told of the things they had won, but not of the things they had not won—

retention of goodwill, right of appeal? They must know what they stood before they signed on the dotted line. Let them make sure what the position was going to be before they agreed to come in.

Dr. J. A. Pridham (Council) said he was out of the room when the plebiscite made its decision, but had he been present he would have supported it. How many men had already signed on for the new Service? In his own Division—one the staunchest in the country—25% or more had already signed, and a great number of others were only waiting loyal to hear the result of that day's meeting. If this Representative Body said, "Accept service," the profession would be in a very much stronger position than if they did the other thing. They could control the situation. Could they imagine a Government more powerful than the present? Was it realistic that the B.M.A. was the only organization outside the T.U. which had stood up to the most powerful Government in modern times and had persuaded the Minister to its point of view? They must take the course of action recommended by the Council. Any other way was suicide.

Dr. O. C. Carter (Bournemouth) said he had opposed the recommendation as hard as he could on the Council and that the Council he would oppose it at the Representative Meeting. He looked on the present debate as the El Alamein of British medicine, for what they did to-day would decide the course of medical practice for a hundred or more years to come. He could not believe that they could achieve more concessions from the Minister once they were all in the bag than they could gain as free men to-day. It was of no use pretending that what they did not get now they would get later on. To offer the last chance of fighting back. He supported the amendment in opposition to the recommendation of the Council.

Dr. Janet Aitken (Council) said that the profession by vote made it impossible for the Council to recommend co-operation. The profession had not the power to prevent the Service from starting on July 5; it had the power to prevent it from being an efficient service, and in her opinion that would be a shameful thing to do. ("Hear, hear.") She thought that they should go into the Service with good will. This was not the end of their fight for freedom. She was quite convinced that individually they would have much more power in fight on relatively small matters once they were in the Service and once the bureaucrats knew that they were willing to make the Service a success if they could.

Dr. J. W. Hope-Simpson (Mid-Herts) supported the Kingston-Thames amendment. They did not want to accept service with many of their essential freedoms still unguarded. A postponement until the position was clarified would be in the interests of the public and of themselves.

Right to Change View

Dr. R. W. Cockshut (Council), who was announced as representing Hendon, said that he was speaking as a member of the Council, and not as representing Hendon, because at a meeting in Hendon, a Division which had 400 members, a resolution approving the Council's recommendation was carried by 17 to 16. He did not take a pessimistic view of the situation. He believed that they had won a very great victory in which they rejoiced. It was open to that meeting to decide to co-operate or to resolve on an all-out fight, but by accepting this amendment they would be doing the worst thing possible, decide to co-operate on some further conditions, putting off the decision, and asking the profession to wait a little longer. He did not think it right that a decision on the framework before them should be delayed, and he hoped the Kingston-Thames amendment would be turned down. He did not understand Lord Horder's reference to stragglers and deserters. Having now, in his opinion, reached a position in which he could enter the Service, if he supported approval he did not see why he should be called by those names. He had voted "No" in the February plebiscite, "Yes" in the April. Since when had it been wrong for a member of Council to give his honest opinion? He might be wrong, but he did not see that it had anything to do with desertion or straggling. He deferred signing on until after that meeting, but if he did it was not for economic reasons, it was because he felt he could go safely into the Service. He was as much attached to the principle of retention of goodwill as any man, but

would hesitate to advise the profession to go headlong into a long and difficult fight on that question, throwing away in doing so all that they had gained. For it must not be imagined that they could continue the fight with Mr. Bevan and keep their gains in their pocket. "If you enter into a fight with the Government and lose, you lose everything. Anybody who advised you to continue to fight would be lacking in a sense of responsibility." If three years ago, when the Representative Body met on the very day that the present Government took office, it had been predicted that the profession would achieve what it had now achieved, no one would have credited the prophecy. It must not be forgotten that the profession agreed to a comprehensive service for 100% of the population, and ever since then it had been the duty of the Council to fight for freedom within that field. They could not possibly arrange an Act of Parliament or a set-up of any kind in 1948 to guarantee their freedom in 1950. Freedom meant constant vigilance and defence, and the only way to secure it was by standing together on the victory they had won and the immense prestige they had gained with the public.

Prof. R. S. Aitken (Aberdeen) urged that to the Council's recommendation there should be added the words after "negotiations" "to a satisfactory conclusion." The hard-headed Aberdonians were in favour of judicious co-operation. They knew that there was not sufficient unanimity to make an all-out fight possible. They knew that 30 or 40% of their number had already signed on, and that any attempt to continue such a fight would end in rather sad results reminiscent of Don Quixote—a mixture of ridicule and pathos.

Dr. H. Simpson (Burnley) did not think the plebiscite results would have been anything like they were if proper leadership had been given. The leadership reminded him of the Duke of Plaza-Toro. It was asking a great deal of people to co-operate without knowing the conditions under which they were to come in.

An Appeal to Realism

Dr. S. Wand (Council) said that any conditions applied to acceptance at this stage meant a long and bitter fight. Two things had to be remembered about the men at the periphery: the first was the right of the man in practice to know exactly where he stood, and the second was the promise to everyone who voted in the February plebiscite that there would be no victimization. From some of the speeches which had been made it might be thought that they had encountered an appalling defeat. Yet the Army was so satisfied with the achievements of the generalship that it had started to go home. That was the present position whether they liked it or not. Only on one point had they failed to achieve gains of the first magnitude. Finally, when they went to the Ministry a day or two previously they were presented with the fact that up to that time 4,000 doctors had signed on, and they well knew that very many men were only waiting until after the present meeting. He begged them to consolidate their gains, and to see to it that in future discussions they retained the strength they had at the present moment. Throughout the country the Press and important bodies of professional men had congratulated the B.M.A. on the magnificent fight it had put up for freedom and the victory it had won.

Dr. S. F. L. Dahne (Reading) said that since the recent plebiscite his Division had been split in half. There was a slight majority in favour of an amendment advising co-operation when the negotiations which were in progress with the Minister had been completed satisfactorily. Sir William Douglas's letter did not satisfy most of them—it was, literally, a "scrap of paper." No trade unionist would enter into a contract on such vague assurances.

Dr. J. A. Brown (Council) said that those who criticized the Council for its action in putting forward this recommendation were apt to speak as if they were the only persons to be considered, and to forget the promise made in the previous plebiscite that only if 13,000 general practitioners refused to enter the Service would the B.M.A. continue to advise doctors to that effect. What did they want the Association to do? Having failed to get the 13,000, did they want another plebiscite? Did they want to advise doctors not to join the Service when they had already joined? When this meeting was over, whether the Council's recommendation was accepted or not, large

numbers of men would go in. The British Medical Association had rightly earned the respect of the Press and the public, also a very healthy respect from the Government. "Do not let us lose that respect or throw away what we have gained. Do you want to do away with the B.M.A. as a negotiating body? If the points we have announced as gained now had been gained in December there would have been no need for the last plebiscite. The earlier plebiscite would have shown that there were sufficient numbers to enter the Service. We have gained practically everything except the retention of goodwill in practice, and that was turned down by the Opposition spokesman, representative of the party that supports private enterprise."

Mr. T. Fletcher (Cumberland) thought that there ought to be added to the Council's recommendation some such words as "provided that such terms and conditions are acceptable to the profession." Dr. W. E. Dorman (Sheffield) came from a loyal Division: in the city of Sheffield only three or four of those in well-established practices had signed on. But in Yorkshire they were realists, and at a very large meeting of his Division the representatives were instructed to support the Council's recommendation as the only sensible course to take. Dr. S. Laurie Smith (Blackpool) considered that acceptance of service should be postponed until terms of service had been clearly defined and approved by the profession as a whole. Dr. Catherine Evans (East Kent) declared that her Division had no confidence in the Minister's word. "If we come in we shall do so disillusioned, frustrated, and with sinking of heart."

Dr. A. C. E. Breach (Bromley) spoke of this "tragic meeting." The smell of appeasement was concentrated here. He was appalled to hear member after member of Council get up and tell them that nothing could be done, and in some cases claim that they had had a victory. Dr. Ward had said that their army was "going home." The truth was that the army thought its leaders had gone home. They had been told about the attitude of the Press and the public. By all means public opinion must be carried with them, but the profession were the protagonists in this fight; they were the only people who understood the issues. Dr. Breach likened what had occurred to a football match. "We have seen our leader falter and stumble in front of an open goal. Was he pulled back from behind by one of his own people?" Mr. G. M. Heutsden (Herefordshire) urged that the Service be postponed until Jan. 1 of next year. His Division was concerned about the fate of consultants and specialists who might be asked to come into the Service knowing nothing about terms and conditions.

Numbers Joining the Service

Dr. Dain, in reply, said that with regard to consultants and specialists the arrangements were that they should continue in their hospital appointments, and receive payment on account. The final payment would be decided when the Spens report had been examined. The Spens report was due to be published on June 9. A number of entirely unsubstantiated statements had been made in the course of the debate. Some members were apparently incapable of appreciating change. The statement that they accepted defeat was nonsense. They had gained the greatest victory against the Government, which had been compelled to accept an Amending Act before the main Act came into force. The decision which the Representative Body was asked to make was based not on the word of a Minister but on the undertaking of the Government. He thought that several of the speeches, including Lord Horder's, had been prepared before the speakers came to that meeting. Lord Horder had spoken of a total change of front. If he had listened to his speech that morning he could not have made that statement. It was of no use talking about going in and fighting back. The figures up to last night of practitioners joining the Service were: in England, out of 16,958, 4,456, or 26%; in Wales, out of 1,003, 337, or 37%; in Scotland, out of 2,768, 1,000, or 36%. To these had to be added the people who were properly waiting for the decisions of that meeting.

"As an old and experienced medical politician I have seen the work done by the Insurance Acts Committee (I was chairman of it for many years), and I know that we have been able to modify conditions of service. If we act properly and

unitedly we can go into this new Service and shape it in accordance with our ideals of what such a service ought to be." He begged that the Council be given authority and not tied to the practically impossible conditions which many amendments on the paper demanded.

Dr. Morgan, the proposer of the Kingston-on-Thames amendment, said that the medical profession was practically the last body of individual enterprise left in this country. "If we don't get what we want now, when are we going to get it?"

The Kingston-on-Thames amendment was lost by a large majority.

Dr. Doris Odum (Bournemouth) moved a further amendment to withhold advice to co-operate until the Amending Act had been passed and approved by a majority vote of the profession. It was vital that the Amending Act should be on the statute book by July 5.

Dr. Dain said that Bournemouth was under a misapprehension. The content of the Amending Bill was in Sir William Douglas's letter which had been circulated; it was merely a question of parliamentary draftsmanship. The provisions with regard to partnerships were omitted because the legal committee had not yet reported. The negotiators had done their utmost to obtain postponement of the appointed day, and might have succeeded had it not been that the National Insurance Act also was due to come into force on that date. The Bournemouth amendment would put the Council in an impossible position and would impugn the good faith of the Government.

The Bournemouth amendment was lost by an overwhelming majority.

A further amendment was moved by Dr. H. H. D. Sutherland (Kensington and Hammersmith) which made advice to co-operate dependent upon the incorporation in the Amending Bill of a provision that practitioners continue to own the goodwill of their practices, be free to practise without direction, be accorded right of appeal to High Court, and be paid by capitation fee only except in certain special cases. The amendment was supported by Dr. Helme (Guildford), who said that this was the one chance of rejecting nationalization of medicine. Dr. Dain said that if this amendment were passed their chances of moulding the Service would be wrecked.

The amendment was lost.

On the main recommendation Dr. J. A. Ireland (Council) expressed the view that the words "on the understanding that the Minister will continue negotiations" were just a pious opinion. The Minister could say "No" at any time and there was nothing they could do about it. Dr. Helme (Guildford): "Have you any faith whatsoever in this Government any more than in Mr. Bevan?"

Dr. Dain said that both these speeches indicated that the speakers had no confidence in the Association whatever. According to Dr. Ireland they had gained nothing, they would do nothing, they were just a set of boobs who were not of any use to anybody. He was tired of this defeatist attitude. (Cheers and counter cheers.)

Recommendation A, advising co-operation on the understanding set out in the motion, was carried by a very large majority.

A Rider

Dr. G. H. Sedgwick (Rotherham) moved a rider:

That the medical profession should accept service under the Act on the understanding that in the event of an Amending Act and terms of service being unsatisfactory to the Representative Body, the profession under the Act should then hand in their resignations and such other steps as are considered necessary by the Representative Body.

This was accepted by Dr. Dain on behalf of the Council and was added to the motion.

Criticism of Council Action

Dr. A. A. Dr. B. Helme (Guildford) moved:

That in view of the position of the situation arising as a result of the Amending Act, and in view of the fact that at the meeting of April 7, this meeting no longer has the support of the Council of the British Medical Association.

Dr. Dain said that the Chairman just made this motion and that it was an opportunity to represent

tives to ask questions. "Before this meeting we were in the bag; now we are in the bag with the string tied."

Dr. D. M. Thomson (Dartford) said that at the last meeting they agreed to support the Council in any action it might take. "We gave them our whole-hearted support and told them to get on with the job—and they have done it jolly well" (Applause.)

Dr. J. Ewart Purves (Bromley) said that if representatives were not to go away with the feeling that in some way the central office had let them down they should be informed of certain facts.

Dr. F. M. Rose (Preston) said that to have such a resolution as this on the agenda, on a day when the Association had gained a great victory, was not a thing of which to be very proud. If they had not achieved 100% victory, it was in the nick of time. Truly, as was said in 1912, the B.M.A. did not know when it had won.

Dr. A. C. E. Breach (Bromley) said it was not for them to cast stones from a feeling of frustration. What mattered was the long-term view whereby real unity in the Association would be achieved. Those of them who loved the Association wanted to see it strong and respected. That was why it was better to face up now to the criticisms made in the background.

Dr. E. A. Gregg asked whether those who introduced resolutions of this character had put forward candidates in the recent Council election and what support those candidates had received.

Dr. Dain said that the members of Council were elected by the Divisions, and could be changed. If the resolutions were carried the members of Council would, of course, resign; they would accept the verdict of the Representative Body although not, save for a small section of them, elected by that Body. He submitted that they had won the greatest victory that the profession had won against a Government. A great many of their aims had been attained, and nothing in the Council's action justified this motion by Guildford.

The motion of "No confidence" was then put to the meeting, and only one or two hands were raised in its favour, and there was a forest of hands on the other side. The result was greeted with loud cheers.

Dr. H. Simpson (Burnley) had a motion complaining of the disastrous effect on the plebiscite of the B.M.J. leaders of April 17 and 24 and calling for "the discharge of the Editor." His reference to a "mismanaged plebiscite" was greeted with cries of "Withdraw."

Dr. R. W. Cockshut (Council) said that the leading article in the *Journal* was a noteworthy example of editorial comment at its best. This motion was the result of disappointment at not finding flaming propaganda there.

Dr. Hale-White (Marylebone) said that nothing could have been further removed from the policy of the Representative Body as expressed at its last meeting than the articles now questioned. They expressed a complete reversal of policy without any consultation with this Body.

Dr. D. L. Little (Dudley) said it would be illogical to censure the Editor of the *Journal* for an offence for which the Council had been exculpated. It would be below the dignity of the meeting.

Dr. E. A. Gregg said that some people wanted a scapegoat. They had had a shot at the Council and, not having been successful, looked for a new victim.

Dr. O. C. Carter (chairman of the Journal Committee) suggested that the motion, besides being in bad taste, was out of order. The articles in the *Journal* conformed to Association policy. They had in the Editor a medical journalist of the first order and the highest integrity—an official who for a long period of years had done a great deal to promote the welfare of British medicine and the prestige of the Association.

Fewer than half-a-dozen hands were held up in support of the motion, which was lost by a very large majority.

RECOMMENDATION B

Unity of the Profession

The Chairman of Council moved the second of the Council's recommendations, namely:

That the Representative Body urges the profession to maintain its strength and unity in order to mould the Service in accordance with

public interest and with enlightened professional opinion and consciously to protect the profession's legitimate freedoms and interests.

In doing so he made no speech.

Many amendments on the order paper were withdrawn. One amendment, to omit the word "legitimate" before "freedoms," as to make "freedoms" unqualified, was lost, and the commendation of Council was carried unanimously.

Dr. A. G. Heron (Bristol) moved to instruct the Council to formulate plans and to set up machinery by which immediate effective action might be taken to enable the profession to join in corporate resistance to any Bill or Regulation which reatered the freedom of the profession or failed to carry out the assurances given about the working of the present Acts.

Dr. Dain suggested that this was really a matter for the Annual Representative Meeting.

The mover, however, pressed for earlier action, and his motion was carried by 97 to 69.

RECOMMENDATION C

The Public and the National Health Service

The Chairman of Council moved the third and last of the Council's recommendations.

That the public be informed that, for reasons outside the control of the profession, the inception of the new Service cannot be followed for some time to come by all the improvements promised by the Government in the medical services of the country, because of the shortage of personnel, medical and nursing, and of the difficulty of providing the necessary premises and equipment.

A similar but somewhat extended motion was moved as an amendment by Dr. A. G. Manley (Richmond) as follows:

That the public be adequately informed that, for reasons outside the control of the profession, the inception of the new Service cannot be followed for some time to come by all the improvements promised by the Government in the medical services of the country, because of the shortage of personnel, medical and nursing, and of the difficulty of providing the necessary premises and equipment, and although the medical profession will make every endeavour to work the scheme, it cannot hold itself responsible for the Government's promises.

It was visualized that there would be failures in various respects owing to the speed with which the Service had been rushed by the Minister, and it was possible that the Minister might turn to the public and say, "The medical profession never wanted this and is not trying to make it work."

The substituted wording was agreed to by 65 to 61 and was afterwards carried as a substantive motion.

There still remained about fifty motions on the agenda, including a number relating to maternity medical services, as well as many miscellaneous motions which might appropriately go to the Annual Representative Meeting, but at 6.30 p.m., after the meeting had been in session for nearly eight hours, a representative suggested that a quorum was not present. A quorum is 180, being one-half the total number of representatives, and a count disclosed that only 137 were in attendance. The meeting therefore terminated after according a vote of thanks to its Chairman.

THE "BASIC" PETROL RATION

Practitioners are reminded that as from June 1 all motorists, whether or not they are in receipt of "essential" or "supplementary" petrol coupons, are entitled to the new standard ration, which, based on horsepower, is designed to afford 90 miles of pleasure motoring per month for the 6-monthly period June to November.

It is important to bear in mind, however, that the Minister of Fuel has announced that it is not intended that motorists whose supplementary allocation is larger than the new standard ration shall receive an increased supply, and in such cases an amount equal to the standard ration will automatically be deducted from the supplementary allocation in the next rationing period.

Practitioners should therefore apply to their local post offices for the standard ration in order to maintain their overall petrol allocation at its present level. In addition this will permit them the unrestricted use of their cars to the limit of 90 miles per month (or 540 miles in the 6-monthly period).

LETTER FROM MINISTRY

The following letter was sent on May 26 by Sir William Douglas, of the Ministry of Health, to the Secretary of the British Medical Association and distributed to Representatives before the S.R.M. on May 28.

Dear Dr. Hill,

The Minister has asked me to write to you about the discussions which representatives of your Association are having with him and with his officers. These discussions will, no doubt, be continuing and finding new grounds to cover. But as your Representative Meeting is to be held this Friday, it occurs to the Minister that you might like some review from him of the position as it is to date.

The main subject has been the content of the Amending Bill which the Minister agreed to propose to Parliament and on which he recently invited these discussions. On that, the Minister agrees that it should include the following provisions:

(1) Whatever clarification of the position of partnerships may be found necessary in the light of the report of the legal committee which is now examining that question, so far as is at all practicable, this clarification will be made to operate retrospectively to July 5.

(2) Provision to make clear that a whole-time salaried general medical service cannot be introduced by Regulations—i.e., would need a further Act of Parliament. This would include provision precluding the imposition by Regulation of any universal full-time consultant service.

(3) Provision for Executive Councils to have the right to select their own chairmen, after the term of office of the present chairmen expires in March next.

(4) Provision to enable the professional member of the Tribunal to be one of a panel of available members and not a fixed individual—so that the member may in each case be suitable in experience and otherwise to the particular issue before the Tribunal.

(5) Power to the Executive Councils, where the local practitioners agree, to cover the costs of the Local Medical Committee (by the necessary deduction from the practitioners' remuneration).

There are other matters on which the Minister feels that there is a reasonable case for adaptation of his proposed arrangements, but which do not need statutory amendment. So far these are:

(a) He has proposed a right to all doctors to opt for the £505 basic salary, with smaller capitation fee, if they so desire. He is impressed by the arguments put to him that an unrestricted option of this kind might often mean that one doctor could gain inequitably at the expense of another. He is prepared, therefore, to stipulate that the option should be only on the recommendation of the Executive Council (having ascertained the circumstances and consulted the Local Medical Committee). But he would propose to give Executive Councils general guidance as to the principles on which they should allow or reject an option, and moreover to give the doctor whose option is rejected a right of appeal to the Minister.

(b) With, as he believes, the full concurrence of professional opinion, the Minister has provided for a system of creating local lists of doctors whose experience is regarded by a professional committee as justifying special recognition in midwifery. For all on this list who undertake the care of a maternity case he has, as you know, already provided for a special fee of 27 7s. Anyone who satisfies the committee of his suitability can join that list and it entails no obligation to undertake any case unless the doctor wishes to do so. Thus a doctor, perhaps towards the end of his practice, who has all the suitable experience but who no longer wishes to undertake midwifery save for a few patients whom he may wish to oblige, could go on the list and yet only take those cases which he wanted to undertake. Others will go, no doubt, with a view to regular and frequent midwifery work—and it will, no doubt, be these with whom the local midwifery authorities will wish to make arrangements to be "on call" to midwives under the Midwifery Acts.

All of this means that there will be some doctors whose names are not on the list just mentioned. As the proposals stand, these other doctors are not, of course, in any way debarred from midwifery. It is simply that they are not recognized for special payment for it under the scheme. It has been represented to the Minister that, as they cannot charge fees to their own public patients within the scheme, they may be undertaking midwifery in some cases without either private fee or public remuneration for it. The charging of a private fee to a patient on a doctor's public list for anything within the field of general medical practice would, in the Minister's view, be repugnant to the whole new health scheme. However, on reflection, he feels that the main objective—of encouraging the development within general practice of groups of practitioners

with rather more than normal aptitude for midwifery—could still be relieved if he introduced a public payment of £5 5s. for all doctors and £7 7s. for those on the special list.

As to freedom of publication, Regional Hospital Boards and Management Committees have already been told by the Minister that no prior consent should be required to any publication, as part of the conditions of service of consultants. No express provision could be made for general practitioners, as under the general terms of service it would be impossible for anyone to require consent as there is no power to do so.

These are all matters on which the Minister has already expressed his willingness, in discussion, to adjust details of the scheme to the profession's views. He will welcome continued discussion, both before and after July 5, and it is inevitable that there will be found other matters on which adjustment is needed in a measure of this magnitude—indeed he will be himself finding points for amendment, no doubt, in other parts of the Act as its working reveals them. He would, however, point out that—as a matter of procedure—it will be necessary to limit as far as reasonably possible the Amending Bill already promised, if it is to be passed quickly and so to relieve any anxieties of those in partnership. For further points, of his own and of others, there will be further opportunities. He hopes to have the profession's collaboration throughout these stages.

Yours sincerely,

WM. S. DOUGLAS.

HEARD AT HEADQUARTERS

Private Patients under the N.H.S.

A leaflet giving full particulars of the position of the private patient under the National Health Service has been prepared by the Public Relations Department of the B.M.A. Supplies are being sent to all Divisions of the Association, but any practitioner who would like copies for distribution to patients should communicate with the local officer of the B.M.A. or with the Secretary of the Association.

Costly Cases

One occasionally hears of parsimony on the part of public authorities, but two cases which point well in the other direction are worth putting on record. Last autumn the Middlesex County Council agreed to be responsible for the treatment at a Swiss sanatorium of a case of tuberculosis of the eye. The cost was not to exceed £100. After four months it approved the continuance of treatment for another three months at a cost of £180. The medical superintendent of the Swiss sanatorium now states that although the very obstinate condition is improving the improvement is slow, and a further two months' treatment is suggested, to which the Council has agreed at a further expenditure of £120. Again, a porter employed at one of the Council's general hospitals is suffering from tuberculosis of the kidneys and bladder, and it is considered that he might have a chance of cure if treated with streptomycin. But it is difficult to obtain the drug for any type of treatment, and therefore this patient also is to be sent to a Swiss sanatorium where it is available. A stay of four months is suggested, and the cost of maintenance and treatment amounts to £60 a month, with travelling expenses in addition. The Council is bearing the cost of the Swiss treatment in these two cases without prejudice to its general policy on the treatment of patients in Switzerland.

Milk Certificates

Mr. J. A. S. was said at one time—and hinted in official quarters—that the certification in the matter of extra supplies of milk for children. When it became necessary to limit priority supply of milk to patients who needed a considerable amount of it, the treatment doctors were said to be interpreting the regulations in a very wide manner. It is interesting, therefore, to find in the recently issued report of the Medical Research Council for the years 1939-45 the following tribute to the medical profession in general carried out their duties. In the context of the Food Rationing, Special Regulations, the Council stated its recognition of the fact that the medical profession is which members of the

medical profession must have been exposed, they continued general to exercise scrupulous care in certification. This is shown by the constancy of the milk consumption by invalids during the period of hostilities when food shortage was becoming progressively more severe."

Holiday Exchanges

There have been a number of inquiries from doctors in France, Switzerland, and Denmark for holiday exchanges with doctors in this country. They generally offer hospitality to a doctor and his wife for a holiday period in exchange for hospitality in this country. If any practitioners are interested in such an arrangement the Secretary will, so far as is possible, put them in touch with doctors on the Continent who have made inquiries in this connexion.

Practitioners Called In

The Regulations governing fees for medical practitioners called in by midwives do not cover such a case as was brought to the notice of the Public Health Committee at its last meeting—that of the medical practitioner called in to attend a confinement (not a "booked" case of his) because the midwife was not available. The question in such cases, which cannot be very infrequent, is whether any statutory authority can be found for the local council's paying the fee. The advice given to the member who raised the question—and it was stated that other medical officers of health to be quite correct—was that a practitioner should have a word with the medical officer of health with a view to persuading the local authority to apply to the Ministry for special sanction for payment of the fee. It is believed that the Ministry would favourably consider such an application, provided it was a local-authority service "booking."

Industrial Medical Officers

A committee of the Association about which too little has been heard, but which is doing a large amount of useful work, is the Industrial Medicine Committee. Under the chairmanship of Dr. Vaughan Jones it has considered many topics, including ethical rules for industrial medical officers, terms of service and lists of duties. A list of duties which it has drawn up runs to thirteen headings, the most important being about the examination of applicants for employment, together with advice on placement, the immediate treatment of medical and surgical emergencies, the examination and continued observation of persons returning to work after absence due to illness or accident, and the periodical examination of employees exposed to special hazards. A very wide and indefinite sphere of work has been opened up to the industrial medical officer when it comes to advice to the management. This may relate to the working environment in general, to special risks entailed in industrial processes, to accident prevention, to hygienic requirements, to canteen facilities, and to the health education of employees. The industrial medical officer, whole- or part-time, is an important factor in the nation's recovery, and his interests are attended to at Headquarters.

OPHTHALMIC BENEFIT

From the point of view of ophthalmologists the administration of ophthalmic benefit by approved societies has not worked smoothly or satisfactorily. Only a few societies have accepted without question a doctor's recommendation that a patient should have a medical eye examination. In the majority of cases societies have disregarded the doctor's recommendation and have limited the grant towards a medical eye examination to the amount—a few shillings—which would be payable for a testing of sight by an optician. Too often this limitation has been extended to cases in which even an optician has recommended a medical eye examination and the society concerned has denied its responsibility for the whole of the ophthalmologist's fee. Somewhat belatedly a categorical declaration has been obtained from the Ministry of National Insurance to the effect that under Article 25 (2) of the Additional Benefit Regulations, 1930, an approved society is required to pay the whole cost of an ophthalmic examination made at its request, or at its authority.

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

Metropolitan Borough Councils.—Fulham, Hackney, Poplar.

Non-County Borough Councils.—Dartford, Radcliffe (limited future appointments), Tottenham, Wallsend.

Urban District Councils.—Denton, Droylsden, Houghton-le-Ring, Huyton-with-Roby, Portslade, Redditch (restricted to few appointments), Tyldesley.

Association Notices

ELECTION OF COUNCIL OF B.M.A.

The following are the results of the election of members of Council by those Groups where there were contests:

Group C (Isle of Man, Lancashire and Cheshire).

D. R. Owen (Chester)	684	Elected
R. Kennon (Liverpool)	575	Elected
F. M. Rose (Preston)	373	
No. of voting papers issued	4,073	
No. returned	878	
Spoiled papers	3	

Group D (Derbyshire, Leicestershire and Rutland, Lincolnshire, Nottinghamshire).

J. Cottrell (Grimsby)	381	Elected
E. C. Dawson (Derby)	279	
No. of voting papers issued	1,526	
No. returned	660	
Spoiled papers	4	

Group E (Bedfordshire, Cambridgeshire and Huntingdonshire, Essex, Hertfordshire, Norfolk, Northamptonshire, Suffolk).

J. C. Pearce (Diss)	417	Elected
J. S. Rens (Welwyn Garden City)	277	
G. Barber (Dunmow)	175	
No. of voting papers issued	2,494	
No. returned	869	
Spoiled papers	1	

Group I (Metropolitan Counties).

Lord Horder (W.1)	1,504	
A. M. A. Moore (W.1)	1,359	Elected
F. Gray (Wandsworth)	1,270	
H. H. D. Sutherland (W.10)	1,204	
J. A. Gorsky (S.W.1)	614	
No. of voting papers issued	6,858	
No. returned	1,704	
Spoiled papers	6	

Group K (Dorset and W. Hants, South Western, Wiltshire).

J. A. Pridham (Weymouth)	419	Elected
G. F. Burnell (Truro)	213	
No. of voting papers issued	1,692	
No. returned	632	
Spoiled papers	4	

Group L (Southern, Surrey)

N. E. Waterfield (Little Bookham)	461	Elected
A. C. de B. Helme (Guildford)	256	
No. of voting papers issued	2,555	
No. returned	717	
Spoiled papers	4	

The following have been elected unopposed:

Group A (North of England) J. C. Arthur, Low Fell, Co. Durham.

Group N (Aberdeen, Dundee, Northern Counties of Scotland, Perth). Mary Esslemont, Aberdeen

Group Q (Border Counties, Glasgow and West of Scotland (Five County Divisions), Stirling). W. Jope, High Blantyre.

CHARLES HILL,
Secretary.

ANNUAL GENERAL MEETING

Notice is hereby given that the Annual General Meeting of the British Medical Association will be held in the Large Examination Hall, Bene't Street, Cambridge, on Tuesday, June 29, 1948, at 12.30 p.m. Business: (1) Minutes of the last meeting, held July 23, 1947; (2) Induction of President, 1948-9; (3) Appointment of auditors.

CHARLES HILL,
Secretary.

EXTRAORDINARY GENERAL MEETING

Notice is hereby given that an Extraordinary General Meeting of the British Medical Association will be held in the Large Examination Hall, Bene't Street, Cambridge, at 12.30 o'clock in the afternoon, or as soon thereafter as the Annual General Meeting of the Association shall be terminated, when the following resolution, with or without amendment, will be proposed as a Special Resolution:

Resolution

That the Articles of Association be altered in the manner following:

(i) By inserting in Article 3 after the words "The Medical Acts" the words and figures "or the Medical Practitioners and Pharmacists Act, 1947."

(ii) by deleting from Article 10(c) in line 6 the words "for India or."

By Order of the Council,

CHARLES HILL,
Secretary.

MIDDLEMORE PRIZE

The Middlemore Prize consists of a cheque for £50 and an illuminated certificate, and was founded in 1890 by the late Richard Middlemore, F.R.C.S., of Birmingham, to be awarded for the best essay or work on any subject which the Council of the British Medical Association may from time to time select in any department of ophthalmic medicine or surgery. The Council is prepared to consider the award of the prize in the year 1949 to the author of the best essay on "The Value of Orthoptics in the Treatment of Squint." Essays submitted in competition must reach the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1, on or before Dec 31, 1948. Each essay must be signed with a motto and accompanied by a sealed envelope marked on the outside with the motto and containing the name and address of the author. In the event of no essay being of sufficient merit the prize will not be awarded in 1949.

SIR CHARLES HASTINGS CLINICAL PRIZE

The Sir Charles Hastings Clinical Prize, which consists of a certificate and a money reward of 50 guineas, is again open for competition. The following are the regulations governing the award:

1. The prize is established by the Council of the British Medical Association for the promotion of systematic observation, research, and record in general practice; it includes a money award of the value of 50 guineas.

2. Any member of the Association who is engaged in general practice is eligible to compete for the prize.

3. The work submitted must include personal observations and experiences collected by the candidate in general practice, and a high order of excellence will be required. If no essay entered is of sufficient merit no award will be made. It is to be noted that candidates in their entries should confine their attention to their own observations in practice rather than to comments on previously published work on the subject, though reference to current literature should not be omitted when it bears directly on their results, their interpretations, and their conclusions.

4. Essays, or whatever form the candidate desires his work to take, must be sent to the British Medical Association House Tavistock Square, London, W.C.1, not later than Dec. 31, 1948. The prize will be awarded at the Annual General Meeting of the Association to be held in 1949.

5. No study or essay that has been published in the medical press or elsewhere will be considered eligible for the prize, and a contribution offered in one year cannot be accepted in an

subsequent year unless it includes evidence of further work. A practitioner in any year is not eligible for a second award of the prize.

6. If any question arises in reference to the eligibility of the candidate or the admissibility of his or her essay the decision of the Council on any such point shall be final.

7. Each essay must be typewritten or printed, must be distinguished by a motto, and must be accompanied by a sealed envelope marked with the same motto and enclosing the candidate's name and address.

8. The writer of the essay to whom the prize is awarded may, on the initiative of the Science Committee, be requested to prepare a paper on the subject for publication in the *British Medical Journal* or for presentation to the appropriate Section of the Annual Meeting of the Association.

9. Inquiries relative to the prize should be addressed to the Secretary.

KATHERINE BISHOP HARMAN PRIZE

The Council of the B.M.A. is prepared to consider an award of the Katherine Bishop Harman Prize of the value of £75 in 1949. The purpose of the prize, which was founded in 1926, is to encourage study and research directed to the diminution and avoidance of the risks to health and life that are apt to arise in pregnancy and child-bearing. It will be awarded for the best essay submitted in open competition, competitors being left free to select the work they wish to present, provided this falls within the scope of the prize. Any medical practitioner registered in the British Empire is eligible to compete.

Should the Council of the Association decide that no essay submitted is of sufficient merit, the prize will not be awarded in 1949, but will be offered again in the year next following this decision, and in this event the money value of the prize on the occasion in question will be such proportion of the accumulated income as the Council shall determine.

The decision of the Council will be final.

Each essay must be typewritten or printed in the English language, must be distinguished by a motto, and must be accompanied by a sealed envelope marked with the same motto and enclosing the candidate's name and address. Essays must be forwarded so as to reach the Secretary, to whom all inquiries should be addressed, at B.M.A. House, Tavistock Square, London, W.C.1, not later than June 31, 1948.

Branch and Division Meetings to be Held

LEICESTERSHIP BRANCH.—At Stamford Hotel, Stamford, Thursday, June 10, 2 p.m. Annual meeting.

Meetings of Branches and Divisions

DERBYSHIRE AND GALLOWAY DIVISION

The Annual General Meeting was held on May 16 at 3 p.m. at the Derbyshire Arms Hotel, Derby, and was attended by about 60 members. Mr. R. L. Beveridge was elected Chairman for 1948-9.

At the business of the meeting reference was made to the death of Mr. J. M. Allen, of Kirkcudbright, who was Scotland's oldest medical practitioner.

There was considerable discussion on the increase of the medical practitioners' mileage fees, and the difficulties of the medical profession about the granting of sufficient

GLoucester Division

The Annual General Meeting was held on May 12 at the Royal Gloucester Hotel, Gloucester, and was attended by about 60 members. Mr. H. J. H. Jones was elected Chairman for 1948-9. The meeting was directed at the Gloucester Arms Hotel, Gloucester, and was attended by a large number of members. The meeting was held at the Gloucester Arms Hotel, Gloucester, and was attended by a large number of members.

The meeting was held at the Gloucester Arms Hotel, Gloucester, and was attended by a large number of members. The meeting was held at the Gloucester Arms Hotel, Gloucester, and was attended by a large number of members.

LINCOLN DIVISION

A general meeting of the Division to which all practitioners in the area were invited was held on April 25, with Dr. A. M. Maiden in the chair. Sixty-nine members and non-members were present. The meeting discussed the situation created by the statements made by the Minister of Health in the House of Commons and the Minister's replies to the questions put to him by the B.M.A. representative. In his opening remarks the chairman made the point that if he agreed to serve under the Act as amended medicine became a monopoly, and it would be very easy for the Minister to introduce further amendments leading to full-time State medical service.

At 6 o'clock Dr. Potter arrived and was invited to address the meeting. After reviewing the changed situation he pointed out that the consultants' position had not been altered very much though the Minister had given assurances that part-time practice would be the usual thing. He also pointed out the difficulties which were arising from the proposed £300 salary element for three years. The view of the Council was that the safeguards were not complete without retention of goodwill, and this was the only point on which the Council had given a lead. He concluded by saying that the responsibility for the final decision must lie with those who were concerned with working the Act, and it was essential to find out who was willing to stand out in view of the new propositions, as it was impossible to rely on the previous plebiscite owing to the change of position. Dr. Friskney proposed that "this meeting does not favour acceptance of the N.H.S. Act in its amended form." The proposition was carried by 35-14, with about 10 abstentions.

SHEFFIELD DIVISION

A complimentary dinner was given at the Royal Victoria Hotel, Sheffield, on April 22, by the Sheffield Division of the B.M.A. Dr. Henry Brown, Dr. Brown was Honorary Secretary of the Division for 25 years. Mr. W. J. Lytle was in the chair, and Dr. Mackinnon and Dr. J. Nunan reviewed Dr. Brown's work for the Association in proposing his health. Dr. Brown was presented with a cheque subscribed to by members of the Division, and a harvest was given to Mrs. Brown.

H.M. Forces Appointments

ROYAL NAVY

Acting Surgeon Lieutenant T. A. Daly to be Surgeon Lieutenant.

ROYAL NAVAL VOLUNTEER RESERVE

Surgeon Lieutenant-Commander R. M. Marshall has been placed on the Retired List.

Temporary Surgeon Lieutenant I. F. Barwell-Clarke has been transferred to List 1 of the Permanent R.N.V.R., in the rank of Surgeon Lieutenant.

Temporary Acting Surgeon Lieutenants H. Revill, P. B. McDermott, C. J. H. Paget, I. T. Holloway, A. S. Ireland, J. L. Hadley, and A. R. L. Abel to be Temporary Surgeon Lieutenants.

ARMY

Colonel D. W. Beamish, M.C., late R.A.M.C., having attained the age for retirement is retained on the Active List (superannuation). Lieutenant Colonel C. V. Menemara, from R.A.M.C., to be Colonel.

ROYAL ARMY MEDICAL CORPS

Lieutenant-Colonel F. Holmes, O.B.E., having attained the age for retirement is retained on the Active List (superannuation).

Majors (War Substantive Lieutenant-Colonels) J. C. Reed, O.B.E. and D. T. Swift, O.B.E., to be Lieutenant-Colonels.

Major P. O'Shea to be Lieutenant-Colonel.

Captains (War Substantive Majors) P. B. Longden and N. D. Lance to be Majors.

Captain I. MacPhail to be Major.

Captain L. R. Shore, retired and re-employed, has ceased to be re-employed.

Short Service Commissions.—Captain (Temporary Major) A. P. Laing and Captains C. P. O'Hanlon, I. McC. Carmichael, E. T. O'Dwyer, and M. S. C. Rooney, from Emergency Commissions, to be Captains. Lieutenants P. M. F. McGarry, W. G. L. Allen, G. H. F. Beith, D. Dexter, D. Hamilton, J. S. Inkster, D. M. O. Lowry, R. H. McVean, J. R. Page, N. C. Rees, M. Redfern, A. K. Thomas to be Captains. Lieutenants J. G. P. Power, A. I. Cook, J. K. Anderson, H. T. Jones, I. McAlpine, J. B. O'Donnell, A. D. Roy, H. J. Moss, J. B. Walker, M. H. Pettigrew, and J. I. Kileour, from Emergency Commissions, to be Lieutenants.

SPECIAL LIST (EX-INDIAN ARMY)

BRITISH ARMY

Lieutenant-Colonel W. F. Cooper has retired and has been granted the honorary rank of Colonel.

Major (War Substantive Lieutenant-Colonel) R. I. Reid has retired and has been granted the honorary rank of Colonel.

Major A. H. O'Malley has retired and has been granted the honorary rank of Lieutenant-Colonel.

Captain A. V. Barker, M.B.E., has retired.

Lieutenant S. N. Eate has retired and has been granted the honorary rank of Major. (Substituted for the notification in a Supplement to the *London Gazette* dated Jan. 9.)

BRITISH MEDICAL JOURNAL

LONDON SATURDAY JUNE 12 1948

PULMONARY VALVULOTOMY FOR THE RELIEF OF CONGENITAL PULMONARY STENOSIS

REPORT OF THREE CASES

BY

R. C. BROCK, M.S., F.R.C.S.

Surgeon to Guy's Hospital

The surgery of the heart may be said to have begun in 1896 when Rehn (1897) first successfully sutured a wound of the heart. Until a short time before this a semi-mystical, mediaeval attitude prevailed in relation to the heart, which was generally thought to be untouchable surgically. Thus even as late as 1883 Billroth declared that the surgeon who attempted to suture a wound of the heart would lose the respect of his colleagues. Rehn's epoch-making operation demonstrated conclusively that the heart of man was, in some measure at any rate, tolerant of interference. Surgeons were quick to profit by this lesson, so that within ten years Rehn was able to collect reports from the literature of 124 cases of a wound of the heart treated by suture.

The early promise of the development of direct cardiac surgery engendered by Rehn's success was not fulfilled: development there has been, but most of the progress has been by indirect methods. Operations have been conducted upon the surface of the heart and upon the great vessels near the heart, but very few indeed have been done upon the actual substance or internal structure of the heart except for injury or removal of retained foreign bodies.

The successful ligation of the patent ductus arteriosus by Gross and Hubbard (1939) and resection of aortic coarctation by Crafoord and Nylin (1945) were followed by the brilliant work of Blalock and Taussig (1945) in the treatment of *morbus caeruleus*. By anastomosing a systemic artery to the pulmonary artery Blalock was able to relieve cyanosis in those cases of "blue babies" in which an inadequate supply of blood was going to the lungs—usually those in which a pulmonary stenosis was present. Even this carefully thought out and brilliantly executed operation, which has brought relief to so many hundreds of sufferers otherwise doomed to disability and death, is an indirect operation and not a direct one upon the substance or structure of the heart itself. It is in the nature of a by-passing operation to avoid the stenotic zone.

Earlier Operations for Valvular Stenosis

In 1913 Doyen tried to divide what was thought to be a stenosed valve in a patient aged 20 suffering from pulmonary stenosis. He did this by introducing a small tenotomy knife into the right ventricle: the patient died several hours later, and necropsy showed that a subvalvular rather than a valvular stenosis existed. About the same time Tuffier (1913) dilated a stenosed aortic valve with his finger by invaginating the wall of the aorta, but he did not open the heart or the aorta; the patient was said to be improved. Souttar (1925) used a method of direct digital dilatation of the mitral valve and his patient survived, although it appears from the case report that no true mitral stenosis was present.

The most sustained effort to solve the problem of relief of valvular stenosis by direct attack on the valves was made by Cutler and his associates (Cutler and Beck, 1929); they used a tenotome in their first three cases and a cardio-valvulotome in four others. Their first patient survived four and a half years and was thought to have been improved; six other patients died soon after operation, as also did single cases reported by Allen and Graham (1922) and Pribram (1926).

These early efforts were succeeded by a long period of inaction, and in the minds of many these operations of a quarter of a century ago seem to have proved that direct surgical attack on the diseased valves of the heart is too dangerous to be practicable.

Now, we must remember that these attempts were indeed made nearly a quarter of a century ago. Since that time there have been great advances in surgery and anaesthesia. Enormous developments have been made in the whole field of intrathoracic surgical technique; great strides have been made in pre-operative and in post-operative care, particularly in regard to blood transfusion and oxygen administration, and, more recently still, chemotherapy has heralded a new era. With our present knowledge and experience of intrathoracic operations we can understand the difficulties in the way of these early pioneers. It is no discredit to them that they did not succeed; they deserve only the greatest credit and recognition for their courageous efforts. At the same time it is important to realize that this accumulated experience and development of the last 25 years has entirely altered the prospects of success, and he would be blind who did not realize that the time has now come to try the matter again. When one examines the heart post mortem in patients dying of valvular disease and contemplates the minute size of the orifice through which the whole life-blood of the body has to be forced it is impossible not to feel that this simple mechanical obstruction must be capable of relief by surgery. The relief of such mechanical derangements is one of the oldest functions of surgery, and surgery is wanting in some part until it has been able to relieve cardiac valvular stenosis. It should require no special imagination to grasp this—even a student in training could postulate it.

Objections continue to be raised that even if the stenosed valve is successfully dealt with the secondary alterations in cardiovascular mechanics may prove disabling or fatal. This is no fundamental objection to the operation; it is merely a potential difficulty that has to be assessed or overcome. By timorous meditation we arouse fear and postpone success. Meditation and planning are essential, but in such circumstances as this, faced with a problem beset with so many and obvious hazards, the first step must be to

assess the essentials. The essential fundamental is the stenosed valve which holds up the passage of blood: the relief of this stenosis must be the ideal to be aimed at. Relief by indirect methods has its place and may prove ultimately to be the wisest and best course to adopt, but until proved otherwise, relief by direct attack must be our goal.

The day must surely come when direct operations upon the substance and structure of the heart will be as firmly established and as successfully conducted as operations upon the lungs, brain, and other major systems and viscera that for so long defeated our efforts. There can be little doubt that there will be fundamental changes in technique, such as possibly those associated with temporary discontinuance of the circulation through the heart while it is being operated upon. In the meantime we must attack the problem and begin the development of a technique for intracardiac operations, for unless begun the task can never proceed.

It is with this justification, therefore, that I record three cases in which a direct operation was performed upon the pulmonary valves in an attempt to relieve a pulmonary stenosis: these three patients are alive and their cardiac condition has been improved. It is not suggested that these three cases provide the solution to the problem, but they would appear to be of sufficient importance to deserve description at this time. So far as I know, apart from the earlier attempts mentioned above, they are the only recorded examples of successful direct operations upon the heart to relieve disease within the heart, apart from the repair of injuries and the removal of foreign bodies.

I am indebted to my cardiologist colleague, Dr. Maurice Campbell, for his unstinted enthusiasm, co-operation, and medical and moral support in this most difficult venture; the selection of suitable cases would not have been possible without his knowledge, skill, and partnership.

The Problem of Congenital Pulmonary Stenosis

The postulate of the Blalock-Taussig or "blue-baby" operation is that an inadequate supply of blood is going to the lungs and that by joining a systemic artery to the right or left pulmonary artery an additional amount of blood can be delivered to the lungs for oxygenation. The stenosed area is thus by-passed. The immediate results of this operation can be dramatically successful and can usually be described as excellent. It is so far not possible to assess the late results, since Blalock's first operation was done only recently as November, 1944. Two possible drawbacks to the procedure immediately suggest themselves. First, that the fistulous communication may not grow *in vivo* with the child and thus will prove ineffective in later years. Observations upon growing animals and upon patients during after several years should provide the answer to this. Secondly, an arteriovenous leak or artificial ductus arteriosus is created—a condition for the relief of which, if it occurs as a congenital maldevelopment, an operation has been considered necessary. To this objection Blalock rightly replies that the fear of complications in the future is no justification for allowing a patient to die of asphyxia in the present; he also believes that the existence of the patent interventricular septum, which is present in most of these patients as a part of the tetralogy of Fallot, necessitates the usual drawbacks that a patent ductus arteriosus entails.

The relief of the obstruction itself by direct operation certainly overcomes the second and greatest objection: the direct supply of blood would be provided to the lungs and the disadvantages of an arteriovenous leak and of the artificial ductus arteriosus that this condition

It is usually stated that the stenosis in these cases almost invariably subvalvular or infundibular and is therefore not amenable to relief. In fact this is not so: a proportion of cases of Fallot's tetralogy have a valvular stenosis either with or without a subvalvular stenosis; in addition a further proportion of cases of *mitralis caeruleus* occur in which a pure pulmonary valvular stenosis is present. It is not as yet possible to give with certainty the exact proportion of cases in which valvular or diaphragmatic type of stenosis exists; there can be no doubt, from my observations so far, that the incidence is far higher than has been supposed. Investigators are proceeding to decide this more exactly.

When a valvular stenosis exists it is of a diaphragmatic nature: the fused valves form, as it were, a septum which in time, as the patient gets older, is forced by the blood stream into a nipple-like projection with a tiny hole in its summit. It projects into the pulmonary artery much as the cervix projects into the vagina. Its formation and structure show at a glance that it is eminently suitable for relief by division: moreover, a much larger hole could be made in a very short time, in exactly the right place, if it is possible with the Blalock operation, in which a long tedious dissection is necessary to secure a systemic anastomosis of adequate size.

Before attempting to relieve a valvular stenosis clearly desirable first to diagnose its presence. This diagnosis should consist of a pre-operative assessment by physical and various accessory methods and an actual assessment at operation. This is not the place to enter upon the problem of pre-operative diagnosis, which will be dealt with in a later communication.

A great deal can be learned at operation, although experience is as yet too limited for dogmatism. Time further experience can alone provide greater efficiency; present it must suffice to say that much can be learned from direct cardiac examination.

Direct Cardiac Examination at Operation

One disadvantage of the Blalock operation, especially if it is done from the right-hand side, is that only very little examination of the heart is made. In most cases all that is done is that the great vessels are exposed, dissected and an anastomosis performed. The completeness of pre-operative diagnosis can only be assumed, unless the patient dies and the heart can be inspected.

Clearly the best way to assess the state of the valves is to inspect them under direct vision. This formed the problem that was dealt with. A cardioscope to allow inspection of the interior of the heart was designed and described by Allen and Graham (1922); the principle of contact visualization is used in which the blood is displaced and the instrument rests directly upon the structure to be viewed. Using an operating cardioscope constructed for me by Mr. Schrantz, of the Genito-Urinary Manufacturing Company, with his usual superb skill, I have made a number of direct inspections in living patients.

One problem is the route of cardioscopy. Passing the instrument through the ventricular wall has apparent disadvantages that an alternative was sought. Study of the anatomy suggested the possibility of using the left pulmonary artery, for this structure normally provides a direct line with the main pulmonary trunk and provides a direct route to the valves. Left pneumonectomy provided excellent opportunities to test this, and it has been shown to be a practical procedure. The instrument can be passed without difficulty and the valves inspected although the vision in a normal patient is naturally limited by the constant movement of the cusps.

JUNE 12, 1948

VALVULOTOMY FOR PULMONARY STENOSIS

The first patient with congenital pulmonary stenosis, a young man of 17, was operated upon in May, 1947. The chest was opened through a left postero-lateral incision, as this approach is necessary in order to introduce the straight instrument into the heart. The valves were inspected and were seen to be normal; the stenosis was clearly subvalvular. A Blalock operation was performed by anastomosing the left subclavian artery to the left pulmonary artery, using the hole made for the passage of the cardioscope. The whole procedure meant that the pulmonary artery was occluded for a very much longer time than is usual in the Blalock operation, and this was largely responsible for the patient's death 12 hours later. Necropsy confirmed the presence of a Fallot's tetralogy with a severe infundibular stenosis and normal valves.

The next patient, a girl of 19, sent to me by Dr. East, was diagnosed pre-operatively as having a pure pulmonary valvular stenosis; the heart was very large, chiefly due to hypertrophy of the right ventricle. At operation in November, 1947, the pulmonary artery was found to be very small and, owing to the great size of the right ventricle, which had caused gross dilatation, it arose from the main trunk at a right-angle so that it was not possible to pass the cardioscope. Neither was it possible to perform a Blalock operation. No ill effect followed the operation. The patient died of heart failure several months later and, most unfortunately, no post-mortem examination could be made.

A third patient, a girl aged 20, had severe pulmonary stenosis which was diagnosed clinically as being of a pure valvular type. She had had several attacks of heart failure, had gross albuminuria and oedema, and had a very large heart. She was considered unsuitable for operation, but at the express entreaty of herself, her parents, and her doctor it was agreed to make the attempt. A left postero-lateral thoracotomy was done, the pericardium was opened to permit more direct examination of the heart as in the other cases, and a confident diagnosis of valvular stenosis was made. A short pause was made while the operating cardioscope was assembled, and when one turned again to the heart it was found to have stopped. It was eventually started again by massage and injection of adrenaline, but gradually failed again. It was again revived and again began to fail. It was decided to perform cardioscopy; the instrument was passed and the presence of a diaphragmatic valvular obstruction of characteristic nipple-like shape was easily observed. The heart, however, had again stopped and could not be revived. Necropsy confirmed a pure valvular stenosis with an almost pin-hole orifice of such minute size that it was astonishing that she could have supported life for so many years; very gross hepatic cirrhosis was present from back-pressure; the kidneys showed similar gross changes from chronic passive congestion.

From the experience of these cases, and in particular of the last one, it was felt that the approach through the left pulmonary artery was unsatisfactory, or at any rate was sufficiently unsatisfactory to be discarded for the time being in order to assay the ventricular route. It is clear that in certain of these patients with a valvular stenosis occlusion of the left pulmonary artery for even a short time may not be tolerated; in addition it was felt that the conical shape of the valve made rapid and precise division from above uncertain. These experiences with three patients had shown, however, that it was possible to diagnose pulmonary valvular stenosis with some degree of confidence at operation.

In addition to direct inspection of the valves much other valuable and significant information can be obtained by direct critical external examination of the heart. Even before the pericardium is opened a tentative diagnosis can be made. When a valvular stenosis is present the stem of the pulmonary artery immediately distal to the obstruction is often dilated and forms a thin-walled aneurysm-like bulge; this can be seen through the intact pericardium and a thrill of characteristic nature can be readily felt. If the pericardium is opened a much more useful examination can be made. The sac should be incised longitudinally for

some 5-8 cm. just anterior to the phrenic nerve, and by means of an additional transverse incision at each end a flap is turned forwards: by grasping the corners of this flap with haemostats it is also possible to manipulate the heart. Attention should first be directed to the region of the sinuses of Valsalva: if the sinuses are present and fully formed it is almost certain that the valve cusps are normal. Conversely, when a valvular stenosis is present there is either a continuous collar of dilated artery just above the valve-level, or the artery shows a larger, aneurysm-like dilatation resembling the bulb-like swelling of a young onion. The lesser degree of dilatation is usually associated with a smaller pulmonary artery of lower tension, and I suspect that it implies the existence of a subvalvular stenosis as well, although as yet insufficient observations have been made to confirm this. The greater degree of dilatation suggests a more powerful jet of blood coming through the stenosis. Palpation of the first part of the artery is most suggestive of this: the thrill is quite characteristic, and of a fine high-pitched frequency, very strictly localized at a level just above the origin of the artery, and, most significant of all, can actually be felt to be extremely localized within the central portion of the lumen. Indeed, it feels as if it were caused by a thin but very powerful jet of fluid being forced through a tiny hole, and this is exactly how it is formed. If the thin-walled dilated artery is gently compressed between the fingers the precise, localized nature of the thrill becomes more obvious, and it is even possible to feel the conical valve momentarily between each heart-beat. If the finger is now passed down on to the surface of the right ventricle it will be found that the fine, purring thrill rapidly fades.

When a subvalvular stenosis is present no such characteristic localized thrill is felt in the first part of the pulmonary artery. The thrill is coarser, as if of a lower frequency, and although it can be felt by a finger placed on the artery this is because it is conducted towards it. It is felt more strongly just below the level of the valves, and altogether its localization is less precise. It is felt over a somewhat wider area. The infundibulum may also present as a thin-walled, aneurysm-like dilatation with a coarse thrill palpable at its base and conducted distally along the pulmonary arteries. Further information should be obtainable by means of direct pressure readings at different levels, but so far this has not been done successfully on the unopened heart.

Direct external examination of the heart in this way, coupled with pre-operative assessment, should provide enough information to decide whether a valvular stenosis exists.

The final observation should be direct valvulotomy through the wall of the ventricle, and it is intended to do this. It had been planned in the three cases next to be described, but at the actual operation it was felt to be wiser to omit it, chiefly on account of the uncertainty of how the heart would tolerate the extra manoeuvre. It is, after all, a serious and anxious step to perform a cardiectomy, and until one is more familiar with what these abnormal hearts will tolerate in the way of manipulation and interference it seems wiser to proceed cautiously step by step. With an operation of this sort one makes certain plans beforehand, but in the tension of the most critical phase of the operation it may be found easier not to attempt too much. It is nevertheless definitely desirable to include direct cardioscopy in the operative assessment.

Although the cardioscope is provided with a cutting knife which can be advanced under direct vision it was decided to use a special valvulotome for division of the stenosed valve in these first cases. This enables the stenosis

to be located and divided almost instantaneously, whereas the operating cardioscope might well entail considerable fumbling and uncertainty. The valvulotome used has a gently curved shaft ending in a blade shaped like a spear-head and carrying a short probe-end; the two edges proximal to the probe-end are cutting; the shoulders and the retreating edges are blunt. This instrument was also made for me by Mr. Schrantz. A pair of gently curved dilating forceps with fine blades, rather like a curved sinus forceps, are also used after the valvulotome.

Case 1

Miss D. N., aged 18, had been cyanosed from birth. She walked and talked at a normal age, but always had great disability in getting about, and during the winter could not walk at all outside the house; in the summer, unless it was too hot, she could sometimes walk as much as 200 to 300 yards, although in recent years she could rarely manage more than 50 yards. She squatted as soon as she learnt to walk, and continued the habit when older, although her mother tried to stop it. She found that nothing relieved her discomfort so quickly after walking, and needed to do this in the x-ray room after feeling exhausted when standing up for screening.

Her cyanosis was fairly severe, Grade III, though it did get less with complete rest on a warm day. It would get worse with emotion as well as with exertion, and was changed greatly by a minor effort like undressing. The nails showed Grade III clubbing. She had fairly severe cyanotic attacks as a child after feeding; and at 15 she spent a period of many months in bed, when her colour was exceptionally bad and her doctor thought she was not likely to survive.

The heart was not enlarged; there was a rough systolic murmur down the left side, loudest in the pulmonary area, and a faint systolic thrill; the pulmonary second sound was faint. Screening showed clear lung fields, a left-sided aorta, and no increased pulsation in the lung roots; the heart was not generally enlarged. Electrocardiograms revealed extreme right ventricular preponderance. Blood pressure was 110/85. A blood count showed red cells, 7,400,000; Hb, 127%. The arterial oxygen saturation at rest (Dr. Zak) was 90.9%.

A diagnosis of Fallot's tetralogy was made.

Operation (Feb. 16, 1948)

Intratracheal cyclopropane was given by Dr. E. H. Rink, and an intravenous infusion of plasma (one bottle) was administered. A left inframammary incision was made and the chest was opened through the second left interspace with division of the second costal cartilage; many collateral vessels were met with. As soon as the chest was opened the heart's action became very feeble and slow—less than 50; the general condition was poor and gave considerable anxiety. The left pulmonary artery was small, thin walled, and of low tension, and the anaesthetist felt that the patient would not tolerate its occlusion for a Blalock operation.

Palpation of the pulmonary artery area revealed a thrill suggestive of a valvular stenosis. The pericardium was opened and the pulmonary artery was seen to be slightly dilated in its first part and showed no sinuses of Valsalva. The thrill was of a thrilike character and was situated exactly in the position of the pulmonary valves; moreover, what appeared to be a single valve could be felt through the vessel wall. No thrill could be felt lower down. It was decided to perform valvulotomy.

Three or four of three interlocking mattress sutures of linen were inserted in the wall of the right ventricle, which was then pulled out between them; the pressure within the ventricle was 24 cm. of saline. The wall was 1.25 cm. thick. The mattress sutures were crossed and held by an assistant so as to pull the heart out from the incision. The curved valvulotome was inserted and passed effortlessly into the pulmonary artery, and the valve was then passed and opened fully. The heart was then pushed and opened fully. The heart's four valves were closed by two mattress sutures each, and the pericardium sown to it; the chest was closed and the patient given 10% glucose solution.

The thrill persisted, but its character changed from a fine jet-like nature to a coarser one of lower frequency; the pulse-wave could be clearly seen within the pulmonary artery. The colour was poor at the end of the operation in spite of a good respiratory exchange.

Post-operative Course

The patient's condition was grave after the operation and her colour was bad even with oxygen. She showed little improvement until Feb. 20, when her colour was better and her blood pressure had slowly risen to 120/80. The heart was very large on Feb. 18, suggesting grave dilatation, possibly due to profound alteration in mechanics; it was much smaller by Feb. 21 and her colour had improved further. A systolic murmur could still be heard.

She made steady improvement as regards her heart, but on the evening of Feb. 24 she complained of sudden severe pain in both legs with loss of movement and sensation. Unfortunately the full significance of this was not appreciated, and I was not informed until more than 24 hours later. By this time the right leg had improved, but the left leg was cold, pulseless, pale, painful, and insensitive. It was clear that an arterial occlusion was present, probably embolic, but it was considered to be too late to justify exploration. Further improvement occurred in the legs, and all peripheral pulses could be felt on the right but not on the left. Two or three superficial ulcers appeared around the left ankle; these have since healed. The condition of the legs delayed her getting up, but her colour remained good except for occasional mild cyanosis with emotion and when she first began to get out of bed. She was allowed home on March 18, at which time her red cell count was 6,200,000, Hb 119%, and arterial oxygen saturation 79.6%.

She was seen on April 10 and had made good progress. There was no cyanosis, the finger-nails were pink, and she walked about the room without dyspnoea although there was a slight suggestion of cyanosis. She no longer squats. Her relatives are most emphatic that the relief of cyanosis and of dyspnoea is impressive. They emphasize especially the absence of dyspnoea, which had always been a marked feature even at rest.

Comment.—It is as yet too early to assess the results of operation completely in this case. The condition of the left leg has prevented full test of activity. It would appear that a sharp watch must be kept in these cases for symptoms suggesting arterial embolism and prompt action taken. There has been definite improvement in the cardiac condition, although less than hoped for. The prognosis in these older patients is less certain, and from her behaviour under anaesthesia she might not have tolerated a Blalock's operation. She would appear to be an example of Fallot's tetralogy with a valvular stenosis, although probably some degree of subvalvular stenosis exists as well.

Case 2

Gwenda B., aged 11, the youngest of eight children, had been obviously cyanosed at 6 months, though blue lips had been noted before this. She walked at 1 year and squatted as soon as she walked; she was never able to walk more than 100 yards without distress, although she could sometimes manage as much as half a mile by getting very breathless. Cyanosis was extreme, ranging from Grade III to Grade IV; the fingers showed Grade III clubbing. She was well developed physically and could walk about the ward without getting breathless.

The heart was sabot-shaped, with the apex raised off the diaphragm. The aorta was right-sided. A faint thrill was felt in the pulmonary area on one occasion; a loud systolic murmur was maximum in the pulmonary area and widely conducted. The blood pressure was 95/65; electrocardiograms showed gross right ventricular preponderance. The lung fields were clear and there was no pulsation. Red cells, 8,700,000; Hb, 156%; haematocrit, 77.5%.

A diagnosis of Fallot's tetralogy was made.

VALVULOTOMY FOR PULMONARY STENOSIS

Operation (Feb. 19, 1948)

Intratracheal cyclopropane was given by Dr. Helliwell, and one bottle of plasma was infused intravenously. A left inframammary incision was made and the chest was opened through the second left intercostal space with division of the second costal cartilage. There were numerous collateral vessels; the left pulmonary artery was small. The pericardium was opened and the main pulmonary artery was also found to be small, being about 1.25 cm. in diameter; it was of low tension and there were no sinuses of Valsalva. A fine faint thrill could be felt in the position of the valves but not in the subvalvular position. After some deliberation it was decided to perform valvulotomy.

The right ventricle was opened and the valvulotome passed: it met with definite resistance at the valves, and slight pressure carried it into the pulmonary artery; dilating forceps were passed and opened widely. Free bleeding occurred from the heart, and during manipulations the pulse became poor in quality but soon improved. The cardiectomy incision was closed with four sutures; the pericardium was sewn down over the suture line. The general condition was fair, although the colour was poor: it had been poor at the beginning of the operation. The blood pressure was 85/55, as opposed to 90/60 at the beginning.

Post-operative Course

The patient was very blue, even in the oxygen tent, for the first 24 hours; her colour then began to improve very slowly but steadily, and by Feb. 27 was reasonably good. Her progress was then rapid, and in fact by March 1 she was out of bed and visited the next ward, where she sat at table for a birthday party with other children without any distress. She was very soon able to walk freely about the ward and even down to the x-ray department, and maintained her good pink colour. This was in marked contrast to her constant cyanosis before operation. The arterial oxygen saturation (March 21) was 81%, but she was crying and distressed during the arterial puncture.

She was discharged home on March 25, the blood count at that time being: red cells, 6 millions; Hb. 116%; haematocrit, 56. She had ceased to squat.

She was seen on June 4 when she looked well and was a good colour; her mother said that her exercise tolerance was greatly improved and she was now able to run, a thing she could never do before the operation. The mother particularly remarked upon the normal colour of the nails, which had always been blue. The child walked normally to the x-ray department for screening, but although she showed no dyspnoea a slight tinge of cyanosis could be seen in the cheeks. This is not uncommon on exercise after a successful Blalock operation.

Comment—This would appear to be a case of Fallot's tetralogy with a valvular stenosis; the hypoplasia of the pulmonary artery strongly suggests that a degree of subvalvular stenosis is present as well. Nevertheless, the result of valvulotomy has been most encouraging. The colour and clinical improvement are as good as after a successful Blalock operation.

Case 3

Miss R. C., aged 23, had been cyanosed since birth and did not walk until 3 years old. She was never allowed to go to school and dyspnoea had always been extreme. As a child she was able to play with other children, but had to rest frequently by squatting. She has always squatted, and even sleeps prepped up with her legs curled up. Until the age of 18 she was able to walk perhaps 50 yards without stopping and could go considerably further with frequent rests. About five years ago, however, she became much worse quite suddenly, and found she could do very little without extreme distress. In fact, until October, 1947, she remained almost wholly in bed or on a couch, moving only from bedroom to sitting-room; any effort, even moving in bed, provoked dyspnoea and pain across the chest. In October, 1947, she spent five weeks in the National Heart Hospital, and with encouragement found she was able to do a little more; for instance, she could just about walk the length of the ward and could sit up for meals.

She was poorly covered; finger clubbing was Grade I and cyanosis Grade I (i.e., not cyanosed at rest in bed): there was

extreme dyspnoea with rapidly developing cyanosis on walking; the blood pressure was 115/70. The heart was not enlarged, although the apex was raised a considerable distance from the diaphragm, suggesting right ventricular hypertrophy; a definite rounded shadow in the region of the "census" suggested a minor degree of aneurysmal dilatation of the pulmonary artery. Perhaps a slight thrill could be felt in the pulmonary area; a harsh systolic murmur, loudest in the pulmonary area, was audible all over the praecordium and also at the back of the left chest. On screening, the lung fields were clear and showed no pulsation. Red cells, 6,500,000; Hb. 128%; haematocrit, 56. Circulation time (Dr. Allant): arm to tongue, 10.5 seconds; arm to lung, 8.4 seconds (indicates right to left shunt).

Cardiac catheterization (Drs. Zak and Hollings): pressure in right ventricle, 53 mm. Hg; pressure in pulmonary artery, 12 mm. Hg. Oxygen saturation in superior vena cava, 56%; in right pulmonary artery, 67%; in femoral artery, 77%. This was taken to indicate pulmonary stenosis with a right to left shunt.

A diagnosis of Fallot's tetralogy was made, although the presence of an associated valvular stenosis was considered probable.

Operation (March 23, 1948)

Intratracheal cyclopropane was given by Dr. Helliwell. Two bottles of plasma were infused, followed by one bottle of blood. A left inframammary incision was made and the chest opened through the second interspace, with later division of the second and third costal cartilages; a considerable number of collateral vessels were encountered.

As soon as the heart was exposed the smooth globular dilatation of the pulmonary artery within the pericardium was seen; a fine jetlike thrill could also be felt. The pericardium was opened, the pulmonary artery was now seen to be dilated to a diameter of about 2.5 cm. and was thin-walled, with dark blood easily seen through it. The artery beyond the dilatation was 1.5 cm. in diameter. There were no sinuses of Valsalva. Careful palpation again confirmed the jetlike nature of the thrill, which seemed to arise from the level of the valves; moreover, at times it seemed as if one could actually see the white cone of the valvular stenosis through the thin wall.

In addition to applying swabs wet with procaine solution to the heart 1 ml. was injected into the wall of the ventricle. A double row of mattress sutures was inserted and a small incision made to allow a curved cannula to be introduced. The pressure in the ventricle was only 5 cm. of saline, and was the same in the pulmonary artery; it was felt that this low pressure was the result of manipulation of the heart. A probe 3 mm. in diameter was now passed into the ventricle, and was felt to catch on the valves, suggesting a diaphragmatic stenosis. It was decided not to pass a cardioscope in view of the low blood pressure.

The valvulotome was now inserted, and was felt to catch on the valves and then to pass on into the pulmonary artery. After a pause the valves were further dilated with forceps. A pressure reading was again taken; this showed a mean of 15 cm. of saline in both the ventricle and the pulmonary artery, with obvious fluctuation in systole and diastole. The incision was now closed with three mattress sutures; the pericardium was not sewn to it.

The general condition at the end of the operation was satisfactory; the systolic blood pressure was 70 mm. Hg.

Post-operative Course

Although the patient began to come round at the end of the operation she became very drowsy the same evening, and on the next morning was still drowsy and had a complete left-sided hemiplegia. She was slightly blue even in the oxygen tent. Dr. McArdle, who saw her, thought the hemiplegia might be due to an embolism rather than to thrombosis.

Her general condition steadily improved and her colour became and remained a good pink. The paralysis showed no sign of improvement for over three weeks. By April 22 she was able to move the upper arm, elbow, hip, and knee, but hand and foot movements were still absent. At that time she was up most of the day in a chair with no distress. Red cells,

4,000,000; Hb, 92; haematocrit, 48. On April 27 arterial oxygen saturation was 88.5%.

Comment.—There seems little doubt that there has been considerable improvement in the cardiac condition, and the fall in blood count and haematocrit reading (both of which are now normal) and the rise in the oxygen saturation percentage are most encouraging. Unfortunately the persistence of the hemiplegia makes it impossible to assess the actual functional improvement. It is thought that the paralytic will soon improve enough to allow the patient to move about by herself.

Conclusion

These three cases are by no means precise, but the results are considered to be encouraging enough to be recorded in this preliminary communication. They serve, at any rate, to show that pulmonary valvulotomy is a feasible operation, and all three patients have survived the procedure. The result in the first may be classed as moderately successful so far; in the second the result is good; in the third it would appear to be good, but is as yet indeterminate functionally.

Two of the patients were of an age when the prognosis is ordinarily poor and when any operation carries a grave risk, both were very severely disabled. There can be no doubt that far better results are to be anticipated in younger patients, but it has not yet been possible to extend the operation to the younger age groups, although it is intended to do so.

The vascular complications in the first and third cases are disturbing and disappointing. The first case teaches

that a careful watch must be kept for signs of peripheral arterial embolism after cardiomy so that immediate amputation can be considered. Arterial thrombosis, even to the extent of hemiplegia, occurs with the Blalock operation just as often. Presumably it is most likely to occur when the blood pressure falls to a low figure for some time, especially in the presence of polycythaemia.

Much still remains to be done in the development of this operation in the treatment of "blue children" suffering from pulmonary stenosis, but the results in these three cases are encouraging enough to justify proceeding further with it. It should be made clear that it is not suggested that this operation is meant to supplant the Blalock operation. As it stands at present it is of use in only a small proportion of cases, until a method can be found to relieve the subvalvular stenosis (if indeed this is possible), the Blalock operation must continue to take precedence. However, unless the Blalock operation is considered to have solved the problem of *morbus caeruleus* completely, it is essential to try to develop new and alternative measures.

I am indebted to Dr. Maurice Campbell, under whose care all the patients were, for most of the case histories, which are made available here.

B.C.G. VACCINATION: IS IT OF ANY VALUE IN CONTROL OF TUBERCULOSIS?

BY

ARVID WALLGREN, M.D.

Professor of Paediatrics, Royal Caroline Medical Institute, Stockholm, Sweden

Several eminent German physicians who are about to introduce B.C.G. vaccination in Germany, thanks to the Scandinavian Red Cross, have called my attention to the article on this subject contributed to the *British Medical Journal* by Dr. G. S. Wilson (1947). From various quarters, including England, I have been requested to answer his criticism of B.C.G. vaccination, which has given rise to a certain hesitation and concern, since Dr. Wilson, as a member of the Medical Research Council, is a critic whose opinion carries considerable weight. As I introduced the most widely practised and, by Wilson, criticized method of B.C.G. vaccination and am largely responsible for its present widespread use in Sweden, and as, furthermore, I am prepared to help in introducing it to combat tuberculosis in the devastated countries of Europe, I feel prompted to test the value of Wilson's criticism.

I have no reason to disbelieve Wilson when he says that he is not prejudiced against B.C.G. vaccination; my faith in his objectivity is, however, put to a severe test by the manner in which he argues against B.C.G. In several points the criticism is undoubtedly justified, although corrected on unessentials; in many respects it is erroneous and unjust, not giving the impression of being sufficiently unbiased; and in all respects it overshoots the mark.

Investigations on Children

Wilson's quotation of my investigation (Wallgren, 1947) is entirely correct; I pointed out in that paper that it was not feasible to establish how large a part B.C.G. immunity had played in the favourable results reported. Other factors were contributory. Although many children were isolated until 3 months of age before being subject to exposure, after this period they nevertheless were exposed to virulent infection without falling ill from primary tuberculosis, save in a single case. This is a result which surely cannot be paralleled when dealing with children of this age if they have not been vaccinated before exposure to infection. Further experience has shown me that cases of clinical tuberculosis occurring after an adequately performed B.C.G. vaccination are extremely uncommon and remarkably benign. While primary pulmonary tuberculosis in a child unvaccinated with B.C.G. does not show any tendency towards radiographically demonstrable regression during the first six months, in a child who has been vaccinated with B.C.G. and who was still tuberculin-positive at the time of infection radiographs reveal that within this period the infection has virtually resolved. It is also remarkable that I have not seen a single adequately vaccinated child die from tuberculosis after having been infected, nor have I observed a single case of tuberculous meningitis among vaccinated children. Is, then, the scientifically calculated and statistically reported degree of immunity of such great importance if the effect of the vaccination is satisfactory?

Rosenthal and his co-workers (1945) have used a different method of vaccination (multiple punctures) from that which I have had experience (intradermal). Wilson is admittedly right in stating that the results of their ex-

diseases. They certainly are not so in our country. The prevention of clinical primary tuberculosis or pleurisy means a very great gain: children do not have to give up school for a period of three to six months or more; and adolescents and adults avoid unemployment because of illness during an equally protracted period, besides being subject to less risk of post-primary tuberculosis. This is perhaps the most demonstrable effect of the immunity conferred by B.C.G. vaccination. Therefore if one claims to give an unbiased and comprehensive evaluation of the effect of B.C.G. vaccination it is not fair to exclude these cases.

The fact that B.C.G. vaccination is particularly effective against the immediate dangers of virulent infection in the tuberculin-negative induced Heimbeck, in his group of pupil nurses, to transfer those who originally belonged to the tuberculin-negative group to the tuberculin-positive group a year after virulent infection. This has been criticized by Wilson, who claims that all the nurses should have remained in the group to which they belonged at the beginning of the study. Heimbeck (1947) publishes a table of his results with B.C.G. vaccination of pupil nurses during their three years' training: every nurse remains in the group in which she started at the beginning of her training period. He adds that these pupil nurses lived under exactly the same conditions, and that all of them were exposed to the same risk of contamination during training. The three groups were from the same period. It seems to me that this comparison thus fulfils Wilson's claim, and still the difference between the B.C.G.-vaccinated (morbidity 24.1, mortality 2.1 per 1,000 observation years) and the unvaccinated tuberculin-negative group (morbidity 141.2, mortality 14.6 per 1,000 observation years) is striking.

Alleged Difficulties and Disadvantages

The difficulties and disadvantages that the use of B.C.G. might entail are enumerated in seven points by Wilson. Let us discuss these alleged disadvantages.

1 *B.C.G. is a live vaccine that demands great care in preparation to avoid contaminants and must be used within one week.*—Is it not also necessary to exercise great care in the preparation of smallpox vaccine and therapeutic sera? B.C.G. has been used with success after the lapse of 10 to 14 days and this does not necessarily have to be used exclusively during the first week after preparation, although this is preferable.

2 *The virulence of B.C.G. is not fixed.*—This is correct and is also true of smallpox vaccine, but the virulence of B.C.G. vaccine from one and the same laboratory varies only slightly and never suddenly, and it is tested continuously. There is no risk of a B.C.G. vaccine becoming so virulent that it induces frank abscesses in all individuals. That this alleged disadvantage is negligible is shown by the fact that the dosage of the B.C.G. vaccine prepared in Sweden (0.05 mg.) is the same now as it was 20 years ago, and that throughout this period it has remained constant. A factor that varies, however, is the individual response to the vaccine. In a subject with a low resistance abscess formation may occur, but with a high resistance the same vaccine may not induce any reaction whatsoever. It is not very likely that B.C.G. resistance in the individual is parallel with his resistance against virulent tubercle bacilli, and therefore, notwithstanding the abscess formation, it must be regarded as beneficial and fortunate for the person with a low resistance that he is vaccinated with B.C.G. The person with a low resistance has perhaps did not acquire any specific immunity, but he has better prospects though lacking

extremely seldom we see any serious ulceration, and still more rare is the occurrence of a swelling of the regional lymph glands. Törnell (1947) found a local reaction of 10 by 10 mm. in only 2.8%. The slight ulceration that very commonly occurs is of no consequence. If the inoculation gave rise to distressing local reactions it is hardly likely that in Sweden tens of thousands of mothers annually would of their own initiative bring their children to the doctors to have them vaccinated with B.C.G. At any rate, they have from personal experience come to consider these local discomforts trivial in comparison with the benefit conferred by inoculation.

4 and 5. *Infants of tuberculous mothers must be separated at birth until B.C.G. vaccination has produced tuberculin sensitivity, or, if taken away after exposure, they must be separated for at least six weeks before inoculation.*—This cannot be a disadvantage exclusively confined to B.C.G. Does any physician of our day permit a tuberculin-negative infant or a child to remain in an infectious home in the presence of a case of open tuberculosis if there is any possibility of segregating it? In our country this would be branded as almost criminal and would undoubtedly lead to an admonition from the Medical Board. The difference between the B.C.G.-vaccinated children and non-vaccinated children is that the former may return to their infectious homes when the vaccination has taken, while the non-vaccinated must stay away while the source of infection remains. This curtailment of the period of isolation we in Sweden consider rather as one of the advantages of vaccination with B.C.G.

6. *Infants separated and kept in residential nurseries may be exposed to serious risk of cross-infection and die.*—May I ask: Is it less dangerous to keep the infant in its home and let it become infected with virulent tubercle bacilli? Are not the infants even now, before the introduction of B.C.G. vaccination in England, separated from their infectious surroundings, and if so, where and in what way are they cared for? Is the risk for an infant separated in order to be vaccinated with B.C.G. greater than for infants separated from their dangerous home without being vaccinated? I should think that the danger is greater in the latter, because the period of separation must certainly be much longer than the few months in the case of a vaccinated child. Out of 117 infants who were vaccinated at birth in 1928-33 and who at the follow-up examination in 1934 were at least 1 year old, only four had died during their first year of life. These infants were segregated in a nursery from birth until they were a few months old. These figures do not indicate that separation for B.C.G. vaccination, when carried out under satisfactory conditions, constitutes any great danger for the child.

7. *It is desirable to revaccinate at intervals in order to ensure the continuance of immunity.*—This is of course a drawback. In Sweden revaccination is not commonly done. The tuberculin-sensitivity has a duration of three, five, or ten years or more, and probably the immunity continues as long, perhaps even longer. At any rate, the protection has lasted during the most susceptible childhood ages, even if revaccination is not carried out at the end of the tuberculin sensitivity.

In this discussion I hope that Wilson's seven points have been judged according to their deserts.

Conclusion

Wilson shoulders a great responsibility when he endeavours to decrease the interest in B.C.G. vaccination and to discourage its introduction into his own country. Although he cautiously enough concludes by recommending experiments with B.C.G. vaccination in specially threatened groups of the population—nurses and physicians—he does not do even this whole-heartedly, seeing that he at the same time tries to depreciate the danger menacing these same groups, thus intimating the superfluity of such an experiment. It seems as though he were in fear of an unbiased trial, while we who uphold B.C.G. vaccination know that to make an adequate trial with B.C.G. is automatically to become an adherent of the method. The erroneous conclusions drawn by Wilson from cited statistical reports with reference to the danger of

tuberculosis in England have already been taken up in an editorial comment in the issue of the *British Medical Journal* in which his article appears. I therefore need not enter upon this subject.

Wilson does not stand alone in criticizing B.C.G. vaccination. I myself, 20 years ago, strongly censured the manner in which B.C.G. vaccination was then carried out, as well as the conclusions drawn (Wallgren, 1927); but later, when it was performed in a satisfactory way, I became a fervent supporter of the method. Levine and Sackett have expressed very strong opinions on the B.C.G. studies of other workers, but Wilson does not accept the work even of these authors, as the vaccinations were carried out without consideration of the fact that protection does not arise until the vaccine has taken. These two B.C.G. opponents had finally to admit that if they comply with that condition the mortality among the non-vaccinated infants is three times greater than that of the vaccinated infants; how many times greater then is the morbidity, of which one does not receive any information? Aronson and Palmer were rather sceptical with regard to B.C.G. when they undertook their investigation, intended to demonstrate whether B.C.G. had any effect. They learned by experience that B.C.G. satisfies even rather large demands as a protective measure. I am confident that Wilson also, if he really is willing to perform adequate investigations with B.C.G. under scientifically unimpeachable conditions, will by degrees come to be a protagonist of this method of vaccination.

THE EFFICACY OF B.C.G. VACCINATION

BY

H. MALMROS, M.D.

Physician-in-chief, Central Hospital, Örebro, Sweden

Last year hundreds of thousands of young children and adolescents in war-ravaged Europe were tuberculin-tested and the non-reactors vaccinated against tuberculosis with B.C.G. This extensive campaign, which was initiated and financially sponsored by the Danish Red Cross Society, does not appear to be very well motivated if B.C.G. vaccination does not confer an increased protection against tuberculosis. According to Prof. G. S. Wilson (1947) the value of B.C.G. vaccination is rather problematic and in any case not definitely proved.

Difficulty of Procuring Control Material

The great difficulty in getting fully comparable control material is the reason why there is still debate about the efficacy of a prophylactic measure which has been in use for many years. In his famous novel *Martin Arrowsmith* Sinclair Lewis describes the difficulties met with when a scientific experiment is consistently conducted with living human beings as objects and alternate patients are taken as controls. Where mass investigations are concerned,

which require a certain amount of propaganda to induce the public to take active part, it is soon found to be impossible to treat only every other person. There will be letters to the daily press from agitated members of the community who have been refused permission to share in the new medical discovery. If it be announced that the method is still uncertain and must first be tested, the rumour arises that it is something dangerous. The result will be that only a small proportion of the public will volunteer, and hence, statistically viewed, the material will be to some extent a selected one. Nor is it possible in our modern community to inject sterile saline instead of vaccine into every alternate subject without publicly giving notice of this from the outset. Should such a measure be adopted in secret, the whole investigation would immediately become discredited when the first cases of disease appeared among those who had received only a simulated vaccination.

The difficulties enumerated here have been so great that at all centres in Scandinavia where the Calmette method has been used it has been considered necessary to abandon the statistically most trustworthy method of vaccinating alternate cases.

Primary Infection at Adult Age

How, then, has B.C.G. vaccination become so popular in Scandinavia without definite proof of its reliability? First we are convinced that pulmonary tuberculosis is nowadays very often a direct consequence of primary infection in adults (Heimbeck, 1928, 1929, 1936; Arborelius, 1930; Kristenson, 1932, 1933, 1942; Malmros and Hedvall, 1938, 1940; Törnell, 1939; Lstvedt, 1932; Frostad, 1944; S. Holm, 1947, and others). Consecutive tuberculin-testing has perhaps been used to a greater extent in Scandinavia than elsewhere, and we have been able to observe continually that previously Mantoux-negative adolescents fall ill with tuberculosis. Sometimes the primary infection produces symptoms similar to those of influenza or a "heavy cold." As a rule the radiographs then disclose a primary focus in the lung and enlarged hilar glands. In other cases it may have its onset as pleural effusion. Often, however, it initially runs an entirely symptomless course. In some of these cases, and in many of those that have had an initial fever or pleural effusion, the first radiographic lung changes that can be classed as genuine pulmonary tuberculosis appear some months later. Malmros and Hedvall showed that genuine progressive pulmonary tuberculosis often begins in these cases as small cloudy spots in the supraclavicular part of the lung or in the first intercostal space (subprimary initial foci). According to Heimbeck, Frostad, Hedvall (1946), and S. Holm, pulmonary tuberculosis can develop in some cases direct from the primary focus by progression out into the surrounding lung tissues or by liquefaction of the primary focus. The last-named has shown that no less than 34% of the cases that exhibit x-ray changes at the primary infection will later develop into genuine pulmonary tuberculosis.

Systematic tuberculin tests carried out before the onset of the disease—e.g., on probationer nurses and medical students—proved that those who were formerly tuberculin-negative were more liable to succumb. Some had relatively mild changes, others became seriously ill, and some cases were fatal. Heimbeck showed that a positive tuberculin reaction can be produced by B.C.G. vaccination, and it was a quite natural step to make an attempt to protect these tuberculin-negative adolescents by means of vaccination. Experience of the past few years seems to confirm the assumption that B.C.G. vaccination confers a certain amount of protection. Very few cases of tuberculosis have been observed among the vaccinated.

Personal Tests With B.C.G.

Since 1942 B.C.G. vaccination has been used to a great extent in Oerebro. The district covers an administrative area with about 230,000 inhabitants. Practically all the newborn are vaccinated. The whole population is successively and systematically tuberculin-tested and the non-reactors are vaccinated if they give their consent. So far, 22,413 persons have been vaccinated, 8,040 being newborn infants, 7,834 children over 1 year, and 6,537 adults. Within the district there are two tuberculosis sanatoria, one central hospital with medical and paediatric departments, and some smaller hospitals. When a case is admitted to any hospital with the diagnosis of tuberculosis or suspected tuberculosis it is ascertained whether the patient has been vaccinated with B.C.G. By this means it is possible to find out whether any of those vaccinated have developed tuberculosis. During the period 1942-7 only one such case has been discovered. This case is of special interest, and a brief report of it follows.

A probationer nurse aged 22 was B.C.G.-vaccinated before starting her hospital duties in 1943. A test one month later showed that she reacted very slightly to tuberculin (Mantoux 1:100). In 1944 the tuberculin reaction was checked and found to be negative; she was therefore again B.C.G. vaccinated. After this inoculation the tuberculin reaction was distinctly positive. At a control examination at the end of 1945, just before she was to begin service at a tuberculosis sanatorium, a tuberculin test did not give a definitely positive reaction. On account of shortage of staff, however, the physician allowed her to start work there in spite of her negative reaction. X-ray films showed no pulmonary changes. Two months later she was again tuberculin-tested, and was then found to be a strong reactor. Another x-ray film showed normal conditions. Some months later, however, she developed pleurisy with effusion. *Mycobacterium bacilli* could be demonstrated on culture and inoculation of pleural fluid. She is now healthy again, without x-ray changes in the lungs, and at full work. Nevertheless the case must be interpreted as tuberculosis—up to that time the only one known among 22,000 vaccinated persons. It is obvious that in this case vaccination had not given sufficient resistance. This was doubtless due to a deficient power of reaction.

Other Scandinavian Investigations

My material is certainly large, but the observation period is as yet too short to allow of any definite conclusions regarding the efficacy of B.C.G. vaccination. Investigations from other areas in Scandinavia, however, point in the same direction. In the small Danish island of Bornholm, where, according to Olsen (1943), more than 23% of the population have been vaccinated with B.C.G., the whole situation on the tuberculosis front has altered. As is shown in Graphs 1 and 2, the number of recognized new cases of tuberculosis in the age groups between 15 and 35 years has diminished considerably since B.C.G. vaccination was instituted on a

GRAPH 2.—New cases of pulmonary tuberculosis by age groups, in Bornholm, Denmark, 1941-5; 23% of the population are now B.C.G.-vaccinated.

large scale. It is within these ages that most cases of pulmonary tuberculosis are found. If in other countries, too, an appreciable change in the morbidity curve, with the disappearance of the high peak of pulmonary tuberculosis in the years of adolescence, should be obtained in the course of some ten years, this could be interpreted as a rather tangible manifestation of the efficacy of B.C.G. vaccination. This does not, however, amount to absolute proof, since the reduced number of cases might depend on improved hygiene, fewer bacillus-carriers, and other unknown factors.

An Epidemic of Tuberculosis

Tage V. Hyge (1947) has published a work that would seem to furnish the best evidence hitherto advanced for the efficacy of B.C.G. vaccination. Although it only records a number of cases of tuberculosis at a school, the whole is as clear and unmistakable as if it had been a question of a well-planned laboratory experiment on hundreds of guinea-pigs. The events were briefly as follows.

At a girls' school in Copenhagen a case of pulmonary tuberculosis was discovered among the pupils in October, 1941. This led to a careful examination of all the pupils and the educational staff. In February, 1942, this examination was repeated, with the disclosure on tuberculin tests of 200 non-reactors among the pupils. Of these, 144 volunteered for B.C.G. vaccination. At a new compulsory examination of the whole school in December, 1942, the finding was 130 spontaneously tuberculin-positive, 133 tuberculin-positive after Calmette inoculation, and 105 tuberculin-negative (mainly newly admitted pupils).

In January-February, 1943, there broke out at the school an influenza-like epidemic which closer examination showed to be due to another tuberculous infection. The infection originated from a female teacher who taught in several forms. It was found that among 94 tuberculin-negative pupils who had been exposed to infection 70 had become tuberculin-positive. Of these, 41 had radiographic lung changes, and 37 had bacilli in the gastric lavage. The disease ran a benign course among all the younger pupils. Among those of 16-18 years, however, progressive pulmonary tuberculosis developed in nine cases, this generally starting as subprimary foci of the type described by Malmros and Hedvall. In only two cases did the pulmonary tuberculosis start from a primary focus (in one of these progression did not begin until two years after the infection). In six cases pneumothorax had to be carried out. One of the patients died of pulmonary tuberculosis.

Among 106 B.C.G.-vaccinated who had been exposed to infection there were two cases of pulmonary tuberculosis, and among 105 originally tuberculin-positive there were four cases (only two of these are considered by Hyge to be connected with the infection at the school). It is accordingly clear that B.C.G. vaccination does not, any more than does a tuberculous infection previously passed through, bring absolute protection. Compared with the tuberculin-negative, however, the two categories are in a substantially better position.

GRAPH 1.—New cases of tuberculosis by age groups, in Bornholm, Denmark, 1941-5.

Hyge's investigations clearly indicate the path we must take if we are to combat tuberculosis effectively—B.C.G. vaccination of all tuberculin-negative persons.

Supposed Difficulties and Disadvantages

In his article Wilson also discussed the difficulties and disadvantages which are thought to be involved in the use of B.C.G. vaccination. I fully agree with him when he maintains that very great care has to be taken in the preparation of the vaccine and in its distribution. All B.C.G. vaccine used in Sweden during the past few years has been prepared in a single laboratory and under Dr. A. Wassén's constant supervision. The strain employed for the preparation of the Swedish B.C.G. vaccine was obtained in 1926 from the Pasteur Institute in Paris and has since been kept "active" continuously. In the course of years vaccine has been prepared for hundreds of thousands of vaccinations. In not a single case has it been possible to demonstrate that the attenuated B.C.G. strain has regained its virulence.

Nowadays we are using only the intracutaneous method of injection, which was first proposed by Wallgren (1928). If the injection is made strictly into the superficial layers of the skin large ulcers are very seldom seen. In our series small ulcerations occurred in 11.6% of adults, in 10.4% of children, but in only 2.3% of infants (see Table I).

TABLE I.—Size of Ulceration in the Various Age Groups

Group	No. Vaccinated	Ulcerations			
		Small		Somewhat Larger*	
		No.	%	No.	%
Newborn	8,040	185	2.3	0	0
Children 1-15 years	7,836	816	10.4	126	1.6
Adults	6,537	756	11.6	47	0.7
Total	22,413	1,757	7.8	173	0.8

* Diameter more than 15 mm

The vaccination may very well be left to nurses, who quickly learn the injection technique when they have some practice with sterile sahne.

I tested Birkhaug's needle-puncture method with vaccine twenty times stronger in a small number of cases, but the result was not satisfactory. For instance, of 282 newborn children vaccinated by Birkhaug's method, only 57% were tuberculin-positive on being tested seven to eight weeks afterwards. On the other hand 8,040 newborn babies vaccinated by Wallgren's intracutaneous method with 0.05 mg. of vaccine reacted positively in 94.3% of the cases on being tested six to seven weeks later. Moreover, Birkhaug's apparatus is difficult to sterilize. If it is used for mass vaccination there may be a risk of, for instance, hepatitis virus being transmitted from one patient to another.

As is evident from Table II, the intracutaneous method gives very satisfactory results in newborn infants and older

TABLE II.—Results of Vaccination by the Intracutaneous Method

Group	No. Vaccinated	Tuberculin-Save 6-7 Weeks after Vaccination
Newborn	8,040	94.3%
Children 1-15 years vaccinated at the Central Hospital	2,051	96.8%
Adults vaccinated at the Central Hospital	2,735	93.7%
Adults and children vaccinated in Örebro City	7,475	99.1%

children, as well as in adults, a positive tuberculin reaction being obtained in over 90% in all the groups. Formerly it was thought, on the basis of theoretical speculations, that the newborn would not react so well. As experience now shows that this is not the case, there is no reason to postpone vaccination until a later period. On the contrary,

vaccination immediately after birth has five great advantages: (1) As most children are nowadays born in the lying-in wards of hospitals, this time is the very best if we want to vaccinate as many as possible. (2) There is no necessity for tuberculin-testing the children before vaccination, as all of them are undoubtedly tuberculin-negative at birth. (3) Abscesses very seldom occur in infants. I have never seen any large abscess develop after vaccination of the newborn. Such do occur, however, now and then in older children and in adults. (4) No difficulty is experienced in getting the mothers to allow their newborn babies to be B.C.G. vaccinated. Close upon 100% consent to the procedure. There does not seem to be any risk of B.C.G. vaccination of the babies causing the mothers to be scared of all kinds of protective inoculation. On the contrary, this vaccination is free from pain and gives such slight complications—if it is properly performed—that, if anything, it is a good advertisement for all preventive medicine. (5) After B.C.G. vaccination at infantile age the subsequent tuberculin-testing can be done without risk by the Mantoux method direct with 1 mg.

That infants of tuberculous mothers must be segregated for six to eight weeks after the vaccination can scarcely be ranked as a disadvantage of the method. Every medical officer conscious of his responsibility surely considers it a self-evident duty always to remove the newborn infant from a tuberculous infectious mother quite independently of whether the child has been vaccinated or not. If the child is not vaccinated, this segregation ought to continue until the mother recovers or dies. If the infant has been vaccinated, however, possibly the mother may be allowed to have charge of her child again when the latter has become definitely tuberculin-positive after the vaccination. It is obviously of the greatest importance that the infectiousness of the mothers should be discovered in time. For this reason all prospective mothers should be controlled by miniature radiography. (This procedure has been employed for many years as routine examination of all patients admitted to the Central Hospital.)

It has been claimed that the antibody-producing mechanism is not sufficiently developed in infants and that it would therefore be better to postpone the vaccination to a later point. As this can hardly be experimentally determined in man, one must content oneself with studying the behaviour of the tuberculin reaction. As stated earlier, a positive tuberculin reaction can be produced in the newborn by vaccination with the same dose of vaccine as is used for adults. The reaction becomes positive as early as six weeks afterwards and therefore does not argue in favour of a deficient reactivity. It has not been shown earlier whether the tuberculin reaction remains positive in cases of vaccination immediately after birth as long as in those in which vaccination has been undertaken at an older age. So far as can be judged from our material, however, no difference seems to exist in this respect. The period of observation is admittedly still short, but it seems that those vaccinated immediately after birth retain their positive reaction for several years. Thus, at an investigation of 284 children five years after they had been vaccinated at birth we found 95.1% still tuberculin-positive. By way of comparison it may be mentioned that of 638 children vaccinated at the age of 4 years, 99.2% were still tuberculin-positive on being tested three years later.

What People Ought to be Vaccinated?

The B.C.G. campaign should not by any means be confined to the newborn. Wherever a non-reactor is encountered he ought to be vaccinated. As indicated in Table III, there are also numerous non-reactors in the middle-age

Table III.—*Tuberculin Tests in the Rural Districts of Örebro County*

Age in Years	Non-reactors	Age in Years	Non-reactors
1-5 ..	9%	30-40 ..	11%
6-10 ..	8%	40-50 ..	6%
11-15 ..	8%	50-60 ..	4%
16-20 ..	3%	60-70 ..	4%
21-25 ..	2%	>70 ..	6%
26-30 ..	16%		

groups, especially in the rural districts. The administrative area of Örebro, where these investigations have been conducted, has many big industries and good communications. It is therefore probable that the high number of non-reactors found there is not an exceptional phenomenon but one applicable to many other districts both in Sweden and in other countries. If the B.C.G. vaccination of all non-reactors should meet with organizing difficulties, it could be initially confined to the newborn and to school-children just before the age of puberty. In addition, of course, all medical students, probationer nurses, and other hospital staff ought to be vaccinated, for it has been established by numerous investigations that these fall victims to tuberculosis to a greater extent than others.

Tuberculin Control and Revaccination.—Every vaccinated person ought to be tuberculin-tested six to seven weeks after the vaccination. Should the reaction not be positive, revaccination ought to be done. Later on control should also be undertaken now and then to see whether the tuberculin reaction is still positive, and in case of need vaccination should be repeated. Children vaccinated at birth may be conveniently controlled in the first and the last term at school. Probationer nurses and other hospital staff should be controlled before they start service at a sanatorium or other hospital ward where the risk of infection is particularly great.

Summary and Conclusions

The harmlessness of B.C.G. is established beyond doubt. If Wallgren's method is used and the vaccine in a dose of 0.05 mg. is injected strictly intracutaneously, large abscesses very seldom appear (0.8%). Small abscesses occur in about 7.8%. They heal, however, relatively soon and without giving any persistent lesions. In newborn infants abscesses occur much more rarely (0.3%) than in older children and in adults. Nor does B.C.G. vaccination involve any other unpleasant effects. Birkhaug's needle-puncture method cannot be recommended.

The newborn become tuberculin-positive after vaccination to the same extent as older children and adults, subsequently remaining positive for several years.

Of the 22,413 B.C.G. vaccinated cases during the period 1942-7 only one developed tuberculosis—a pleuritis in a probationer nurse who was tuberculin-negative in spite of two B.C.G. vaccinations.

In other places where B.C.G. vaccination has been employed to a great extent a definite impression has been made that it gives good protection against tuberculosis, although on account of the absence of controls this cannot be regarded as proved.

In earlier investigations published conjointly with Hedvall I have shown that pulmonary tuberculosis in adolescents often develops in connexion with a recent primary infection. Several of the Scandinavian investigators have arrived at a similar view. The investigation of a tuberculosis epidemic in a school has thus been placed it beyond all doubt that B.C.G. vaccination can prevent a development of progressive pulmonary tuberculosis in the majority of cases.

B.C.G. vaccination of all newborn infants and the vaccination of non-reactors, first proposed by Heimbeck, ought for this reason to be carried out to the greatest possible extent.

EXPOSURE TO D.D.T.

BY

A. ANDERSON, M.D., D.P.H., D.I.H.

AND

M. A. KHORRAM, M.D.

(From the Anglo-Iranian Oil Co., Ltd., Iran)

Since 1943 some millions of people must have been exposed to D.D.T. in various forms and for varying periods of time, and it would appear from common experience that poisoning from D.D.T. in its insecticidal forms is most unlikely. Individual cases of poisoning have been recorded, but the effects of any solvent or vehicle used have seldom been completely ruled out. This applies especially to the common mixture of D.D.T. in kerosene.

In July, 1946, D.D.T. residual spraying on a large scale was started in Abadan, South Iran. The solvent used was commercial kerosene, and fairly frequent chemical examinations showed that a concentration of D.D.T. ranging from 3 to 4% was being obtained. Also in use was a 25% solution of D.D.T. in "black oil" (a mixture of 75% gas oil and 25% fuel oil), which meant that there were three broad groups of exposed persons—the sprayers, the "black oilers," and the mixers.

The sprayers were young men of the sweeper class who were trained to apply D.D.T. in kerosene to the walls of quarters and outhouses as a residual spray. The apparatus used was a standard "Four Oaks" knapsack spraying machine with a fine nozzle. The sprayers were organized in gangs, each gang being responsible for the spraying of a given housing area once every two months. The exposure was twofold—by the skin and by inhalation.

The "black oilers" were trained searchers for mosquito larvae. They carried a 1-litre can full of 2.5% solution of D.D.T. in gas-oil-fuel-oil mixture, and when they found mosquito larvae they sprinkled this solution on the breeding-place and reported it on returning to the office at night. The exposure was by the skin only.

The mixers prepared both solutions in a yard. The first step was to prepare a sludge of D.D.T. by crushing the powder in solvent in a 4-gallon (18-litre) tin and transferring the sludge to a 30-gallon (136-litre) drum of solvent. Difficulty in obtaining rapid solution was experienced, especially in the winter, which accounts for the fluctuation in the final concentrations obtained. The exposure in this case was by the skin only.

After nine months of this fairly continuous exposure it was felt that an opportunity presented itself of attempting to assess the occurrence of any deterioration in health. Accordingly, those who had been exposed to D.D.T., numbering 32 in all, were clinically examined and the results recorded on a standard card. A control group of 36 sanitary workers were examined by the same means. The sanitary

inside on their use under the conditions pertaining in Abadan, where the maximum shade temperature may rise to 123° F. (50.55° C.), and was maintained during the summer of 1947 at a daily average of over 110° F. (43.3° C.) for two months. The only equipment they would consent to use was overalls and goggles, and the latter but rarely. These workers therefore have spent their working days with D.D.T. in solution in contact with the skin of their hands, arms, and shoulders. They also inhaled it in fine droplets or mist as it emanated from the "Four Oaks" sprayer.

So far as this investigation goes there is no reason to believe that the continual use of D.D.T. in kerosene in a concentration of 3.1% gives rise to any toxic effects. We agree with Gordon (1946) that it is unfortunate that kerosene is the commonest, cheapest, and most readily available solvent, and would add our voice to his plea for the use of a less noxious solvent, or for the increased use of emulsions where these are practicable.

Summary

Iranian workers engaged in handling D.D.T. in oily solution were examined clinically and compared with a control group of sanitary workers, especially as regards weight and blood pressure without significant difference being observed. It would seem that intoxication is most unlikely to arise from exposure to D.D.T. in oily solution under the conditions of use described here, where the wearing of protective clothing is impossible.

We wish to thank Dr. S. D. McClean, Chief Medical Officer to the Anglo-Iranian Oil Co., Ltd., for permission to publish this article.

TRAUMATIC PSEUDO-CYST OF THE PANCREAS WITH PLEURAL EFFUSION REPORT OF TWO CASES

BY
B. J. BICKFORD, M.B., F.R.C.S.

Registrar, Liverpool Chest Surgical Centre, Broad Green
H. North, Liverpool. Late Wing Commander, R.A.F.V.R.

The general features of cysts and fluid collections in relation to the pancreas are well known. The two cases here reported were associated with a left-sided pleural effusion and appear to be unusual enough to warrant publication.

Case 1

An R.A.F. sergeant aged 20 was crushed between two motor vehicles on Nov. 28, 1945, and was admitted to an R.A.F. General Hospital on the same day. He was found to have multiple fractures of the most important of which were fractures of the left side of the pelvis and of the lower end of the right rib. There was no apparent fracture of the ribs. He was at first treated on a plaster spica, and the wrist was immobilized in a plaster cast. After reduction of the fracture of the right radius and the left leg was placed in a Thomas's splint. Four days later the patient was moved to the left lower chest and his temperature was 101° F. (38.3° C.). The pyrexia gradually subsided. It was apparent that he had a considerable pleural effusion. This was confirmed by x-ray examination. Pleural fluid

to the amount of 10 ml. was aspirated for diagnostic purposes. It contained many red cells; of the leucocytes present 52% were polymorphonuclears and the remainder lymphocytes. As the fluid continued to increase, 1,090 ml. of blood-stained fluid was aspirated on Dec. 17 and 400 ml. on Jan. 5, 1946.

His temperature subsided after the initial fever, but rose to 100° F. (37.8° C.) on Jan. 7. He had no abdominal symptoms or physical signs until Jan. 8, when a swelling was noted in the left upper abdomen. This swelling rapidly increased in size and on the 9th presented a smooth, well-demarcated semi-circular edge which reached the midline in the epigastric region and extended downwards almost as far as the umbilicus. It appeared to originate beneath the left costal margin, did not move with respiration, and was dull on percussion. A radiograph of the chest showed that a moderate-sized pleural effusion was still present, and a film of the abdomen showed a clear shadow in the left upper abdomen which displaced the stomach to the right and the intestine downwards. The left pleural cavity was aspirated, but only 20 ml. of deeply blood-stained fluid could be withdrawn.

Various possible diagnoses were entertained at this time, but the presence of a rapidly enlarging abdominal swelling could not be readily reconciled with a pleural effusion becoming gradually more deeply blood-stained. It was thought that there might be a delayed rupture of the spleen, with a haematoma in the lesser sac. The abdomen was explored through a large subcostal incision under general anaesthesia on Jan. 9. A large cystic swelling was found to be occupying the left side of the upper part of the abdominal cavity. It was about 8 in. (20 cm.) in diameter and presented between the stomach and the transverse colon, displacing the former to the right and adherent to the thick wall of the cyst. The cyst wall was anchored to the anterior parietal peritoneum and was drained by a large tube brought out through a separate stab incision. The cyst contained about 1,100 ml. of clear yellowish fluid with a slightly green tinge. The diastatic index of the fluid was 10 units, and small amounts of trypsin were present, but no lipase. The patient made an uninterrupted recovery from the operation. By connecting the drainage-tube to a bottle beside the bed excretion of the skin was entirely avoided. By the first post-operative day the fistula had become dry and remained permanently so.

During convalescence the pancreatic function was further investigated. There was normal splitting of the faecal fat, and the glucose-tolerance curve was normal. The haemoglobin progressively diminished after operation. On Jan. 16, 150 ml. of blood-stained fluid was aspirated; eight days later on March 5 the patient was feeling very well. A radiograph of the chest showed that the effusion had completely disappeared. He was discharged on March 25, and when seen again on April 8 he had no abdominal symptoms and his wound remained soundly healed.

Case 2

An airman aged 21 was crushed between a wall and a motor vehicle on Nov. 20, 1945, while serving in Germany. He was admitted to a British general hospital and underwent laparotomy on the same day. A ruptured spleen was removed and an intraperitoneal abscess of the small intestine was reduced. At first he made a good recovery from the operation, but eight days later he developed a cough with blood-streaked sputum. A left-sided pleural effusion was discovered, and 16 days later, on Dec. 14, 850 ml. of orange-coloured fluid was aspirated. He was evacuated by air on Dec. 31, and was admitted to an R.A.F. general hospital in this country.

He complained only of occasional cramp-like pain in the left lower chest and upper abdomen. On examination he was rather thin, but the only definite abnormality was a left pleural effusion, confirmed by x-ray examination. On Jan. 3, 1946, 10 ml. of the fluid was aspirated for diagnostic purposes. It contained fairly numerous leucocytes, of which 92% were lymphocytes. It was sterile on culture. He had few symptoms, but showed little clinical improvement. On Jan. 16, 57 days after the accident, he vomited once, and himself noticed a swelling in the abdomen. None had been present when he was examined few days before, but now there was a large swelling in the left

TRAUMATIC PSEUDO-CYST OF THE PANCREAS

costal region. It felt tense and was somewhat tender. It extended downwards from beneath the left costal margin almost to the umbilicus, and, to the right, 1 in. (2.5 cm.) across the midline. It was dull on percussion, with a band of resonance crossing its lower part. Coming so soon after the fracture was made, its lower part. A midline upper abdominal incision was made and a laparotomy was undertaken under general anaesthesia. A large thick-walled fluid collection was immediately found. It filled the lesser peritoneal sac, and the stomach and transverse colon were spread out over its anterior wall, to which they were intimately adherent and from which they could not be separated without causing troublesome bleeding. It did not appear to be possible to perform an anastomosis between the stomach and the jejunum, and after aspirating 1,700 ml. of slightly blood-stained fluid a drainage-tube was inserted into the cyst between the stomach and the transverse colon. The cyst wall was anchored to the abdominal wall and the tube was brought out through a separate stab incision to the left of the main incision, which was then closed. There was a considerable ooze of blood from the wound on the first post-operative day, and as this was not affected by blood transfusion and by injection of 80 mg. of vitamin K, the wound was reopened under general anaesthesia. Numerous small bleeding-points in the superficial part of the wound were secured, and thenceforward progress was satisfactory.

The fluid drained from the cyst had a diastatic index of 8 units, and contained trypsin in fairly large amount, but lipase was not present. From 200 to 300 ml. of fluid was drained daily at first and was deeply blood-stained for three weeks. The 30th post-operative day the amount of discharge had greatly diminished and the tube was removed. Ten days later the discharge, although small in quantity, had produced an area of digestion around the sinus mouth. The reaction of the fluid was alkaline, and dressing with 1% acetic acid produced rapid improvement, although it was not until the 79th post-operative day that the sinus was finally healed. The pleural effusion rapidly subsided after operation, and a radiograph of the chest on Feb. 1 (15th post-operative day) showed that the fluid had absorbed. During convalescence the pancreatic function was normal, as judged by a glucose-tolerance curve and by splitting of the faecal fat. On March 20 barium meal showed normal appearances in the stomach and duodenum, without any displacement, filling, and emptying. Normal gall-bladder concentration, filling, and emptying. He was sent to a rehabilitation unit on April 16, and when four weeks later he was feeling quite well apart from becoming rather easily fatigued.

Discussion

Much the most common type of cyst of the pancreas is the "pseudo-cyst" due to the escape of pancreatic secretion into the tissues after injury or acute pancreatitis. The frequency of or associated with chronic pancreatitis is variable. Thus trauma in cases reported in the literature is variable. Judd (1921), McWhorter (1925) of 134 cases recorded by Judd (1921), Koucky, Beck, and Todd (1941), Rabinovitch and Pines (1942), Johnson and Judd, Mattson, and Mahorner (1931), Johnson and Todd (1941), Rabinovitch and Pines (1942), 14 (9.6%) appear to have been preceded by significant trauma. On the other hand, almost a quarter of the cases in the large series collected by Koerte (1898) and by Takayasu (1898) had a history of injury.

The two cases now reported are peculiar in that each was accompanied by a large left-sided pleural effusion, an association which does not seem to have been previously noted. The cause of the effusion was the result of injury to the chest wall or lung at the time of the initial accident. In Case 1 there may have been a small haemothorax which in turn excited a reactive effusion. In Case 2 a post-traumatic consolidation of the lung may well have caused a pleural effusion. It is unfortunate that there

was no reason for giving particular attention to the chest in the early stages of the illnesses, but no sign of a fracture of the ribs could be seen in radiographs of the chest taken after the effusion had cleared. Injury to the lung may, of course, occur even in the absence of obvious fracture of the ribs. Other possible causes of effusion would appear to be pulmonary infarction, or a reaction to the diaphragm. But irritating fluid under the left dome of the lung, and it is very rare after infarction of the lung, and it seems certain that a reactive effusion would have been noted in other reported cases of pseudo-pancreatic cyst if this sequence of events was at all common. Furthermore it is not possible to reconcile the deeply blood-stained fluid noted in Case I with the irritation hypothesis.

One other feature of these two cases calls for comment. It is that increase in the size of the swelling in the abdomen took place very rapidly—indeed, in the first case causing some alarm on this account. Koucky, Beck, and Todd (1941) reported six cases in which a pancreatic pseudo-cyst ruptured spontaneously into the general peritoneal cavity. Four of these patients died. It is evident that the rapid enlargement of a swelling suspected of being a pseudo-cyst of the pancreas is an indication for early operative treatment without too much delay on account of uncertainty of diagnosis.

The usual method of treatment of a pancreatic pseudo-cyst in the past has been simple drainage, and this gives results which appear on the whole to be satisfactory. Sometimes secondary pancreatic fistula needs further treatment—e.g. by implantation into the stomach (Gutierrez, 1926) or by radiotherapy (Culler, 1920; Hamilton, 1922). Where it is practicable the most satisfactory operative procedure would seem to be primary anastomosis of the cyst to the stomach (Mahadevan, 1943) or to the jejunum (Chesterman, 1943); it may not always be technically possible on account of the situation of the cyst and the nature of its wall. Treatment by repeated aspiration is both ineffective and dangerous.

Summary

Two cases of pancreatic pseudo-cyst following closed abdomino-thoracic injury are described. Both were associated with a left-sided pleural effusion which is thought to have been due to a concomitant injury to the chest wall or lung.

The aetiology and treatment are briefly discussed. I wish to express my thanks to Group Captain J. C. Scott and Wing Commander Christopher Hardwick, who referred these cases to me. Acknowledgment is also due to the Director General of Medical Services, Royal Air Force, for permission to publish details of these cases.

They are endorsed by the Nurses' Salary Committee and accepted by the Minister of Health. The total annual value of salary and emoluments now ranges from £230 to £250 according to qualifications.

BALANCED-PULSE GALVANISM

APPLICATION OF A NEW PRINCIPLE AVOIDING
IONIZATION EFFECTS

BY

C. E. G. WICKHAM, M.B., M.R.C.S.

*Wing Commander in Charge of R.A.F. Medical Supplies
Organization*

Ordinary methods of galvanic stimulation are associated with certain limiting disadvantages, chiefly the ionization effects, burning or pain, inseparable from prolonged unidirectional stimulation. These side-effects often preclude the use of current strong enough to produce adequate contraction in some denervated muscles, and so seriously limit the usefulness of this form of therapy. A number of valve-operated stimulators are on the market, but they normally provide only unidirectional current and require a reversal mechanism whereby the polarity can be reversed for a period sufficient to neutralize ionization effects. The necessity for such current reversal leads to unwanted cathode or anode closing contractions.

This communication describes an apparatus for galvanic stimulation free from such disadvantages. It was evolved at the suggestion of Professor H. J. Seddon, of the Wingfield-Morris Orthopaedic Hospital, Oxford, and Dr. C. B. Heald, at that time Consultant in Physical Medicine to the Royal Air Force, and was developed and produced in the laboratories and workshops of the Royal Air Force Medical Supplies Organization at the hands of Mr. R. Brennan, A.M.I.E.E., and Mr. B. C. Elliott. In view of the principle employed, it has been called a "balanced-pulse generator," and continuous clinical trials in Royal Air Force rehabilitation units over the past two years amply confirm that this principle overcomes the disadvantages of ordinary galvanism.

The principle of balanced-pulse galvanism is that when a slow sinusoidal wave-form is produced wherein a stimulating pulse of relatively high amplitude and short duration is followed by a pulse of opposite polarity, subliminal in amplitude and prolonged in duration, and the relative values of these pulses can be equalized or "balanced," then no ionization effects are produced at the active electrode. Mathematically

$$It=iT \text{ or } It-iT=0$$

where I = intensity of stimulating pulse current, t = duration of stimulating pulse current, i = intensity of opposing pulse current, and T = duration of opposing pulse current. By keeping the opposing pulse subliminal in intensity it produces no contraction, and by ensuring an almost "square" form to these pulse waves true galvanism effects are obtained. It has also been found that by giving a sloping wave-front of some 60 milliseconds' duration to the stimulating pulse the pain effect of stimulation is normally less than with ordinary galvanism. Fig. 1 shows cathode-ray oscil-

FIG. 1

lograph of the current produced by the balanced-pulse generator and the current produced by comparable intermittent unidirectional stimulation pulse of the balanced-

pulse generator has the following electrical characteristics: maximum peak voltage available, 150; milliamperes peak voltage available, 25; type of current, semi-sinusoidal (with subliminal reversal); pulse frequency, 0.5 cycle/second; pulse duration, 0.3 second; polarity, constant.

The advantages of employing this "balanced-pulse" principle are that, since ionization is eliminated, stimulation is less disturbing to the patient, who can now tolerate current far stronger than would otherwise be bearable; so allow of a more effective muscle contraction being attained. Furthermore, with the absence of any ionic burning or even reaction of erythema, longer treatment can be given at each sitting and there is no tissue damage to prevent the early re-employment of the same motor point for further treatments.

The electrical circuit of the generator employs three valve stages and a full-wave valve rectifier to furnish the necessary D.C. power from the normal A.C. mains supply. The first valve stage produces a sinusoidal output at 0.5 cycle per second. This frequency is a pre-set one, which, however, can be altered if required. The second valve "squares" the character of this sinusoidal wave by means of a pre-set variable bias control and regulates the ratio between the pulse and its quiescent period. This ratio is arbitrarily fixed at 1:5. The third valve stage provides a balancing component, which is capable of variation through a pre-set potentiometer. This balancing component cater with outputs up to a predetermined limit, and for settings are required if higher outputs are used, otherwise ionization will occur. To avoid ionization effects, settings must be so prearranged that the product of "pulse amplitude" and "time," for both pulse and quiescent phase are equal—i.e., the areas covered by the wave forms on either side of the datum line must be equal.

The apparatus has proved to be very simple in operation there being only two panel controls to operate. These are an output-control knob and a meter-resistance switch whereby easily readable deflections of the centrally mounted output milliammeter may be obtained throughout the whole range of output available (see Fig. 2).

FIG. 2

Work is now proceeding to improve on the present apparatus so that, instead of a single arbitrary type of balanced pulse being produced, a selection of pulses with varying durations and at different frequencies will be available. Among other advantages this apparatus will include an improved balancing network which will be correct for all values of patient load and output-control setting. This it is felt, should provide a greatly improved replacement for the existing types of stimulators which do not utilize the balanced-pulse principle. Such an apparatus would allow accurate calibration of doses and permit currents with the characteristics found best suited to each individual case to be recorded and repeatedly applied as necessary.

Summary

A valve-operated stimulator is described whereby interrupted galvanism, free from ionization side-effects, can be given. The principle employed in the production of the current ensures freedom from ionic burning at the active electrode without the use of any current-reversal mechanism, and treatment from this source of galvanism is less painful and avoids tissue damage at the motor point.

I am indebted to the Director General of the Royal Air Force Medical Services for permission to publish this communication, and Squadron-Leaders E. F. Mason and W. J. W. Sharrard for many technical reports and much helpful advice and criticism.

Medical Memoranda

Coronary Artery Disease, Hypertension, and Hypercholesterolaemic Xanthomatosis

It is our purpose to draw attention to a well-defined clinical syndrome of related cutaneous and cardiac disease, and to illustrate the condition by reference to two cases. Substernal discomfort related to effort, or vague dyspeptic symptoms occurring in patients showing cutaneous xanthomata, should be carefully investigated.

Atheroma of the coronary arteries is undoubtedly the commonest cause of angina pectoris or cardiac infarction, and is occasionally associated with a hypercholesterolaemic cutaneous xanthomatosis. The precise relationship in man of a raised blood lipid and atheroma of the arteries is not yet clear. It may be that primary cutaneous xanthomatosis of the hypercholesterolaemic type with atheroma represents a disturbed intracellular lipid metabolism (Thannhauser, 1940). It is important to recognize this syndrome, as it may appear in relatively young persons and has a grave prognosis (*British Medical Journal*, 1939). The following two case histories are believed to be examples of this condition.

CASE 1

A housewife aged 42 had had scarlet fever at the age of 6, but had no history of any other significant illness. Her father, aged 65, was hypertensive and had experienced two hypertensive cerebral attacks. The patient had made a slow recovery from a pre-eclampsia 17 years before. Following this she began to have atulent dyspepsia and substernal discomfort.

When seen by a consultant physician four years previously she described two distinct thoracic pains: a burning sensation in the substernal region which might come on at any time, and a substernal discomfort which gripped her chest and was brought on by exertion, forcing her to rest. For these symptoms cholecystectomy was performed 12 months later. She had observed the condition to be progressive. During the three months before admission to hospital she had been forced to rest when walking up the slight incline to her house. There were no other significant symptoms.

The positive findings on examination were: xanthoma palpebrarum without other skin lesions; blood pressure of 200/130; minimal retinal arteriosclerosis; and normal cardiovascular outline and excretory pyelogram. Examination of the oesophagus with barium did not show any evidence of cardiospasm. The electrocardiogram was within normal limits. The blood non-protein nitrogen was 27-30 mg. per 100 ml., and the serum cholesterol 420-500 mg. per 100 ml. The urine was entirely normal, as was a modified urea-concentration test (McGeorge, 1945). A Smithwick lumbo-dorsal plasmapheresis was performed.

CASE 2

A housewife aged 48 had suffered from scarlet fever complicated by otitis media at the age of 3, and a hysterectomy for fibroids had been performed at the age of 46. Her mother had died at the age of 69 from coronary artery disease. An interesting family history of xanthomatosis was elicited: two female first cousins (on the paternal side), aged 48 and 50, being affected by xanthomatosis of the skin of a few years' duration. The patient did not smoke or drink.

Three and a half years before admission she began to experience pain in the chest and palpitation for the previous six to nine months the pain had become more severe. It was classically anginal in type, was brought on by slight exercise, excitement, meals, or cold weather, and was relieved by rest or glyceryl trinitrate. She had never had pain at rest or any prolonged thoracic pain. She had, in addition, of pain in the neck and jaws, right shoulder, and arm. She complained of flatulence but not nausea or vomiting. Menopausal symptoms had followed the hysterectomy.

The patient showed bright yellow xanthomata at the inner canthi of both eyes. The heart was normal in shape, size, position, and sounds; the blood pressure was 210/130; there was no albuminuria; the electrocardiogram was normal; the patient's serum cholesterol was 630 mg. per 100 ml. A lumbo-dorsal sympathectomy proved fatal. At necropsy advanced coronary and aortic atheroma was observed.

We wish to acknowledge the guidance of Prof. Henry Cohen and Dr. E. T. Baker-Bates.

Torsion of the Gall-bladder

Torsion, or volvulus, of abdominal organs accounts for a fair proportion of acute emergencies. Ovarian cysts and the sigmoid colon are the commonest sites, but few, if any, abdominal organs are immune. The gall-bladder rarely undergoes torsion. When it does, early recognition of the need for operation is vital. Recovery is the rule after operation during the first 48 hours, but a high mortality attends operation delayed beyond this period.

CASE REPORT

A man aged 67 was admitted to Redhill County Hospital, Edgware, on June 15, 1946. He complained of colicky abdominal pain of increasing severity which had started on the previous day. He had vomited once. The bowels had not been opened despite the administration of an enema. He had had no similar symptoms previously and his health had been fairly good, though he had had some indigestion.

On examination the patient was pale and appeared toxic and rather septic. The temperature was 97° F (36.1° C), pulse 100. The tongue was very dirty. The heart was enlarged. There was board-like rigidity of the whole abdominal wall, with pronounced tenderness which was maximal in the right hypochondrium. No mass was felt.

Operation.—In the evening of the day of admission the abdomen was opened by an upper right paramedian incision. The black shiny fundus of the swollen gall-bladder (see accompanying photograph) immediately presented. Further inspection revealed a complete torsion of the neck and patches of gangrene on the body of the gall-bladder. The neck was unswollen and cholecystectomy was performed with great ease. The abdomen was closed without drainage.

Photograph of black, distended gall-bladder showing site of torsion

Post-operative Course.—For the first two or three days evidence of toxæmia persisted. Dirty fluid was aspirated from the stomach through a Ryle's tube, and 1 pint (570 ml.) of plasma and 1 pint of glucose-saline were given intravenously. Subsequently the patient improved rapidly. He was allowed up on the tenth post-operative day and left hospital in good health a week later.

COMMENT

Torsion of the gall-bladder occurred atypically in a male patient. The clinical picture conformed with the usual descriptions, but tenderness and rigidity of the abdominal wall prevented the palpation of a tumour. The gall-bladder had a short attachment by its neck to the liver. There were no gall-stones.

Torsion of the gall-bladder may be diagnosable pre-operatively if a rounded mobile swelling varying in hardness is palpable in the right hypochondrium; otherwise the condition is apt to be mistaken for acute cholecystitis, perforated duodenal ulcer, or acute appendicitis. Should non-operative treatment be contemplated on the basis of one of these diagnoses, the possibility of the existence of a strangulation, or a twisted gall-bladder, *inter alia*, should be carefully considered, for in such conditions delayed operation greatly jeopardizes the life of the patient.

FRANK FORTY, M.B., B.S., F.R.C.S.
Surgeon, Redhill County Hospital, Edgware.

Reviews

ELECTROCARDIOGRAPHY

Unipolar Lead Electrocardiography. Including Standard Leads, Unipolar Extremity Leads and Multiple Unipolar Precordial Leads. By Emanuel Goldberger, B.S., M.D. (Pp. 182; 88 illustrations, 20s.) London: Henry Kimpton, 1947.

This book is a small classic. Here modern electrocardiographic interpretation is shown to rest on sound scientific criteria and to have outgrown empiricism. The author must be congratulated on presenting valuable data clearly, concisely, and methodically. No word or illustration is wasted. This is a book no cardiologist should be without. Dr. Goldberger maintains that an electrocardiogram should include precordial leads V1-6, unipolar extremity leads, and the three standard leads. Few who have bothered to use these leads will disagree. The author's augmented unipolar extremity leads are naturally preferred to Wilson's leads. He clearly explains the mathematical relationship between all the extremity leads and upholds the Einthoven triangle theory.

The left side of the interventricular septum is believed to be stimulated before any other part of the heart. This, followed by the outward spread of the excitation wave through the walls of the ventricles, is held responsible for the normal QR pattern in leads which face the left ventricular surface, for the QS pattern in leads which face the left ventricular cavity, for the RS pattern in leads which face the right ventricular surface, and for the RS pattern in leads which face the right ventricular cavity. The large Q wave in QR patterns seen in posterior V leads is attributed to the fact that such leads face the cavity as well as the surface of the left ventricle. All QRS configurations can be analysed in terms of these five basic patterns.

The author fully describes the effects of rotation in three planes. Rotation about the antero-posterior axis gives rise to the well-known vertical or horizontal positions. The QS complex seen in V1 with vertical hearts is ascribed to transmission of left ventricular cavity potentials to this lead. VF shows a QR pattern because it faces the surface of the left ventricle. Clockwise rotation about the longitudinal axis results in RS patterns from V1 to V4 or 5. Anti-clockwise rotation brings QR patterns further to the right than usual—i.e., to V3 or 4. Posterior rotation about the transverse axis, or backward tilting of the apex in vertical hearts, may cause both VR and VL to exhibit a QR pattern, reflecting potentials at the back of the heart, and lead VI may show an RS pattern because it faces the surface of the right ventricle.

With regard to maximum voltage he sets the limit at 12 mm in V1 (with horizontal hearts) and at 19 mm. in V1 (with vertical hearts). Higher voltage denotes left ventricular hypertrophy. Low voltage is accepted if the amplitude of QRS is less than 5 mm. in each of the augmented unipolar extremity leads.

The author distinguishes ventricular strain from ventricular hypertrophy and recognizes it by the occurrence of T-wave changes indicating a reversed direction of spread of the regression vector, and of certain parabolic QRS changes—that is, RS-T depression and T-wave inversion in V5 and 6 in left ventricular strain, and in V1-3 in right ventricular strain, QRS remaining normal.

The interpretation of the abnormal electrocardiogram follows the same principles but is everywhere coloured by the important consideration of the position of the heart and recognized by the characteristic changes in the extremity leads. For example, an inverted T wave in V1 and a QR pattern in V1 merely indicate a backward tilting of the apex. A QR pattern in V1 represents potentials at the

RECENT THERAPEUTICS

The 1947 Year Book of General Therapeutics. Edited by Oscar W. Bethica, Ph.M., M.D., F.A.C.P. (Pp. 455; illustrated, 21s.) Chicago: The Year Book Publishers. London: H. K. Lewis and Co. 1947.

Abstracts may be intended to indicate only the scope and contents of articles in a particular field of medical knowledge, serving merely as guides to fuller sources; but if they are made longer it should be to spare the busy general reader from having to seek the original. Editorial comment can help to restore the perspective altered by condensation. Conclusions given without the means of assessing the evidence for them may arouse curiosity, but they cannot uncritically be carried into practice. These principles have not always been followed in the abstracts that make up this book. The abstracts as well as the works from which they are drawn vary in quality, and the editor gives us little help in separating the good from the bad. Some of the most satisfactory abstracts are those in which original tables have been reproduced, and we wish more space could have been given to such original data. As it is many of the claims put forward for treatments old and new must appear dogmatic.

With these reservations this member of the "Year Book" series will help many to learn the recent progress in therapeutics for it provides in a conveniently accessible form the conclusions from some of the most important medical papers that have appeared in 1946 and 1947. The value of old remedies such as gold and salicylates is reassessed. The dangers and limitations of gold salts in rheumatoid arthritis are again stressed; BA may be a useful antidote to toxic reactions. The accounts of sulphonamides and penicillin do not take up so much space as in recent years; their uses are already well defined, but new ways of giving them are being investigated. A mixture of sulphonamides is safer than the equivalent dose of a single compound. Adequate blood levels of penicillin can be achieved with large doses by mouth, and caronamide and sodium benzoate delay excretion. For most of us streptomycin is still an untried antibiotic; we may look forward to using it in infections caused by Gram-negative bacilli and *Haemophilus influenzae*, but results in *Salmonella* and *Brucella* infections are discouraging. There are informative abstracts on BAL, thiouracil derivatives, including the promising propyl compound; the antihistamine drugs; the nitrogen mustards; and radiophosphorus. The pharmacologist provides several new preparations, including the insulin mixtures and curare. There are few results of recent vitamin research that require notice in clinical medicine. A few papers on folic acid have been included, but without warning of the risk of cord degeneration that patients with pernicious anaemia may suffer when treated with this remedy. Pyridoxin is being tried for radiation sickness. Some of the striking results of vitamin-D therapy for lupus vulgaris are summarized.

The effect of the war is still evident, for there are few contributions from the Continent of Europe; on the other hand we owe BAL and the nitrogen mustards to war research, and in the last few years there has been much good work on the treatment of tropical diseases which is now being brought together.

L. P. R. FOURMAN.

TEXTBOOK OF GYNAECOLOGY

Gynecology. With a section on Female Urology. By Lawrence R. Wharton, Ph.B., M.D. Second edition. (Pp. 1,027; 471 illustrations, 50s.) Philadelphia and London: W. B. Saunders Company, 1947.

The first edition of this book appeared in 1943 and was universally acclaimed as one of the great textbooks of gynaecology in the English language. The author has taken very great care in bringing the new edition up to date. He discusses most of the recent gynaecological work and has included many new illustrations. The paper is far better than that of the 1943 edition, and the new illustrations are of high quality. The sections on female urology are outside the province of British gynaecologists, although they may be studied with interest.

The arrangement of the book is open to criticism, for the action on the examination of the patient might more conveniently be placed before the descriptions of dysmenorrhoea and irregular haemorrhage. The book's main fault is the disproportion between the extreme detail of some parts and the superficiality of others. The author discusses carcinoma of the vulva very superficially and should have written much more on leucoplakia and kraurosis of the vulva. The chapter on ovarian tumours is inferior to the rest of the book. The literary style is harsh and often discordant. The sentences are short and to the point—rather like a mass production of Macaulay. The historical allusions are of very great interest and are well chosen, particularly the story of the work of Marion Sims on urinary fistulas and of McDowell's operations for the removal of ovarian tumours. On the other hand, the author does not mention Matthews Duncan's description of metropathia haemorrhagica, nor give priority to Percival Pott for removing both ovaries from a woman in the child-bearing period of life. Perhaps the most admirable feature of the book is the great emphasis the author places on the diagnosis of carcinoma of the cervix in its earliest stages and the very careful discussion of the aetiology of this form of carcinoma. All who teach gynaecology should study the pages after p. 493, on the treatment of carcinoma of the cervix. Throughout the book operative treatment is well described and well illustrated, in particular the Manchester-Fothergill operation, which is beautifully illustrated. The author emphasizes the interposition operation too much. The book is long, and, though not sufficiently comprehensive, should be invaluable to senior students of gynaecology.

WILFRED SHAW

OBSTETRICS FOR STUDENTS

Gynaecological Practice. By Alfred C. Beck, M.D. Fourth edition (Pp. 966; 1,068 illustrations. 38s. 6d.) Baltimore: The Williams and Wilkins Company. London: Baillière, Tindall and Cox 1947.

This book was first published in 1935 and is perhaps not so well known in Britain as other standard textbooks published in the U.S.A. It is intended for undergraduates and young practitioners, but we might expect that the former at least would be deterred by a book of nearly 1,000 pages. However, large clear print with ample spacing and profuse illustrations account for its size. The subject matter, with the possible exceptions of chapters on the physiology of the foetus and placenta and on the maternal metabolic changes during pregnancy (which are otherwise excellent), is not too detailed or advanced and makes for easy reading and learning. The illustrations, which are mainly simple line drawings, are basically the work of the author and constitute the most attractive feature of the book. Having studied these no student should find the slightest difficulty in understanding the various mechanisms of labour, pelvic anatomy, or obstetric manoeuvres.

The order in which the author discusses the subjects departs from tradition and has much to be said in its favour, although it is unfortunate that he describes pelvimetry in association with the management of labour rather than as a feature of antenatal care. The author never fails to refer to the physiological background when describing clinical conditions. The pen portraits of famous obstetricians of the past, which are interspersed throughout, serve to broaden the outlook of the reader and to arouse interest. Indeed, the book has many good points, but the chapter on analgesia and anaesthesia deserves special mention.

In general, however, the author's outlook on management and treatment is so conservative as to run the risk of being termed old-fashioned. This criticism applies especially to the sections on breech delivery and uterine action and its disorders, as well as many others, and to the attitude adopted throughout towards lower-segment caesarean section. For instance is pubiotomy really preferable to this operation in the treatment of mento-posterior position? It is unfortunate that the methods of treatment advocated tend to lag behind our knowledge of physiology and pathology, for the book has otherwise so much to commend it—above all its teaching diagrams.

BOOKS RECEIVED

[Review is not precluded by notice here of book's recent receipt]

The Training of a Doctor. By the Medical Curriculum Committee of the B.M.A. (Pp. 151. 7s. 6d.) London: Butterworths. 1948.

This book was the subject of a leading article in the *Journal* of May 29 (p. 1033).

Mental Testing of Hebridean Children in Gaelic and English By C. A. Smith, M.A., B.Ed., and D. N. Lawrie, M.A., D.Sc. (Pp. 42. 1s.) London: University of London Press. 1948.

A monograph, with statistical analysis, on the testing of 415 children.

The Question of Lay Analysis. By Sigmund Freud (Pp. 91 9s.) London: Imago Publishing Coy. 1947.

An essay on psycho-analysis by laymen, first published in 1926.

Die Beiderseitige Nierensteinkrankheit. By Dr. B. Böhm. (Pp. 169. 60 Austrian shillings.) Vienna: Wilhelm Maudrich. 1948.

A monograph on bilateral renal lithiasis, with emphasis on treatment.

Ärztliche Rheokardiographie. By W. Holzer and K. Polzer. (Pp. 141. 15 Austrian shillings.) Vienna: Wilhelm Maudrich. 1948.

The author describes his method of electrocardiography with a special circuit.

Grundriss der klinischen Diagnostik. By Hans Homrath, M.D., D.Ph. (Pp. 698. Rm. 18.) Berlin: Urban und Schwarzenberg. 1947.

A manual of clinical diagnosis in medicine.

The Practice of Group Therapy. Edited by S. R. Slavson. (Pp. 271. 21s.) London: Pushkin Press. 1947.

Articles by American psychiatrists and psychologists on different aspects of group therapy.

Gynaecological and Obstetrical Anatomy. By C. F. V. Smeut, M.D., M.R.C.S., and F. Jacoby, M.D., Ph.D. 2nd ed. (Pp. 243. 30s.) London: Edward Arnold. 1948.

Intended primarily for undergraduate and postgraduate students.

Modern Mental Treatment. By E. C. Davy, M.B., B.S., B.Sc., D.P.M. (Pp. 83. 4s. 6d.) London: Faber and Faber. 1947.

An account of mental treatment by physical methods; intended for nurses.

Problems of Hospital Administration. Edited by C. E. Prall. (Pp. 166. No price.) Chicago: Physicians' Record Coy. 1948.

A study based on personal interviews with 100 hospital administrators.

The Pathology of Nutritional Disease. By R. H. Follis, Jr., M.D. (Pp. 291. 35s.) Oxford: Blackwell. 1948.

A textbook with bibliography.

Some British Pioneers of Social Medicine. By Major Greenwood, D.Sc., F.R.C.P., F.R.S. (Pp. 118. 12s. 6d.) London: Geoffrey Cumberlege (O.U.P.). 1948.

Essays on public health in the 18th and 19th centuries.

Fear. By M. P. Leahy, M.B., B.Ch., B.A.O. (Pp. 165. 10s. 6d.) London: Research Books. 1948.

The treatment of fear by suggestion described for the intelligent layman.

Youthful Lawbreakers. Report by the Liverpool Council of Social Service. (Pp. 45. 2s. 6d.) Liverpool University Press. 1948.

A study of juvenile delinquency in Liverpool.

Bilharzial Cancer. By M. A. Affifi, M.B., Ch.B., M.R.C.S., L.R.C.P., D.M.R.E. (Pp. 111. 16s.) London: H. K. Lewis. 1948.

A monograph on radiological diagnosis and treatment.

Operative Gynecology. By H. S. Crossen, M.D., and R. J. Crossen, M.D. 6th ed. (Pp. 999. 75s.) London: Henry Kimpton. 1945.

A profusely illustrated textbook, with operative details.

Hypnotherapy. By M. Brenman, Ph.D., and M. M. Gill, M.D. (Pp. 276. 18s.) London: Pushkin Press. 1948.

A survey of the literature.

REMUNERATION OF SPECIALISTS

The Report of the Spens Committee on the Remuneration of Consultants and Specialists was published a week ago, and a slightly abridged version is printed elsewhere in this issue. The Committee took evidence from the Evidence Committee on the Remuneration of Consultants and the Specialists set up jointly by the Royal Colleges and the British Medical Association, and also separately from the 23 medical organizations represented on that Committee. Prof. A. Bradford Hill prepared for the Evidence Committee the necessary statistical information, and this was put at the disposal of the Spens Committee. Some of the results of Prof. Hill's inquiry are given in tables which are also reproduced in this *Journal*. The Spens Committee in its recommendations had to consider what were the normal financial expectations of specialist practice in the past, and what effect its proposals might have upon the recruitment of specialists and consultants (specialists for short) in the future. The information before the Committee related to incomes earned in the year 1938-9, and it is important to remember that the recommendations made are in terms of the 1939 value of money. The Report stresses that adjustments should take into account the changed value of money since then, and the increased incomes in the medical and other professions; but the comment might be made that the changes in income have in part at least been determined by the increased cost of living. The Report makes recommendations for the future of the potential specialist, and also for the existing specialist.

The Report makes recommendations for the remuneration of the potential specialist and the established specialist, and for the setting up of a national committee to distribute graded awards to those of outstanding ability. Its first set of recommendations will go far to remove the gravest handicap to the young man able and wanting to practise as a specialist. It is not so many years ago that one of the London teaching hospitals paid its sole medical registrar (non-resident) the salary of £250 a year. The Spens Committee considers that when a registrar post is reached the practitioner should not have to rely upon private means or upon such outside work as coaching to make it possible for him to live. It considers that remuneration for junior hospital posts in the past had little relation to the progressively responsible position of these posts, to the standard of living required of the practitioner, and to the need for freedom from financial worry during this part of his career. The Committee, therefore, proposes that the potential specialist should between the end of his first house job and his appointment to the staff be paid a salary which would be equivalent to a training grant and also corresponds to the status of a trainee in his skill and responsibility. It divides the first stage into three grades: (1) Posts obtained after registration, and (2) Posts obtained after completion of the first year of living. The Committee also holds that the salary should apply working in both teaching and non-teaching hospitals being related to the intention that in the future there should be a more uniform level of remuneration throughout the country, and a better distribution of specialists. But the Committee seems to have had some thoughts when in another part of the Report it suggests that those who combine clinical work with teaching should have a higher total remuneration. It is recommended for all specialists the retiring age should be 65. Coming to its second major problem the Committee recommends that a specialist appointed to a hospital staff should be paid £1,500 a year, provided he has reached the age of 32, which it takes to be the usual age of appointment. At the other end of the scale it considers that specialists of the highest eminence should be able to earn £5,000 a year—this, it should be remembered, is in terms of 1939 value of money. Between these ranges the average specialist on a hospital staff should by the age of 40 be paid £2,500 a year (1939 value). These recommendations, of course, apply to those working whole-time in the hospital service, and to the salaries recommended it is proposed to add expenses incurred in professional work, including matters as attending national and international professional meetings. To provide incentive and to reward outstanding work the Committee recommends that there should be an addition to the basic specialist salary of £2,500 for a fixed percentage of the total number of specialists. In the first instance an additional award of £2,500 a year to 4% of the

alists; in the second, an addition of £1,500 for 10%; in the third, an addition of £500 for 20%. All being whole-time in the public hospital service will be eligible for these awards; and those working part-time, for appropriate portions. The Committee then goes on to the controversial of its recommendations in its suggestion that these awards shall be made by a national committee, professional members of which are to be nominated by the Royal Colleges and the Scottish Royal Corporations, among its members a representative of the University and of the Medical Research Council. Consultants and specialists should scrutinize this recommendation with

We may imagine the embarrassment of such a committee if some of its members were still in Grade 3, or even Grade 2. The procedure contemplated will be open to abuse, even though such abuse might not be evident to the committee in session. We believe it is inadvisable that a committee composed largely of specialists working in this financial control over all specialists working in the National Health Service. Will the committee at its first meeting debar its own members from these awards? Surely there will be in the new hospital service positions of unusual responsibility demanding men of the highest calibre, and to such posts it would appear to be logical to attach the highest salaries recommended. The Report, for example, to the especially long training of the neurosurgeon and the thoracic surgeon. To take this as an example, would not the post of neurosurgeon to one or more regions call for a higher remuneration than the basic specialist salary of £2,500 a year? It is to be hoped that consultants and specialists generally will voice their opinions on this procedure, which is the one outstandingly satisfactory proposal in a Report which is likely to commend itself to those who will work as consultants and specialists in the new Service.

LIQUID PARAFFIN RISKS

Paraffinum liquidum (B.P.) is a refined product which must conform to certain specifications and which is generally believed to be free from substances harmful in themselves. Experimental and clinical observations support this belief. It is not to say that regular consumption of liquid paraffin in substantial quantities and over a long period, for whatever reason, is always desirable; recent evidence, indeed, would indicate that this is not so.

During the late war liquid paraffin (B.P.) for therapeutic use became increasingly scarce, and chemists were often unable to meet doctors' prescriptions. The scarcity was due partly to diminished production, but increased consumption was undoubtedly the main cause, not for medicinal purposes, however, but because liquid paraffin and indeed other mineral oils were being used as substitutes for fat in cooking. The practice began quite early in the war, and it seemed to increase *pari passu* with the decline of fat supplies. Food and drug authorities tried to check the commercial use of liquid paraffin for this purpose, but they could do little to stop its employment in domestic cookery. Indeed, some voluntary organizations were actively fostering the practice. The Ministries of Food and Health took what steps they could to discourage it,

but in the absence of clear evidence showing that harmful paraffin little effective action was possible.

In 1945, at the instigation of the Ministry of Health, workers at the University of Birmingham began to investigate the effects of liquid paraffin, heated and unheated, on nutrition. Liquid paraffin (B.P.) was used, and the heated samples were kept at certain temperatures for varying times, with and without aeration. The heating was of the same intensity and duration as that used for cooking cakes and other foodstuffs. The samples thus obtained contained variable amounts of oxidation and breakdown products. The biological investigations showed that the daily consumption by rats of raw or heated liquid paraffin (B.P.), in doses up to 2 ml. per 200 g. body weight daily, had no demonstrable effect on the growth or reproduction of rats over two generations. Some interference with vitamin A and carotene absorption was observed, especially when supplements of these substances were added to the diet. A large series of experiments showed that raw paraffin had no deleterious effect upon the activity of intestinal enzymes. Heated paraffin reduced lipolytic activity slightly, but this was not thought to have any biological significance. Workers in the U.S.A. have also demonstrated that the absorption of carotene and other fat-soluble vitamins is reduced by liquid paraffin.¹ In a series of experiments carried out in Chicago on human beings it was found that the faecal excretion of vitamin A and carotene was increased when mineral oil was added to the diet. At the same time the level of vitamin A in the plasma fell, though not to an abnormally low level.²

The effect of heating mineral oils and paraffin had previously been studied at the Royal Aircraft Establishment at Farnborough, and it had been noticed that high temperatures produced oxidation products with fluorescent spectra similar to those of carcinogenic substances. Investigations were later undertaken at the University of Oxford to ascertain whether these oxidation products possessed carcinogenic properties. Samples of heated paraffins which had been studied from the standpoint of nutrition at Birmingham were investigated at Oxford for their carcinogenic activity in a series of long-term biological experiments. No evidence of such activity was found, nor were cancerous changes in the alimentary tract observed during the long-term feeding experiments. It is, however, well known that cancer is extremely difficult to produce in the alimentary tract, even if potent carcinogens are given by mouth. It would be unwise, therefore, on the basis of these findings alone to exclude the protracted consumption of heated paraffin as a possible cause of cancer; the onset of this disease is too insidious to warrant such an optimistic attitude.

Frazer and his colleagues in Birmingham have shown that liquid paraffin is absorbed when administered in finely dispersed emulsions of particle size less than 0.5 μ . It is not known whether the oil is as finely dispersed in flour products, such as cakes and pastry, baked with liquid paraffin. Whatever the degree of dispersion, however, the continued ingestion over long periods of substantial

¹ Report of Council on Foods and Nutrition, *J. Amer. med. Ass.*, 1943, 123, 967.
² Mahle, A. E., and Patton, H. M., *Gastroenterology*, 1947, 9, 44.
³ Alvarez, W. C., *ibid.*, 1947, 9, 315.

amounts of paraffin may result in the deposition of paraffin in the intestinal wall, the mesenteric lymph glands, and in the liver.² Deposits in these tissues were found at necropsies on persons dying from various diseases who had consumed liquid paraffin for years. Paraffin is not metabolized, and continued ingestion presumably would lead to accumulations of the oil. Though we do not know the precise fate of such deposits, we cannot be indifferent to their presence in the body.

The above objections apply with greater force to the use of ordinary mineral oils as substitutes for fat. This practice has been increasing even more rapidly than that of using liquid paraffin. Most unrefined mineral oils contain small amounts of undesirable substances, even though the absence of colour, odour, and taste might suggest the contrary. In some of these oils cancer-producing substances have been identified.

On the evidence available, therefore, the use even of refined liquid paraffin (B.P.) in the preparation and cooking of food is to be condemned. It has a definite therapeutic value, and its use should be restricted accordingly. In view of the possible risks of continued consumption, liquid paraffin should be taken only on medical advice, and the doctor prescribing it would do well to bear the risks in mind. The internal use of other (unrefined) mineral oils in any shape or form must always be condemned.

PREVENTION OF INFIRMITY

In 1946 the Nuffield Foundation published the report of a Survey Committee set up, under the chairmanship of Mr. B. Strehorn Rowntree, to inquire into the living conditions of old people. This report aroused considerable interest for it was the first time that a serious attempt had been made to assess the problems of old age, and has served as a useful help and guide for much public activity and recent legislation. This has now been followed up by a detailed medical survey, conducted by Dr. J. H. Sheldon,¹ in one of the areas, Wolverhampton, already covered by the social survey of the Rowntree Committee. Dr. Sheldon's report will prove helpful to those who wish to carry out further researches into the problems of old age, and will also serve as a model for similar inquiries. As Dr. Sheldon points out, his survey covers only Wolverhampton, and it is impossible to be certain that the same conditions apply to other areas, both urban and rural, of the country. With so much legislation of social and medical importance coming into force it is important that other authorities, taking Dr. Sheldon's report as their guide, should arrange this summer for surveys to be carried out in their areas in order to assess the size and nature of their own problem.

The Rowntree Committee drew attention to the fact that in 1939, when it was necessary to continue to employ in the professions of both sexes for many years beyond what was considered the normal time for retiring, it was found that a small number of elderly people were capable of doing work as well as and as satisfactory as their juniors. Dr. Sheldon states that this is not until the age of 70, or even 75, when people begin to become affected by conditions which make it impossible for them to continue in their work.

tions that might be regarded as the result of age; and that time it is the common diseases of adult life that affect the elderly. These two observations have a bearing upon the whole question of compulsory retirement at the age of 60 or 65, and lend weight to the argument put forward by Dr. Trevor Howell that not only are old people able to work until quite an advanced age but that work up to their capacity leads to an improvement in both their physical and mental health. Further, in an era of full employment when the work of all who are able and willing is needed for their country's good, it is satisfactory to discover that an encouragement to work is not only a suitable policy for the times but is in no way detrimental to the welfare of the aged.

The report draws attention to two fields where there is need and scope for voluntary or official effort. Sheldon emphasizes the strength of family or filial ties, as instances, by the large number of people who devote a considerable amount of their time to the care of aged relatives. Though these are not necessarily bedridden—indeed the number of these discovered in the survey was surprisingly small—they require constant attendance, and the strain on both the younger members of the family, usually daughters, and on the old people themselves is considerable and prolonged. The provision of attractive homes, with no stigma about the name, where aged relatives could be accommodated for a short period, say, of one month each year, would enable the younger relative to take a much-needed holiday before resuming a task which they have no wish to give up. The provision of more home nursing or domestic help would not solve the problem, as even with this the relative would not be able to get away because the old person could not be left in the house alone. Some provision for nursing will be needed at homes established for old people, because though few are bedridden many require special attention. One such home has recently been opened by the London branch of the British Red Cross Society at Greenwich and is proving of great value, and one or two similar homes exist in other parts of the country. There is need for many more. Homes should be small and not stereotyped, so that the old people will not feel that they are being banished from their surroundings even for a short time. This type of hostel might well be managed and maintained by voluntary organizations, which probably have more flexibility and imagination in their undertakings than the best intentioned local authorities.

The second problem of old age calling for voluntary or official effort is that of loneliness. This is a particularly onerous feature of the lives of old people who have lost a spouse, and yet who either cannot or do not wish to abandon their own house and have to depend upon occasional, or even regular, visits to or from relatives. There is a great opportunity here for the establishment of Old People's Clubs which the members can visit each day to meet their contemporaries and old friends, or to make new ones. Regular visits from people outside the circle of family and friends are also appreciated. It has been the experience of both of the Nuffield surveyors, of relief officers, and of the officials of the National Insurance Scheme that their visits are welcomed and eagerly awaited.

The great importance of Sheldon's report is in the medical implications. He draws attention to various conditions of which but little is known, but which cause much distress in the old. The tendency to fall or to trip and difficulty in walking in the dark both point to some labyrinthine or inner ear disturbance; while an unexplained dyspnoea is one of the commonest reasons for inability to leave the house. The capacity of the aged to eat well when they have no teeth, either real or artificial, and yet to suffer no more from indigestion than their more fortunate contemporaries, is an important observation that needs further investigation. The number of the aged who appeared to be under-nourished was small. This is at variance with the observation made by other writers that a number of old people are admitted to hospitals suffering, very largely, from under-feeding. It is possible that the reason for this discrepancy is that conditions in other towns are different from those in Wolverhampton, where the old people who usually live a solitary life, alone in a house or room, are few. Sheldon discovered that a large proportion of seemingly solitary people were, in fact, visited daily by relatives or friends who assisted with cooking and with shopping. More can be done to prevent some of the minor disabilities which do so much to curtail the activities of old people. Sheldon found that a large number of old people suffered from crippling deformities of the feet—corns and bunions—which could well have been prevented by intelligent shoe-making and chiropody.

The continued activity and happiness of the old depends upon their retaining a place in the general community. It is important, therefore, that whether they live in hostels or in special houses on new housing estates they should remain in the middle of their families and friends. Old people enjoy living in their own homes, and in this they are helped by the presence and proximity of many small shops. The encouragement of the multiple store, situated near great shopping centres, may make the continued independence of the aged more difficult.

REGENERATION AND CANCER

There have always been those, particularly among biologists, who have themselves engaged in cancer research, who have maintained that the study of normal growth was a necessary preliminary to the understanding of pathological growth. The argument appears to be strengthened by an investigation reported by S. Meryl Rose and Hope M. Wallingford at a recent meeting of the National Academy of Sciences of the United States.¹ The approach of these two workers was based on the de-specialization recognized as accompanying the first stage in limb regeneration, for example in the salamander. Re-specialization follows under a directive mechanism which is not yet fully understood but which may be assumed to be chemical in its nature. The question, therefore, to which an answer was sought was whether cancer cells subject to the drastic stimulus of amputation and regeneration could be induced to make a fresh start and re-specialize as normal healthy cells. Transplants of frog tumour were used, since the nuclei of frog cells are smaller than those of salamander cells, so that the origin of regenerated cells could be cytologically identified. Sufficient time was allowed after transplantation into the forelimb of

a salamander for the tumour to begin growth and to invade the neighbouring tissues. Amputation was then carried out through the cancer. Normal regeneration followed, and patches of frog muscle, cartilage, and connective tissue could be "seen interspersed with the corresponding salamander tissues." On the other hand, the residual portion of the tumour, which had been left on the proximal side of the amputation, remained as before.

A fuller account of these experiments will be awaited with interest. In particular, there is an assumption that the normal frog tissues formed during regeneration originated from cancer cells; in other words, that no normal frog cells accompanied the transplant. It would be expected, however, that these, if present, should have been identified in the residual tumour, while the extent and variety of normal frog tissue in the regenerated limb would seem also to exclude such an explanation. If confirmed, these results should provide a useful stimulus to the further study of the mechanisms of regeneration, which, in relation to the volume of cancer research, may be judged to have received too little attention.

CHANCES OF SURVIVAL IN PULMONARY TUBERCULOSIS

Attempts to estimate the average duration of pulmonary tuberculosis in the general population have been infrequent and our knowledge is derived from a few relatively small and local inquiries in recent times. This paucity of data is due to the difficulties of keeping in touch with all the patients notified in any one area. Considerable labour and time are needed if a large wastage through loss of contact is to be avoided, and even when determined efforts are made not to lose sight of patients the number disappearing amounts, in some inquiries, to almost 10% of the total.

Fraser² has recorded the history of 1,257 sputum-positive cases of pulmonary tuberculosis—843 notified in the City of Aberdeen and 414 in Aberdeenshire—in the ten years, Jan. 1934–Dec. 1943. For all ages and both sexes combined the probability of surviving five years after diagnosis was 0.45. This value is smaller than that generally found from a follow-up of patients who have had sanatorium treatment, but of course such patients form a selected group. On the other hand, a poorer chance of survival has been recorded in investigations similar to that carried out by Fraser. Thompson³ found that the probability of surviving five years was 0.25 in County Durham; Bentley⁴ estimated that for L.C.C. patients the figure was 0.34; Tattersall⁵ found a probability of 0.32 for Reading; Vailow,⁶ in Bradford, gave the figure as 0.41 for males and 0.65 for females; Stocks⁷ calculated that 50% of patients in England and Wales survived five years after diagnosis. It would appear from these comparisons that Aberdeen has enjoyed relatively favourable mortality experience. An examination of the Aberdeen figures by age and sex showed that in the youngest age group (10–19) the males had a considerable advantage over the females, but in the other age groups the males had only a slightly better chance of surviving than the females during the first years after diagnosis.

Fraser also examined the influence of collapse therapy on prognosis. Three hundred and ninety-nine, or 31.7% of the patients, had received this form of treatment. In this group the chance of surviving five years after the diagnosis had been made was 0.68, a value 50% greater than that

obtained when all the patients were included. In 921 patients the disease was classified as stage 3, and of these 319, or 34.6%, were treated by collapse therapy. The probability of surviving five years in the case of patients in this stage of the disease was 0.36 for those not receiving collapse treatment and 0.66 for those who did receive it. Patients with less extensive disease—classified as stages 1 and 2—had a probability of surviving five years of 0.72. This value is only slightly higher than that for patients in stage 3 who had received collapse therapy. Eighty of the patients in stages 1 and 2, about one-quarter of the total, had undergone some form of collapse therapy. Since the patients with disease in stage 3 who received collapse treatment had substantially the same chances of survival as the patients with less extensive disease Fraser concludes that collapse therapy prolongs life. Bentley came to the same conclusion, having found in two comparable groups that the probability of surviving five years for patients who had undergone artificial pneumothorax was 0.49 for males and 0.45 for females, while for patients treated by conservative methods the probabilities were 0.28 and 0.32 respectively.

The value of the investigation in Aberdeen would have been enhanced if information had been given concerning the number of persons who were lost sight of during the period

CATHETERIZATION OF THE HEART

Catheterization of the right auricle has been an accepted technique for over fifteen years, and much valuable information has been obtained, especially by Cournand in the United States and by Prof. J. McMichael at the Hamman-Richmond Hospital in this country. Recently Dexter¹ and his colleagues in Boston have made more accurate diagnosis possible in cases of congenital heart disease by further improving the technique. In this condition exact diagnosis of the defect was not so important a few years ago, but now that surgical treatment is sometimes feasible it has become imperative to obtain as much pre-operative information as possible.

The Boston team, whose work is of outstanding practical importance, has shown that much can be learned from a study of the oxygen content of the blood in various parts of the heart and great vessels, supplemented by pressure measurements. The technique used and possible errors are described by Sosman.² By careful manipulation the catheter can be passed from the right auricle into the right ventricle, thence into the main pulmonary artery and its left or right branches, and even into the smaller terminal divisions. As many as ten blood samples may be taken from one patient.

Dexter describes the results of the procedure in cases of auricular septal defect, ventricular septal defect, Fallot's tetralogy, and patent ductus arteriosus. In auricular septal defect, for example, the oxygen content of the blood in the right auricle is higher than that in the superior vena cava, indicating a predominating left to right shunt. If the oxygen content of the blood in the right ventricle is higher than that in the right auricle a ventricular septal defect is suggested, and a much increased pressure in the right ventricle is strong corroboration. A patent ductus arteriosus is associated with a higher oxygen content in the descending aorta than in the right ventricle. It is also possible to estimate the amount of blood passing through these

In some cases the abnormal course of the catheter indicates the presence of an anatomical anomaly. Thus it may pass directly from the right to the left auricle and into a pulmonary vein, from which blood with an oxygen saturation of 98% may be obtained. Or it may pass into the right ventricle through a septal defect into the aorta. The position of the catheter is verified by screening and by radiographs. The papers describing the work of the Boston team are illustrated with most convincing pictures of the various positions of the catheter, and these are correlated with the results of the physiological tests.

These tests, though predominantly physiological, are in part complementary to the more anatomical information given by angiocardiology. Chávez³ and his colleagues have described a method of direct angiocardiology in which a catheter, size 12–14, is introduced into the heart through the external jugular vein. This procedure seems to have certain great advantages over the Robb-Steinberg technique, in which the contrast medium is rapidly injected into an arm vein. The use of the short, wide catheter, moreover, gets over difficulties which cannot be avoided with the usual long, thin cardiac catheter if introduced through an antecubital vein for direct intracardiac angiocardiology. There seem to be no special drawbacks or dangers in the method providing a suitable vein is available. Again, the pictures accompanying the article by Chávez are models of clarity and rich in information.

The rapidity with which these diagnostic procedures have been evolved, so closely following on the development of the surgery of congenital heart disease, is remarkable. Investigation by the Dexter and Chávez methods will provide information which can be obtained in no other way.

DIETHYLACETAMIDE IN SHOCK

During the war the German workers Hecht and Weese¹ working at the I.G. Farben laboratories in Elberfeld introduced as a blood substitute a substance formed by the polymerization of vinyl pyrrolidone. They showed that it could take the place of blood plasma, and it was soon employed clinically.² Various plasma substitutes which appeared to be of a similar kind were studied in N. America, such as gelatin and pectin solutions, and isinglass. All these were believed to act by their osmotic properties alone.

In 1946 Daniel Bovet and his colleagues,³ working at the Institut Pasteur, examined polyvinyl pyrrolidone for its value in traumatic shock. They chose to study this condition because they had previously investigated shock caused by histamine and its prevention by antihistaminic substances such as neoantergan. They produced shock in rats by the method of Noble and Collip, in which rats are placed in a drum which revolves in a vertical plane (the axis of the drum being horizontal), so that the rats fall to the bottom as the drum revolves. When rats are placed in the drum, their fate depends on the number of revolutions. An increasing percentage of rats die as the number of revolutions increases—100% die after 800 revolutions. Bovet found that if the rats received an injection of polyvinyl pyrrolidone beforehand, given either subcutaneously or intraperitoneally in a dosage of 0.5 g. per kg. of body weight, then every rat survived 800 rev-

⁴ *ibid.*, 1946, 224, 496.

⁵ *Lancet*, 1943, 245, 147.

tions. The mortality was reduced even if the injection as made as long as 72 hours before the trauma. They tested the protective power of this substance against the toxin of *Cl. oedematiens* and diphtheria toxin and found that whereas 32 control animals all died in two days after receiving *oedematiens* toxin (0.16 ml. per kg.), of 2 animals protected with polyvinyl pyrrolidone (0.35 g. per kg.), 15 survived for 7-8 days.

The most interesting aspect of this investigation, however, came from Bovet's idea that the protective value of polyvinyl pyrrolidone might not lie in its physical properties but rather in its chemical composition. If the substance is split up, molecules of N-N-diethylacetamide are obtained, and strange to relate this very simple compound as found to give some protection. When 0.5 g. per kg. as given by intraperitoneal injection one hour before the rats were placed in the drum, 15 out of 40 animals survived, compared with only 1 out of the 40 controls. The injected animals which died lived for a mean time of 11 hours, while the controls lived for only 3.5 hours. Other related substances were tested—some were active, some were not. Thus N-N-diethylpropionamide is effective but not N-methylacetamide.

It is obvious that this brilliant work opens up a new field of investigation, the discovery of simple chemical substances which counteract the effects of trauma, and, presumably also of toxins, provides a new and more rational conception of the pathological changes which are occurring. Perhaps the machine is not being run on the whole; perhaps, as Green suggests, there is a deficiency of deoxynucleoside triphosphate, which is a precursor of insulin, with an effective dose of insulin in the treatment of diabetes.

THE SPREAD OF Q FEVER

Q fever, or to give it its full name, *Q* (query) fever, was first described by Derrick¹ in 1937, the causal agent being subsequently shown to be a rickettsia (Burnet and Freeman²). Almost at the same time the disease was found to be occurring in Mexico in the U.S.A. Spontaneous infections were most common among those who are concerned with cattle, alive or dead. Thus stockmen and those working in slaughter-houses were most commonly affected. It was discovered that the causal agent, *Rickettsia burnetii*, was carried by various cattle ticks—in Australia by *Haemaphysalis humerosa*, and in the United States by *Dermacentor variator*, *D. occidentalis*, and *Amblyomma americanum*. In Australia the common bandicoot was reported to act as a carrier.

During the latter part of 1944 and in the following years there were outbreaks among American troops in Italy, and, and British troops in Greece and Italy. At first taken to be atypical pneumonia, *Burnet's* complement-fixation tests these outbreaks were then shown to have been due to Q fever. One such outbreak has been recorded in this *Journal* by Cassidy and Dudgeon.³ At the other end of the Mediterranean in Morocco, Blanc *et al.*⁴ have isolated the rickettsia of Q fever from ticks—*Hyalomma marginatum*, *H. excavatum* var. *h. excavatum*, and *H. excavatum* var. *h. excavatum*—and ticks on camels, or in the burrows of the *H. excavatum* rodent, the merion, *Meriones shawi*, and the prevalence of Q fever have been isolated from the spores of apparently healthy merions. In addition goats and camels in the same area carry infected ticks, and camels infected with *R. burnetii* goats, sheep, camels, and cattle are known from a febrile illness

during which rickettsiae circulate in the blood. From the New World there have been further reports of the disease from Texas (Topping, Sheppard, and Irons⁵), and from Central America, where Panama is an endemic zone. A further extension of the range of Q fever has now been reported by Gsell,⁶ who has described four small familial outbreaks in Switzerland. In the epidemics affecting troops in Italy and Greece as well as in these Swiss outbreaks the role of ticks appears uncertain.

In 1940 Findlay⁷ showed that infection could be transmitted intranasally to mice, with the production of characteristic lung lesions. It is probable that the nasal mucosa or the conjunctival sac was the point of entry in the numerous laboratory infections which have since occurred. In the National Institute of Health in the U.S.A. for instance, an outbreak began among laboratory workers in February, 1946, and by the end of May, 1947, there had been 47 cases (Spickard *et al.*⁸).

The incubation period of Q fever is 10-12 days. There are at first vague prodromal symptoms, headache, malaise, and general aching, lasting for 2-3 days, then passing to two distinct phases. These are characterized by severe headache, so characteristic of rickettsial and many virus infections, and a more definite fever of the rash. Fever lasts on an average of 10 days, but may sometimes last for 20 days, and is usually accompanied by high fever, occasionally reaching 104° F. (40° C.). Rigors and sweats are common, and there is a generalized erythema, the rash is more marked at the joints, and there is a sense of tenderness. No definite lymphadenitis, pain, or swelling of the lymphatic system is observed, and a normal fundus of the eyes there is no evidence of conjunctivitis or exanthema. On occasions there is a purpura of the skin. No significant or characteristic changes are found in the blood picture. A small amount of protein is occasionally seen. It is obvious that the signs and symptoms are such as might be present in many other rickettsial infections.

During the acute stage *Rickettsia burnetii* is present in the blood and sputum, and by inoculation into mice or guinea-pigs the rickettsiae can be isolated. They are present in the spleen of experimental animals in considerable numbers. During convalescence the best method of diagnosis is by complement fixation, complement-fixing antibodies being present 10 to 15 days after the onset of illness.

Neither penicillin, sulphonamides, nor the administration of immune serum has any marked action in shortening the disease. Paracetamol (PABA) acid therapy has not been tested, but there is no evidence from the experiments of Huebner *et al.*⁹ that streptomycin has a curative effect, not only when *R. burnetii* is injected into the developing chick embryo, but in guinea-pigs given large intraperitoneal injections of the organisms. When 30 mg. doses of the drug were injected subcutaneously three to six times a day, there was very prompt disappearance of symptoms. Treatment was continued for 12 to 16 days.

In view of its wide distribution in the Old and New Worlds it is not improbable that Q fever may be seen in this country. Sera from a few suspected cases have already been tested, but so far with negative results.

REPORT OF THE INTERDEPARTMENTAL COMMITTEE ON THE REMUNERATION OF CONSULTANTS AND SPECIALISTS

We print below the *Interdepartmental Committee's Report* to the Minister of Health and the Secretary of State for Scotland on the remuneration of consultants and specialists. The members of the Committee were: Sir Will Spens (Chairman), Mr. C. R. Dale, Sir Horace P. Hamilton, Mr. Thomas Lister, Miss Elizabeth Looker, Prof. D. Murray Lyon, Lord Moran, Mr. Leslie E. Peppiatt, Sir Harry Platt, Dr. S. Cochrane Shanks, and Mr. J. R. H. Turton.

We have completed the task for which we were appointed in May, 1947, and have now the honour to submit our report. Our terms of reference were as follows:

"To consider, after obtaining whatever information and evidence we thought fit, what ought to be the range of total professional remuneration of registered medical practitioners engaged in the different branches of consultant or specialist practice in any publicly organized hospital and specialist service; to consider this with due regard to what have been the financial expectations of consultant and specialist practice in the past, to the financial expectations in other branches of medical practice, to the necessary postgraduate training and qualifications required and to the desirability of maintaining the proper social and economic status of specialist practice and its power to attract a suitable type of recruit, having regard to other forms of medical practice; and to make recommendations."

1. *Evidence*.—It was brought to our notice that a special committee called the Evidence Committee on the Remuneration of Consultants and Specialists had been set up by the Royal Colleges and the British Medical Association jointly, with the purpose of preparing evidence on behalf of consultants and specialists generally, and we decided to consider the written and oral evidence which this Committee was prepared to submit. The Evidence Committee consulted 23 medical organizations, including the Royal Colleges and many specialist associations, in the course of its task so as to ensure that the evidence tendered, in so far as it involved expressions of opinion and judgements regarding professional matters, was in accordance with the majority views of specialists and consultants in every branch of medicine. We anticipated that these various organizations might wish to submit separate evidence in substantiation of any points which concerned them individually and which were not in their opinion adequately covered by the statements prepared on their behalf by the Evidence Committee. We accordingly invited written evidence both from those organizations which were directly represented on the Evidence Committee and also from a large number of associations representative of particular branches of specialist practice whether or not these had already been approached by the Evidence Committee. We also issued a general invitation by means of a press notice to anyone disposed to furnish us with any relevant information. [A list of the organizations and individuals from whom written statements have been received, and of the witnesses examined orally, is contained in Appendix I to the Report.]

The ready response we received to our invitation both in the form of written evidence and of offers to tender oral evidence was a great help in our investigation, and we should like to take this opportunity of expressing our indebtedness and cordial thanks to all those who assisted us in this way. In view of the large measure of agreement found in the evidence received from all sections of the profession and the exhaustive character of the information furnished by the Evidence Committee, it was not necessary to request additional oral evidence from the Evidence Committee and the Royal College of Physicians. We completed our task after holding sixteen

sources in judging what effect our recommendations were likely to have upon the recruitment of medical practitioners to the consultant ranks. The necessary statistical information was obtained for us by the Evidence Committee, which, under the guidance of Prof. A. Bradford Hill, conducted an inquiry in the form of a questionnaire to consultants and specialists. A tabular statement prepared by Prof. Bradford Hill containing some of the results of this inquiry forms an Appendix to the Report (Appendix II). We have also had regard to salary scales already in force for salaried members of the medical profession in organized medical services.

2. *1939 Values*.—At an early stage in our deliberations, it appeared to us that social and economic conditions were not yet sufficiently stable to justify the basing of our recommendations on evidence relating to remuneration in the post-war period, and the Evidence Committee was accordingly asked to obtain information of incomes earned in the year 1938-9. With this evidence before us, and realizing that we were not qualified as a Committee to form an opinion on what adjustments of immediately pre-war incomes was necessary to produce corresponding incomes to-day, we decided that the best course for us to pursue was to frame our recommendations in terms of the 1939 value of money. This conclusion has not prevented us from taking into account post-war conditions in so far as they affect the development of Medicine, particularly in regard to developments in the newer specialties and to modifications in the organization of hospital services. We leave to others the problem of the necessary adjustments to present-day values of money, but we desire to emphasize as strongly as possible that such adjustments should have direct regard not only to estimates of the change in the value of money but to the increases which have in fact taken place since 1939 in incomes both in the medical and in other professions. In our judgment it is only if corresponding changes are made in the incomes of consultants and specialists that the recruitment and status of the various branches of specialist practice will be maintained.

3. *Interpretation of Remit: Training Period*.—We were at first disposed to interpret the terms "consultant" and "specialist" in our remit as referring to those medical practitioners who after completion of a series of hospital appointments and attainment of a higher qualification are appointed to membership of the staff of a hospital. After consideration of the evidence submitted to us, however, we concluded that the remuneration appropriate to specialists of staff status was to such an extent dependent upon remuneration and conditions of service during the period of specialist training which must precede appointment to the staff that it was advisable for us to give a clear indication of what in our view would constitute adequate remuneration during this training period. We therefore ultimately decided to interpret the term "specialist" in our remit so as to include the whole group of practitioners who after registration and completion of junior house appointments are appointed to hospital posts in training for a special branch of Medicine.

4. *Past Conditions: Career Picture*.—It may be convenient to include a description of the career of a specialist from the time when he is placed on the *Medical Register*. Until now medical students have normally qualified at the age of 23 or 24 after some five or six years of undergraduate study. Immediately after qualification the practitioner may hold one or more house appointments, and this part of the postgraduate training, which normally occupies a period of one year, is an essential step for those who aspire to consultant status. During this period, or during the tenure shortly afterwards of other junior hospital posts for which he becomes eligible, the intending specialist undertakes intensive academic study with a view to securing a higher qualification in medicine or surgery and also with the aim of obtaining, at approximately four years from registration, appointment to the most senior training posts, for which a higher qualification is normally a requisite. These posts are differently named in different hospitals but are more commonly known as registrar, senior registrar, first assistant, or chief assistant. A practitioner holding one of these posts has no direct charge of patients but is responsible to his medical or surgical chief for the care of patients during the latter's absence. As he gains experience he is given more and more responsibility, so that, for instance, a surgeon in the latter part of

JUNE 12, 1948

JUNE 12, 1948

gistrarship undertakes major operations, and such supervision exists at this stage is really in the nature of assessment of potentialities as a specialist. On completion of his tenure of this post the practitioner is ready for appointment to the staff of a hospital, when he will be recognized as having full specialist status.

Life was particularly impressed by the drastic selection to the early part of their career are subjected through which they are

We were particularly impressed by the drastic selection to which specialists in the early part of their career are subjected both for appointment to the posts through which they are required to pass and for the conferment of academic awards, and distinctions which may considerably affect their career. After graduation there is keen competition for suitable house appointments, many of those who qualify being eliminated at this stage; there is further competition for appointment to each of the training posts subsequently held and finally, from the comparatively small number of registrars, etc., selection is made for appointment to a hospital staff. The distinctions for which intending specialists compete include scholarships attached on entry to medical schools, awards and medals awarded on entry to medical schools, during undergraduate training, postgraduate scholarships and finally the higher qualification normally competed for prior to registrarship and obtained by approximately one-sixth of the profession. In most hospitals the initial staff appointment is that of assistant surgeon, etc. When the term of the appointment expires, the assistant surgeon is usually im-

attached to a hospital, and the training, postgraduate scholarship, and the appointment normally completed for prior to registration. In most hospitals the initial staff appointment is that of assistant physician, assistant surgeon, etc. When the term "assistant" is used it does not necessarily imply that the holder of such an appointment is subordinate to the physician or surgeon. He may have few hospital beds in his charge or none, but he assumes complete responsibility for the patients admitted to his care.

[illegible]

It was strongly felt that the evidence that the remuneration attached to the junior hospital posts held immediately after completion of house appointments had borne little relation to the progressively increasing responsibilities of these posts to the standard of living required of the practitioner, and to the need for freedom from financial worry during this extremely important part of his career. We were told that many potential specialists are diverted into general practice at an age when marriage is contemplated and the emoluments attached to junior posts are not sufficient to meet new responsibilities. If difficulties are progressively accentuated throughout the training period, and when the registrar posts are reached, the practitioner is normally compelled to rely upon his own resources or to undertake much outside work, or to endeavour to enable him to meet his financial commitments. We were informed that hospital registrars before the war received up to £400 or less, even in non-resident posts.

In the past no substantial income has been derived from a staff appointment in a voluntary hospital, and from a successful private practice but normal remuneration from possession of such an appointment. We were however informed that a fully qualified practitioner has on several years before.

Moreover, on obtaining an appointment, whatever the specialist has had to forego his previous partnerships, and undertakes the responsibilities involved in the efficient running of a private practice. At this stage his earnings from private practice have seldom covered his overhead expenses and he has often been dependent to a considerable extent on private means to work.

6. *Future Conditions.*—In assessing the appropriate remuneration for the budding specialists of the future we have had regard to the view of the profession, endorsed by the Goodenough Committee and the General Medical Council, that the holding of pre-registration house appointments should be compulsory. We have also had regard to the long period of training required in some of the more specialized branches of Medicine. We were informed that a minimum period of five years of specialist status involving a minimum period of five years of training after medical qualification, or eleven years of professional training in all, have been proposed for most of the surgeons, consultants and specialists including general practitioners, obstetricians and gynaecologists, cardiologists, dermatologists, neurologists, paediatricians, psychiatrists and radiologists. In considering what the remuneration should be for these specialists we assumed that there will be a substantial increase in the number of specialists in the future.

In considering what we have assumed that a person's tenure status should be we have assumed that all persons in the armed forces are of tenure comparable to that of a person in the civil service. We have assumed that the conditions of service of the staffs of voluntary hospitals are comparable to those of the staffs of public service hospitals. We have assumed that a person in a public service hospital is of tenure comparable to a person in a public service hospital. We have assumed that a person in a public service hospital is of tenure comparable to a person in a public service hospital.

[illegible]

We are of opinion that the present system of remuneration is not adequate to attract and retain the best medical talent. The present system is based on a fixed fee for attendance, which is insufficient to cover the cost of the services rendered. We recommend that the remuneration be based on a percentage of the total cost of the services rendered. This would be a more equitable system, and would also be more in line with the practice of other professions. We also recommend that the remuneration be based on the complexity of the case, and on the time and effort expended. This would be a more equitable system, and would also be more in line with the practice of other professions. We also recommend that the remuneration be based on the results of the treatment. This would be a more equitable system, and would also be more in line with the practice of other professions.

8 *Equality of Status between Hospitals.*—We have had regard also to the view of the profession and the intention underlying the National Health Service Act that in the hospital system of the future there should be a more uniform level of hospital efficiency throughout the country, a better distribution of specialists, and permeation throughout the hospital service of each region of the influence of the university centre. These objects can be achieved only by increasing the mobility of specialists throughout the service and facilitating the interchange of staffs between teaching and non-teaching hospitals. The hospital system of the future is being organized in such a

may that there will be in each region both teaching hospitals and area hospital centres. The many small independent hospitals, both general and special, which are at present scattered throughout the country will be linked in these area hospital centres. From the viewpoint of the patients it is desirable that modern advances in Medicine should be made available in areas outside the radius of the present teaching centres. In these circumstances it is obviously important that the status of the area hospital centre should be in no way inferior to that of the teaching hospital, and that both should be able to attract specialists of the highest calibre. We are therefore of opinion that the same range of remuneration for clinical work should apply to specialists in both teaching and non-teaching hospitals:

PROPOSALS

9. *Remuneration of Potential Specialists.*—We now turned to our first major problem: that of determining the proper remuneration for potential specialists after completing one year's house appointments and before obtaining a post on the staff of a hospital.

In framing proposals on this subject we have had prominently in mind the evidence about past conditions during the training period to which we call attention in Section 5 above. We are of opinion that in a public service intending specialists who do not possess private means should not be called upon to pass through a stage of comparative penury and hardship. Nor should they be tempted to spend too much time in supplementing their income from other sources, such as coaching, when they could be more suitably occupied in their professional studies. Having regard to the career picture which we have drawn from the evidence, we consider that the medical practitioner between the completion of his first house appointment and appointment to the staff, should be paid a salary which is not merely in the nature of a training grant but which reflects both the growth in his skill and the increasing responsibility of his work.

We have referred already to the lengthening of the period of training which is likely to be involved in the future organization of medical studies, and, in particular, we considered sympathetically the position of practitioners undergoing specialist training in those branches of Medicine which already demand an exceptionally long period of training, such as neuro-surgery and thoracic surgery. Moreover, whilst realizing the inadvisability of making it easier for individuals to prolong indefinitely their tenure of posts below those of full staff status, we think it necessary to safeguard the position of the fully trained specialist who is compelled to wait a limited time for a vacant staff appointment. At the same time we wish to emphasize that in our opinion all possible steps should be taken by encouraging the interchange of specialists between hospitals to minimize and equalize this unavoidable waiting period.

We are of the opinion that it is necessary for the purpose of our remit to reduce proposed salaries during the training period to the various posts which are successively held prior to appointment to the staff. We realize that the nomenclature of these posts differs widely in various parts of the country, and we have thought it best to define them by reference to the number of years for the duration of which they are normally held. These appointments may thus be divided into three well-defined grades:

1. Category I - persons obtained normally not less than one year of service in the post of a senior official officer, etc.);
2. Category II - persons obtained normally not less than two years of service in the post of a senior registrar, etc.);
3. Category III - persons obtained normally not less than four years after the date of their appointment for three years at the ages of 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100, 101, 102, 103, 104, 105, 106, 107, 108, 109, 110, 111, 112, 113, 114, 115, 116, 117, 118, 119, 120, 121, 122, 123, 124, 125, 126, 127, 128, 129, 130, 131, 132, 133, 134, 135, 136, 137, 138, 139, 140, 141, 142, 143, 144, 145, 146, 147, 148, 149, 150, 151, 152, 153, 154, 155, 156, 157, 158, 159, 160, 161, 162, 163, 164, 165, 166, 167, 168, 169, 170, 171, 172, 173, 174, 175, 176, 177, 178, 179, 180, 181, 182, 183, 184, 185, 186, 187, 188, 189, 190, 191, 192, 193, 194, 195, 196, 197, 198, 199, 200, 201, 202, 203, 204, 205, 206, 207, 208, 209, 210, 211, 212, 213, 214, 215, 216, 217, 218, 219, 220, 221, 222, 223, 224, 225, 226, 227, 228, 229, 230, 231, 232, 233, 234, 235, 236, 237, 238, 239, 240, 241, 242, 243, 244, 245, 246, 247, 248, 249, 250, 251, 252, 253, 254, 255, 256, 257, 258, 259, 260, 261, 262, 263, 264, 265, 266, 267, 268, 269, 270, 271, 272, 273, 274, 275, 276, 277, 278, 279, 280, 281, 282, 283, 284, 285, 286, 287, 288, 289, 290, 291, 292, 293, 294, 295, 296, 297, 298, 299, 300, 301, 302, 303, 304, 305, 306, 307, 308, 309, 310, 311, 312, 313, 314, 315, 316, 317, 318, 319, 320, 321, 322, 323, 324, 325, 326, 327, 328, 329, 330, 331, 332, 333, 334, 335, 336, 337, 338, 339, 340, 341, 342, 343, 344, 345, 346, 347, 348, 349, 350, 351, 352, 353, 354, 355, 356, 357, 358, 359, 360, 361, 362, 363, 364, 365, 366, 367, 368, 369, 370, 371, 372, 373, 374, 375, 376, 377, 378, 379, 380, 381, 382, 383, 384, 385, 386, 387, 388, 389, 390, 391, 392, 393, 394, 395, 396, 397, 398, 399, 400, 401, 402, 403, 404, 405, 406, 407, 408, 409, 410, 411, 412, 413, 414, 415, 416, 417, 418, 419, 420, 421, 422, 423, 424, 425, 426, 427, 428, 429, 430, 431, 432, 433, 434, 435, 436, 437, 438, 439, 440, 441, 442, 443, 444, 445, 446, 447, 448, 449, 450, 451, 452, 453, 454, 455, 456, 457, 458, 459, 460, 461, 462, 463, 464, 465, 466, 467, 468, 469, 470, 471, 472, 473, 474, 475, 476, 477, 478, 479, 480, 481, 482, 483, 484, 485, 486, 487, 488, 489, 490, 491, 492, 493, 494, 495, 496, 497, 498, 499, 500, 501, 502, 503, 504, 505, 506, 507, 508, 509, 510, 511, 512, 513, 514, 515, 516, 517, 518, 519, 520, 521, 522, 523, 524, 525, 526, 527, 528, 529, 530, 531, 532, 533, 534, 535, 536, 537, 538, 539, 540, 541, 542, 543, 544, 545, 546, 547, 548, 549, 550, 551, 552, 553, 554, 555, 556, 557, 558, 559, 560, 561, 562, 563, 564, 565, 566, 567, 568, 569, 570, 571, 572, 573, 574, 575, 576, 577, 578, 579, 580, 581, 582, 583, 584, 585, 586, 587, 588, 589, 590, 591, 592, 593, 594, 595, 596, 597, 598, 599, 600, 601, 602, 603, 604, 605, 606, 607, 608, 609, 610, 611, 612, 613, 614, 615, 616, 617, 618, 619, 620, 621, 622, 623, 624, 625, 626, 627, 628, 629, 630, 631, 632, 633, 634, 635, 636, 637, 638, 639, 640, 641, 642, 643, 644, 645, 646, 647, 648, 649, 650, 651, 652, 653, 654, 655, 656, 657, 658, 659, 660, 661, 662, 663, 664, 665, 666, 667, 668, 669, 670, 671, 672, 673, 674, 675, 676, 677, 678, 679, 680, 681, 682, 683, 684, 685, 686, 687, 688, 689, 690, 691, 692, 693, 694, 695, 696, 697, 698, 699, 700, 701, 702, 703, 704, 705, 706, 707, 708, 709, 710, 711, 712, 713, 714, 715, 716, 717, 718, 719, 720, 721, 722, 723, 724, 725, 726, 727, 728, 729, 730, 731, 732, 733, 734, 735, 736, 737, 738, 739, 740, 741, 742, 743, 744, 745, 746, 747, 748, 749, 750, 751, 752, 753, 754, 755, 756, 757, 758, 759, 760, 761, 762, 763, 764, 765, 766, 767, 768, 769, 770, 771, 772, 773, 774, 775, 776, 777, 778, 779, 780, 781, 782, 783, 784, 785, 786, 787, 788, 789, 790, 791, 792, 793, 794, 795, 796, 797, 798, 799, 800, 801, 802, 803, 804, 805, 806, 807, 808, 809, 810, 811, 812, 813, 814, 815, 816, 817, 818, 819, 820, 821, 822, 823, 824, 825, 826, 827, 828, 829, 830, 831, 832, 833, 834, 835, 836, 837, 838, 839,

rising by two annual increments of £100 to £1,100. Where tenure of a post in Grade I continues beyond three years the salary should rise by a further increment to £1,200 in the fourth year and remain at this figure in any further years. In recommending these salaries we have in mind non-residential posts; where residential emoluments are received, an appropriate sum would require to be deducted from the salary.

10. *Range and Differentiation for Full Consultants.*—The second major problem to which we addressed ourselves was to determine the total range of remuneration for consultants of full staff status, and to secure within this range sufficient differentiation of incomes to provide the necessary incentives, consistent with the two principles referred to above—equality of status between the various branches of specialist practice, and equality of status between teaching and non-teaching hospitals.

11. *The Lower Limit of the Range.*—In discussing this should be the lower limit of the range and remuneration for staff specialists, we took into account the effect which this figure will inevitably have upon recruitment. The adequacy of the remuneration for the first few years will more than any other factor determine the attitude of the practitioner who is considering whether or not to embark upon the arduous path of specialization. As regards starting salary we agreed to recommend that on appointment to the hospital staff a specialist should receive £1,500 per annum, provided he has attained the age of 32, which we think will be a normal age.

In the exceptional case where a specialist is appointed to a hospital staff at the age of 30 or below we recommend that the starting salary should be £1,250, rising by annual increments of £125. It would follow that if a man were appointed at the age of 31 he would receive £1,375 on appointment, and £1,500 at 32. It may often happen that a specialist will not attain a 2nd appointment for some years after the age of 32. In that case we recommend that the hospital authorities should have freedom to vary the initial salary of £1,500 by allowing up to four special increments of £125 each in respect of age, special experience, and qualifications.

12. *The Maximum Figure of Remuneration.*—The statistical tables prepared by Prof. Bradford Hill show that it has been possible for a small proportion of practitioners in the past to obtain incomes of a very high order. Bearing in mind that the salaries we have recommended above would remove the hardships at present experienced during the period of training; that in a public service the specialist ought not at any stage of his career to require to supplement his earnings by private means; that his remuneration will be maintained at a consistent level until the age of retirement is reached; and that throughout his career the specialist will enjoy financial security in marked contrast with the uncertainties of private practice, we conclude that some reduction was justifiable not only in the ceiling figure of the incomes attainable in the past, but also in the proportion of consultants attaining to the highest levels of remuneration. On the other hand, we would emphasize that if the best possible recruits are to be attracted to specialist practice there must remain for a significant minority the opportunity to earn incomes comparable with the highest which can be earned in other professions. There is a further point to which we attach great importance. We are convinced that the remuneration offered to specialists of exceptional ability must be sufficient not only to attract the most able specialists of the country to the public service but to maintain the position of British Medicine in a competitive market which includes the Dominions and the United States of America.

After consideration of these factors we concluded that specialists of the highest eminence should be able, in public service, to aspire to a remuneration of the order of £5,000 for clinical work.

13. *Differentiation within the Range.*—We turn to the question of what should be the spread of incomes within the range of £1,500 to £5,000, and of how such a spread could be realized. We are directly concerned only with what remuneration specialists ought to receive, not with the method of their payment. On the other hand, the problems involved in determining the former cannot be wholly separated from the latter. We are satisfied that there is a far greater diversity of ability and effort among specialists than admits of remuneration by a simple scale applicable to all. If the recruitment and status of specialist practice are to be maintained specialists must be

to feel that more than ordinary ability and effort receive an adequate reward. Moreover, a reward which would be appropriate when these exist would be extravagant when they do not. In consequence we are clear that any satisfactory system of remuneration must involve differentiation dependent on professional distinction.

Acceptance of this principle without qualification would imply that age or length of service should not be a factor which determines the remuneration of a specialist. On consideration, however, we were agreed that after his appointment to the staff of a hospital, the specialist, although his training is complete and he undertakes sole personal responsibility for the patients under his charge, continues for a number of years to gain an increasing variety and width of practical clinical experience which progressively enhances the value of his work. It seems to us, therefore, that, whilst age or length of service should not at any time during his tenure of a staff appointment be the sole factor determining remuneration, there should be, during the earlier years, in addition to some means of recognizing and rewarding exceptional individual merit, a uniform scale of annual increases in remuneration applicable to all specialists alike.

We therefore recommend that the initial salary paid to the specialist on his appointment to the staff should be augmented by an additional £125 after each year of service until a maximum basic salary of £2,500 has been reached. We consider that beyond this point, which if staff status is achieved at the age of 32 would be at the age of 40, an automatic incremental basic scale of remuneration would be inappropriate and remuneration should cease to depend in any way at all upon the length of service of the specialist.

It remained for us to consider in what way a satisfactory spread of incomes could be obtained in the higher age range, and what should be the method of differentiation between specialists to achieve this spread of incomes and to ensure that in the lower age range outstanding ability should be rewarded by remuneration in excess of the basic incremental scale we have already envisaged. Although as we have said we are not directly concerned with methods of payment we are clear that if the profession is to be satisfied and recruitment maintained it is essential that a method of differentiation involving the selection of individuals for exceptional reward in respect of outstanding professional ability must be found and the confidence of the profession. We have thought it right, therefore, to indicate the kind of mechanism for achieving differentiation which appears to us to be required.

We recommend that the selection of specialists whose outstanding distinction merits exceptional reward should be in the hands of a predominantly medical body and that this body should be as detached as possible from individual hospitals and particular localities. It would be all the advisable to select and specialise members to undertake this task and we are satisfied that the provision of such machinery for the purpose would be in the public interest consisting in the main of eminent members of the profession from their own knowledge or other means and be able to reach an authoritative opinion on the comparative merits of candidates. We recommend that the constitution of this committee should be discussed with the Royal College and the Scottish Royal College and that the professional members should be nominated by these Colleges and Committees. We suggest that the committee should also include a representative of the Universities and a representative of the Medical Research Council.

In our opinion this committee could be empowered to recognize special contributions to Medicine in the field of research or otherwise even in auxiliary or non-clinical professional work (other than administrative) by the nomination of selected individuals of distinction in these fields. The first and highest distinction would be conferred with an annual award of £1,500 per annum and the second an award of £800 per annum. Additionally, specialists who are engaged whole-time in the practice of medicine should be eligible for these distinctions and for the monetary awards attaching to them. Specialists who are engaged part-time in that service should not be eligible for these distinctions and for the appropriate part of the corresponding monetary awards.

We consider that in order to preserve a proper distribution of incomes throughout the entire range of remuneration the number of distinction awards conferred should be a fixed percentage of the total number of consultants eligible and we recommend that 4 of all consultants eligible should be selected for conferment of the first distinction and 2 for conferment of the second distinction and 2 for conferment of the third distinction. This would have the effect of approximately equalizing all specialists' incomes on the basis of a salary of £2,500.

It appears to us that this method of selecting specialists would not only maintain a proper proportion of the higher incomes but would have the advantage of encouraging the incentives to stimulate effort and encourage the outstanding opportunities of higher remuneration to specialists in whatever branch of Medicine they may be engaged in. These awards might be regarded as a means of encouraging specialists to maintain equality of standards and to encourage a proper distribution of specialists throughout the country. In our mind we would emphasize that the object in mind was not to enable specialists to earn more than would in our view be merited by their services but to distinguish on the basis of a specified number of appointments, the specialist who has made a greater advance towards a higher teaching hospital service and the specialist who has made a greater advance towards a higher general practice service. The usual claims regard should be paid to the department providing such awards over the country as a whole. The branches of specialists' practice. In our mind the percentages we have had in mind are not intended to be the main basis of making possible a fixed salary scale.

14. *Part-time service*—We did not regard it as our duty to reference to make recommendations in respect of the remuneration of specialists engaged in part-time appointments. We have, however, given consideration to the general question whether the scale of remuneration for part-time specialists should be based on a proportion of the full-time scale. We have already said that we are not directly concerned with methods of payment and we are clear that if the profession is to be satisfied and recruitment maintained it is essential that a method of differentiation involving the selection of individuals for exceptional reward in respect of outstanding professional ability must be found and the confidence of the profession. We have thought it right, therefore, to indicate the kind of mechanism for achieving differentiation which appears to us to be required.

We recommend that the selection of specialists whose outstanding distinction merits exceptional reward should be in the hands of a predominantly medical body and that this body should be as detached as possible from individual hospitals and particular localities. It would be all the advisable to select and specialise members to undertake this task and we are satisfied that the provision of such machinery for the purpose would be in the public interest consisting in the main of eminent members of the profession from their own knowledge or other means and be able to reach an authoritative opinion on the comparative merits of candidates. We recommend that the constitution of this committee should be discussed with the Royal College and the Scottish Royal College and that the professional members should be nominated by these Colleges and Committees. We suggest that the committee should also include a representative of the Universities and a representative of the Medical Research Council.

In our opinion this committee could be empowered to recognize special contributions to Medicine in the field of research or otherwise even in auxiliary or non-clinical professional work (other than administrative) by the nomination of selected individuals of distinction in these fields. We have thought it right, therefore, to indicate the kind of mechanism for achieving differentiation which appears to us to be required.

REMUNERATION OF CONSULTANTS AND SPECIALISTS

BRITISH
MEDICAL JOURNAL

the basic remuneration of whole-time specialists of like status, plus one-quarter of $\frac{1}{11}$ or one-quarter of $\frac{11-x}{11}$ of that remuneration, whichever be less.*

We envisage also that special circumstances might arise where a rate of remuneration for part-time appointments higher than that recommended above should be applied, on a personal and in some cases temporary basis, to individual specialists. For example, acceptance of a part-time contract might depend upon uncertain prospects of building up or maintaining a private practice in a particular locality. We recommend that hospital authorities should have freedom to offer at least temporarily a higher rate of remuneration for part-time appointments where such special circumstances exist.

16. *Expenses, Superannuation, and Holidays.*—There are three further points to which we wish to refer in order to avoid any possibility of misunderstanding. First, throughout our proceedings we have assumed that specialists engaged either whole-time or part-time in a publicly organized service will be paid any sums which represent expenses necessarily and reasonably incurred in the course of their work, and that these sums will be in addition to the salaries recommended. The Evidence Committee has brought to our notice a number of items of expense which must be met if the specialist is to perform his duties efficiently. These include car expenses; expenses of travel apart from the use of a car; the cost of renewal of instruments and other equipment; the cost of books and journals; professional societies; printing, papers, and subscriptions to professional societies; expenses of stationery, postage, and telephone costs; expenses of attendance at national and international professional meetings; and the expenses of visiting hospitals and clinics at home and abroad, and entertaining visiting colleagues.

The expenses might be refunded after they have been incurred, or alternatively an appropriate allowance for expenses might be attached to the various posts held by specialists and consultants. If the latter course were adopted it would have to be realized that certain expenses would arise which had not been foreseen when the allowance was fixed—e.g., attendance at an international conference, and additional provision would have to be made in such cases.

It is presumed that the Inland Revenue authorities would be prepared to consider favourably as legitimate allowances for income tax purposes any items of expense which had been approved by a public hospital authority.

Secondly, in the above discussions and in the recommendations which we have made, we have assumed that, as in private practice in the past, specialists will have themselves to provide by insurance against death and old age; in so far as this ceases to be the case adjustment would be necessary.

Thirdly, in our discussions and the recommendations we have made we have assumed that in a publicly organized service the specialist would be entitled to certain definite holidays, and would not be financially liable for providing a deputy. We would add that, in our view, apart from normal holidays, extended leave will in the interests of the service be necessary on occasion for study or research.

SUMMARY

17. *Recommendations and Conclusions.*—Our recommendations regarding the remuneration of consultants and specialists in a publicly organized hospital and specialist service are, therefore, as follows:

(a) Medical practitioners in training for the special branches of medicine should receive (a) a fixed salary of £600 per annum for the first year after registration and are normally held for one year only (e.g., senior house officer, registrar, etc.). (b) A salary of £700 rising by £100 to £800 per annum during their training and are normally held for two years (e.g., assistant, junior registrar, etc.). (c) A salary of £1,100 rising by £100 to £1,200 in the fourth year, which are normally obtained after registration and are normally held for three years (e.g., first assistant, chief assistant, senior registrar, etc.). If such a post is held for more than three years the salary should rise by one further increment of £100 to £1,200 in the fourth year, and remain at that figure in any further years. Note.—These recommendations relate to non-resident posts.

(2) (a) A specialist appointed to the staff of a hospital at the age of 32 or below should receive a starting salary of £1,250 per annum. (b) A specialist appointed at the age of 31 should receive a starting salary of £1,375 per annum. (c) In the case of specialists appointed after the age of 32 hospital authorities should have freedom to vary the starting salary of £1,500 by allowing up to four special increments of £125 each in respect of age, special experience and qualifications.

(3) The initial salary of a specialist on the staff of a hospital should be augmented by an additional £125 after each year of service until a salary of £2,500 has been reached.

(4) A national committee should be set up with the task of selecting individual specialists whose outstanding distinction merits a higher reward than that which the above recommendations would provide. The constitution of this committee, which should be predominantly professional, should be discussed with the Royal Colleges and the Scottish Royal Corporations. The professional members should be nominated by these Colleges and Corporations.

(5) This committee should confer distinction awards, in three grades, on selected specialists, in recognition of special contributions to Medicine (other than administrative). (a) Distinction in the first and highest grade should carry with it an award of £2,500 per annum by way of addition to the salary recommended above; distinction in the second grade an award of £1,500 per annum; and distinction in the third grade an award of £500 per annum. All specialists engaged part-time in the service should be eligible for these distinction awards. A specialist engaged should be awarded the appropriate proportion of the corresponding monetary award.

(b) Four per cent. of all specialists eligible should be awarded the first distinction; 10% should be awarded the second distinction; and 20% should be awarded the third distinction. Note.—This would have the effect that approximately one-third of all specialists would receive remuneration in excess of £2,500.

(6) Specialists who undertake domiciliary visits should receive additional remuneration for this work.

(7) (a) Where x represents the number of half-days per week which a part-time specialist is required to work, his basic remuneration should be $\frac{x}{11}$ of the basic remuneration of whole-time specialists of like status, plus one-quarter of $\frac{1}{11}$ or one-quarter of $\frac{11-x}{11}$ of that remuneration, whichever be less.

(b) Hospital authorities should have freedom in special circumstances to offer, at least temporarily, a higher rate of remuneration for part-time appointments than that recommended above.

Note.—We have assumed (i) that a specialist in whole-time service undertakes a working week of 11 half-days; (ii) that a specialist engaged part-time in the service is required to serve a specified number of half-days per week.

(8) All specialists engaged either whole-time or part-time in the service should be paid, in addition to the remuneration recommended above, any sums which represent expenses necessarily and reasonably incurred in the course of their work.

(9) All specialists engaged in the service should be entitled to definite holidays, and to extended leave when necessary for study or research, without being financially liable for providing a deputy.

(10) It is not for us to make recommendations as to the amounts which should be paid for teaching, but we place on record our belief that in order to secure the right men it will be necessary for clinical specialists engaged in teaching, whether undergraduate or postgraduate, to receive increased remuneration.

In conclusion we wish to record our appreciation of the work of our Joint Secretaries, Mr T. B. Williamson of the Ministry of Health, and Dr. D. P. Stevenson of the British Medical Association.

Drygrange Hotel, Melrose, has been bought by the Council for the Provision of Rest-Breaks Houses for Nurses and Midwives and opened as a rest-breaks house for members of the nursing and midwifery professions. Purchase of the hotel is the first major expenditure in Scotland from the £1,000,000 South Africa Gift to Britain Fund. Drygrange Hotel is the second house of its kind to be opened in Britain. The other is Barton House Hotel, Barton-on-Sea, Hampshire, which was opened in April, 1947. These hotels also provide facilities for nurses recuperating from illness who need no nursing care, and both are open to Scottish and English nurses and midwives. Rest-breaks houses for nurses and midwives were started during the war to meet the needs of nurses and midwives suffering from "overstrain." They are run as hotels, with no restrictions, and are administered by the Council for the Provision of Rest-breaks Houses for Nurses and Midwives.

Correspondence

The Training of a Doctor

SIR.—The British Medical Association and Prof. Cohen's Committee are to be congratulated on *The Training of a Doctor*—a valuable preliminary, in a stage of chaos, to medical educational reform. In your leading article (May 29, p. 1053) you refer specifically to the recommendation that general medicine should be taught as "a basic clinical subject" and lend your support to the appeal for a renaissance of the general physician. As one who has advocated these things for many years and has urged a number of young men to make general medicine their field of practice instead of devoting their lives to an organ, a system, a diagnostic technology, or a particular therapy, I am naturally in full sympathy with the relevant sections both of the book and your leader. If anything I would have gone even further in urging that psychiatry and social medicine with medical statistics were not to be regarded as separate and additional subjects calculated to embarrass the curriculum or to create a desire for more diplomas. In fact, they should contribute to the basic structure of general medicine, unlike the technical specialisms they are a part of its bricks and mortar. The general physician who lacks good psychological training or insight, who is not constantly alive to the part played by social influences in the aetiology of disease and in recovery from it, who is uninterested in the distribution, mortality, and morbidity of common diseases, and who cannot appreciate the uses of numerical data or criticize their faulty employment, is not fully equipped for his task. Human pathology is compounded, surely, of individual and social pathology—the latter a hitherto neglected science in the teaching of the schools and one having an importance to-day not less than that of morbid anatomy and physiology. Surrounded by appropriate texts in the ward and out-patient department the general physician can come to play a large part in the teaching of medicine not only in its individual but also in its social aspects. His teaching will often require the collaboration of the almoner as medical social worker. His students should learn how to take a systematic social history. His instruction should be related in various ways and run concurrently with a modernized course replacing the more orthodox public health lectures of the past in social medicine and hygiene and the applications of vital statistics; it should also have reference to current socio-medical research in which general physicians themselves are now beginning to play a prominent part. These subjects have, in fact, a greater relevance to medical practice and philosophy than many of the specialist subjects and technical and laboratory skills which occupy so much of the present clinical period and which should, strictly, be the concern of postgraduate education.

In order among other things, to give the student further insight into the common disorders and diseases (which he rarely sees in hospital), into the methods and problems of family practice under good conditions, and into the personal health service of the mother and child, I have further suggested (*Journal* May 22, p. 1003) the establishment as soon as possible of practitioner-staffed health centres in close functional relationship with all teaching hospitals. The general physician, at the hospital level, should once more make it his purpose to develop the fundamental disciplines of medical science and practice, to occupy his students' minds with the principles of aetiological understanding and with diagnostic, prognostic, and therapeutic method. The general practitioner—given proper selection, training, opportunity, and associations—could provide a brief first introduction to the applications of these principles in situations far different from those of the ward with its highly selected methods and material. These forms of instruction should become the essential preliminary and leave to all the other clinical subjects and should equally inspire the early training of the family doctor and the specialist. As soon as possible it will be necessary for textbooks and examinations, both in the clinical subjects and in public health, to encourage and reflect these teaching reforms.

While bedside pathology, physiology, and pharmacology—Lewis's "clinical science"—have fully established their academic

CORRESPONDENCE

claims and uses, a sound and critical clinical and socio-medical discipline need not, in fact, be any less scientific; it should, furthermore, ensure a more judicial and humanistic approach to professional problems.—I am, etc.,

JOHN A. RYLE.

SIR.—The report of the Medical Curriculum Committee of the B.M.A. entitled *The Training of a Doctor* will surely be a disappointing document to all who are interested in the training of the doctor in midwifery. As my name is included in the list of those obstetricians (four in number) whose "valuable help" is acknowledged in Appendix A, I feel that I must publicly state my disagreement with some of its main recommendations and make it clear that the course of training advised by me as necessary in the memorandum submitted at the Committee's request has not been accepted. This is of course not surprising, as the Curriculum Committee did not include even one obstetrician or gynaecologist, though it did include four surgeons, four physicians, one ophthalmic surgeon, one ear-nose-and-throat surgeon, a paediatrician, and a professor of forensic medicine. In my opinion, and I speak as one who practised midwifery for 12 years in general practice and has been an undergraduate teacher of midwifery in medical schools for more than 20 years, the course in midwifery recommended, namely two months of clinical work including the time spent in deliveries, is quite inadequate to give the student the "thorough basic training in general principles" that the Committee considers necessary to "enable the practitioner to fulfil the requirements of the Medical Acts without taking a special postgraduate diploma" (p. 87 of the Report).

Has the Committee never heard of or seen the Interim and Final Reports of the Departmental Committee on Maternal Mortality and Morbidity of the Ministry of Health (1930 and 1932), the former of which contains a section on "Medical Education in Obstetrics"? If they have, they make no reference to it and do not include it in the "Select Bibliography" in Appendix B. Perhaps they preferred to ignore it because it recommended six months' clinical training in obstetrics and gynaecology, during not less than two of which the student should reside in the maternity hospital or in special quarters adjacent thereto, and that at least two-thirds of this time, i.e., four months, should be allotted to midwifery. The sad part of it all is that the recommendations of the Departmental Committee have had a great influence on the provision for training in these subjects and have been adopted by most of the leading schools and examining bodies. Now we apparently go back to the conditions of 20 years ago, losing all the ground for which enlightened teachers of obstetrics have fought during the last half-century. Better for midwifery if the B.M.A. report had never been published. I am, etc.,

F. J. BROWNE.

SIR.—No one could fail to appreciate the fundamental soundness of the Report of the B.M.A. Medical Curriculum Committee or of your eulogistic leading article (May 29, p. 1033); nor could one deny the wisdom of the "renaissance of the general physician." There is a considerable danger, however, that the pendulum may swing back too far, and that the real need that brought about specialization and specialists be too easily forgotten. Medicine has advanced very rapidly in the last twenty years and it is a most exceptional intellect that can cover the whole field of medicine and do justice to each section. As a general physician I have personally experienced the great benefit of the specialist's help in any intricate and progressive condition. The idea of relegating the specialist to the rarefied atmosphere of a hospital is also, I believe, an error, even though the specialist has been attained, yet I was equally convinced that the general physician should retain the right to make original contributions in the course of his practice. The specialist is a very definite place in the medical team, and his contributions are of one such type as to be completely outside his own field of competence (I am, etc., but I am not doing).

whose undergraduate pupils to-day occupy high places in his particular specialty in England and the Dominions.—I am, etc.,

London, W.1.

BRITISH MEDICAL JOURNAL

S. LEONARD SIMPSON.

SIR.—In the review of the Report of the Medical Curriculum Committee entitled "Medical Education: A New Approach" (May 29, p. 1040) I read that "the least suitable person to teach psychology is the old-fashioned member of the medical staff of a mental hospital, whose experience is confined to abnormal patients." Such a prejudiced view seems hardly worthy of the authors of this stimulating Report. It just is not true that the medical staff of a present-day mental hospital is old-fashioned. I should not have been altogether surprised to find criticism regarding ultra-modern ideas, but to suggest that mental specialists are behind the times is patently false.

The keynote at the present time of the professional outlook in psychiatry is progress, and this is abundantly evident in the reports of work done and in the papers and discussions in specialist circles. Psychiatrists have for long stressed that psychology, in conjunction with anatomy and physiology, should be taught to all medical students. It seems strange that those responsible for this Report should hold the opinion that the experience of those medical men and women who possess the D.P.M. is confined to abnormal psychology—a glance at the syllabus should be sufficient to change this opinion. It is, however, certain that it is not possible to draw any real distinction between normal and abnormal psychology as contrasted in this review.

Finally, surely it is time that the fallacy concerning mental hospital specialists' experience being "confined almost entirely to the treatment of psychotic patients" was abandoned. It can be stated without fear of contradiction that for the past twenty years more cases of psychoneurosis have been seen and treated in the out-patient clinics staffed by mental hospital psychiatrists than under any other conditions, and that under the Mental Treatment Act a high proportion of the cases admitted to mental hospitals are not "psychotic patients." Please let us agree that psychological medicine is a 'branch of general medicine and that psychiatrists are physicians first and mental specialists second.—I am, etc.,

Eisibourne, Sussex.

W. GORDON MASEFIELD

SIR.—Having always taken an interest in medical education, it was with particular zeal that I studied the summary of the B.M.A. Committee's report and recommendations for modification of the medical curriculum, and I am still trying to discover how the proposed medical training differs from my own training which commenced in London 20 years ago.—I am, etc.,

J. C. B. BONE.

National Hearing-aid

SIR.—May a hearing-aid wearer of many years' experience supplement the views expressed in your correspondence columns some weeks ago by commercial purveyors of hearing-aids (March 27, p. 619)? Mr. A. Edwin Stevens appears from his letter to imagine that sympathy with those whose hearing is impaired—or, to use his phrase, "emotional fervour on behalf of the deaf"—will necessarily hinder good service to them. Does he think that callousness on the other hand will lead to excellent service?

Every user of a hearing-aid who reads such an opinion will call to mind painful experiences showing how surprisingly this view has become established in the showrooms of many of the leading makers of commercial hearing-aids. Here are a few:

A wearer whose receiver had become detached from her lead-band as she moved her head while addressing a large meeting came to the maker and reiterated her previous request that headband and receiver should be firmly united. She was assured that if a hearing-aid headband becomes thus detached it is quite easy to refit it without removing the headband. (A woman's headband being worn under her hair, is awkward to remove in public.) She summoned courage to challenge the salesman to attach a receiver to a headband fixed on his own head, and only after he had spent some minutes in ineffectual attempts to perform this "easy" operation did he succeed in persuading him to adopt her device to fit her headband more firmly to the receiver.

Again, a prospective purchaser is usually fitted with a commercial aid in a small room with no objective test (such as the use of a standardized clock) to enable the purchaser to gauge the amount of improvement in hearing secured to him by the aid. After a minute's conversation assisted by an aid, he may slip it off and apologetically explain "Yes, but I am so sorry, I can hear you like this perfectly well without the aid, so I cannot really judge how helpful it is." There is no solution of this situation.

Or the patient may produce his own clock. The writer has many times received back an instrument which, no doubt, the mechanic believed he had repaired, but on testing her hearing with it on her small portable clock, she has found that the clock is no longer audible at the same distance as before. It has happened that an accidental tap to the microphone has then revealed that the fault lay in the one part of the instrument that the mechanic had forgotten to test!

To turn to Mr. Gee's first point—the excellence of the post-war British commercial aids. Unfortunately, the single instrument with the microphone incorporated, now being so widely offered, is utterly unsuitable for female wear, as even the smallest is too heavy to be clipped to soft garments and is only suitable for a coat or waistcoat pocket.

The handbag, for so long pressed on the woman wearer of a hearing-aid, is a device that inevitably leads to disaster to the woman who requires her hands. A little thought has led to a different method by which a woman wearer can forget that she is wearing an aid.

The writer (who is no physicist) has naturally been able with years of experience to devise remedies also for certain other inconveniences in the methods advised for wearing the current commercial instruments. She has taken pains to suggest to many makers (including the firm who supplied her own aid) that her devices should be offered to other clients, and has expressly renounced any wish for profit from them. Yet, though professional women have often exclaimed that these devices are exactly what they have often asked for in vain, never have they been proffered to them by the private makers.

In short, the care and consideration and "personal attention" (to use Mr. Stevens's phrase) normally available in the hearing-aid showrooms are about comparable to those of an optician (if such a person is conceivable) who should say to his client, "I have made you two beautiful lenses, but as for the question of the best way for you to wear them or what sort of frame you should use, you really cannot expect me to give attention to such purely mechanical matters."

It is unnecessary (though it would be easy) to adduce further examples from the experience of the writer and of her many partially deaf friends of the extraordinary lack of consideration of the needs of their clients by commercial makers of aids. It is clear that very great changes are required in the training of those who fit hearing-aids to new wearers and of those responsible for their maintenance. Surely there is good hope for such improvement as a result of the lone thought and experiment given to this matter not by "the Government" but by the persons with highest qualifications as well as "emotional fervour" whom the Government has wisely invoked through the Medical Research Council.—I am, etc.,

HEARING-AID WEARER.

Pain in Childbirth

SIR.—In the correspondence regarding pain in childbirth little reference has apparently been made to the possible biological value of such pain. Eugene Marais, the South African naturalist, has maintained that pain itself is the stimulus of the maternal instinct, just as scent in some animals and colour in others are the trigger stimuli for the operation of the sex instinct. "We find," he says, "that birth pain is the key which unlocks the doors to the mother love in all animals from the termite to the whale. Where pain is negligible mother love and care are feeble. Where pain is absent there is absolutely no mother love. During a period of ten years' observation I found no single exception to this rule." (*The Soul of the White Ant*, p. 111.) He supported this opinion by experimental proof with a herd of 60 half-wild Kaffir buck. In fifteen years he saw no instance of a mother refusing her young in normal circumstances. To six of them he gave an anaesthetic during labour, thereby abolishing the pain, and in all six the mother refused to accept the lamb of her own volition. In four cases he admini-

stered curare, by which consciousness was partly paralysed but not destroyed: the mothers were in doubt for over an hour, and then three accepted and one refused the lamb. To prove that the refusal was not due to the anaesthetic itself he let six mothers deliver their young normally and immediately afterwards anaesthetized them for half an hour. In all cases the mother accepted the lamb immediately she became conscious.

It is obvious from everyday observation that pain itself gives rise to physiological changes such as palpitation, sweating, and may even affect healing processes. There is some evidence to show that if pain is abolished under hypnosis the healing of a wound is accelerated (*Lancet*, 1917, 2, 678). There appears therefore to be no *a priori* reason why pain in childbirth should not act as a stimulus releasing the hormones or whatever it is which is the physical basis of the maternal instinct. If these views are correct they give support to those "misguided" mothers who prefer to have their babies without anaesthetic and to suffer the pain, claiming that it gives them more love for their offspring. This is often regarded as pure masochism, a perverted pleasure in suffering pain, but it may have another explanation, being nothing less than a biological fact. In view of the importance of this subject both for individual and social psychology, the very perpetuation of the maternal feeling depending upon it, further scientific investigation of the matter in human mothers is obviously called for before we launch on a wholesale administration of anaesthetics, to determine whether in fact there is any diminution of maternal devotion resulting from the complete or partial administration of anaesthetics in childbirth.—I am, etc.,

London NW1

J. A. H. FIELD.

Pulmonary Oedema

SIR.—May I correct a statement in the penultimate paragraph of the leading article on pulmonary oedema (May 29, p. 1035)? It reads, "In the latter connexion Daly has found that perfusing a heart-lung preparation of a dog with human blood causes the rapid development of severe lung oedema, though perfusion with horse blood keeps the lungs dry." Your leading article associates this statement with my paper in *Thorax*, 1946, 1, 182. If reference is made to this paper in *Thorax*, it will be found that the experiments were not carried out on the heart-lung preparation but on perfused dogs. These animals were anaesthetized and perfused in some experiments for as long as 8 hours, during which time the respiratory centre remained active. This perfused living animal (P.L.A.) preparation differs in many respects from the heart-lung preparation, for the heart is functionally excluded and is replaced by two blood pumps, the one for perfusion of the whole systemic circulation, the other for perfusion of the pulmonary circulation. By these means the blood flow through each circulation can be separately controlled and the physiological responses of each investigated without complications of changes in cardiac output. A full account of the P.L.A. preparation will be found in a paper by Daly, Elsdon, Hebb, Ludány, and Petrovskaia (*Quart. J. exp. Physiol.*, 1942, 31, 227). In this preparation Dr. Josephine Weatherall and I found that when horse blood is used as the perfusate the lungs remain dry, but when human blood (Group O) is used severe lung oedema occurs within fifteen to ninety minutes. Experiments of this kind, however, give no evidence that similar effects would be produced by horse and human blood on the lungs of heart-lung preparations. Such a result might be expected, but, as far as we are aware, the matter has not yet been put to an experimental test.—I am, etc.,

Cambridge

I. DE BURGH DALY.

Waiting for Tonsillectomy

SIR.—Mr. William Ibbotson (May 22, p. 1002) calls attention to the acute anxiety and distress of parents in regard to children whose tonsils cannot be removed because of the long waiting-lists for this operation at the hospitals. The waiting-lists are so long that "a desperate position has arisen."

I suggest that this intolerable anxiety of the parents (which is out of all proportion to the suffering of the children) can be greatly alleviated by reminding them that tonsillectomy has its dangers—e.g., it was estimated that in the days when the waiting-lists were shorter about 80 children lost their lives each year as a result of the operation.

By the time these possibilities are explained, the parents' anxiety becomes more tolerable and they may even listen to advice about more conservative methods of dealing with tonsil trouble.

Mr. Ibbotson's reference to "the utmost importance that healthy growth should be encouraged and not hindered" raises again the important question, Is there any proof that tonsils and adenoids retard physical growth or mental development any more than similar collections of lymphatic tissue in the sinuses or in the groins or in any other part of the body?—I

breath spontaneously during the course of the treatment, and sometimes, even with good curarization, do not stop breathing entirely.

It can be argued that a test dose of here as in surgery, but in a test dose of stress, anxiety.

It can be argued that a test dose of curare is as necessary as in surgery, but in psychiatric patients, where nervousness, anxiety, and sometimes extreme uncooperativeness are usual, such a routine is hardly practicable. The most difficult type is the heavily built, thick-necked patient in whom a uneventful recovery with a good colour is much more difficult to achieve, even with every device for acquiring a good airway and of careful ventilation. In such, the possibility of bronchospasm must always be borne in mind.—I am, etc.,
London, W.1.

STEPHEN COFFIN

Tolerance Limits to Radiant Heat

Tolerance Limits to Radiant Heat

SIR,—The article on this subject by Drs. D. L. Lloyd-Smith and K. Mendelssohn (May 22, p. 975) is to be commended as another step towards providing proper physical data and measurements for physical medicine in daily use for treatment. But, useful as careful measurement of the radiant flux of various apparatus is, it does not provide any justification for the inference in this article, particularly in the summary, that "under well-defined conditions, considerably higher intensities of radiant heat can be applied clinically than has been customary so far."

It was common knowledge during the established practice of treating by means of radiant heat, that the greater the intensity of the radiation, the more rapid was the effect. The fact that the tolerance limits are not yet known, does not justify the inference that they are higher than has been generally supposed.

Yours faithfully,
"STEPHEN COFFIN."

It was common knowledge during the war that the old established practice of treating shock and other allied conditions by means of radiant heat cradles was often liable to exacerbate the condition rather than ameliorate it. By all means let us know what we are doing physically when we apply radiant heat or infra-red to a patient, but it is clearly of greater importance to ascertain whether there is any real biochemical justification for the widespread application of radiant heat and infra-red, and, if so, in what doses and for what conditions it should be used. Simultaneously, steps should be taken to ascertain whether heat applied by methods of conduction or convection are, or are not, better in their clinical results.—I am, Sir, yours faithfully,
London, W.1.

ALFRED J. MARTIN.

Anti-Rh Serum Nomenclature

ALFRED J. MARTIN.

Anti-Rh Serum Nomenclature

SIR,—The use of two nomenclatures for the varieties of Rh agglutinogens, the corresponding antisera, and the underlying genes by the two groups of scientists who have contributed most to our knowledge of this branch of serology is to be greatly deprecated. The use of both designations simultaneously, as proposed by the National Institute of Health in the United States, has not been accepted by either side, and Wiener has enumerated the reasons why he objects to this compromise (April 24, p. 805). Only a few of these objections are, however, justified. It is certainly a disadvantage that Fisher's system does not make the relationship to the Rh factor clear by appropriate lettering. The "one-to-one correspondence" of genes and partial antigens is definitely hypothetical but not essential for the use of the nomenclature.

As I have pointed out previously, reactions need not be a mixture. Instead of the three

As I have pointed out previously, the types of serological reactions need not be a mirror image of the antigenic structure. Instead of the three linked partial antigens there is a possibility of a single molecule with a common nucleus and three more or less different side chains. The genetic conception of Fisher may, however, gain support by a more detailed knowledge of the frequency of such mutations as could be explained by crossings over (Race). The designations as could be explained by crossings over for variants of partial antigens such as C, Cw, Cu, etc. Thus new discoveries were easily incorporated into the Fisher system, while Wiener found it necessary to change his designations repeatedly. In addition, the use of such designations as Rh⁺ with not an analogous meaning to Rh⁻ and Rh⁺ is misleading. Essentially, however, both systems are identical and a glance at tables in papers by Wiener, Race, Mourant and associates, or in Bessis' monograph, will show that each designation in Fisher's system has a synonymous one in Wiener's, or vice versa. A compromise in the form of a synthesis is therefore possible by replacing the circle and strokes in Wiener's system by Fisher's lettering.

We propose, therefore, that the phenotype be designated by the letters of the sera used in testing added to the statement Rh⁺. The principle is the same as that proposed by Murray.

R. P. GARROW.

Electro-narcosis
May 20

R. P. GARROW.

Electro-narcosis

Sir Your report (May 29, p. 1044) of my lecture at the Royal Society of Medicine on May 11 contains four errors which call for correction.

- The dose of atropine which I recommended was 1/60 gr. (1 mg.) and not 1.6 gr. (11 mg.) as stated.
- The statement "... it was rare to give less than 200 f/A for the first 30 seconds..." was rare to give the first 30 seconds... ..

- 1 The dose of atropine which I recommended was 1/60 gr. (1 mg.) and not 1.6 gr. (11 mg.) as stated.
- 2 The statement "it was rare to give less than 200 f/A for the last 30 seconds"
- 3 The

2 The statement "it was rare to give less than 200 f/A for the last 30 the first 30 seconds"

- 1 The dose of atropine which I recommended was 1/60 gr. (1 mg.) and not 1.6 gr. (11 mg.) as stated.
- 2 The statement "... it was rare to give an application of less than 200 f/A for the last 30 seconds" should read "for the first 30 seconds."
- 3 The sentence "In 8 cases of severe psychoneurosis there were two striking recoveries" gives a wrong impression, for 7 out of the 8 patients recovered or were much improved, two being cited in detail.
- 4 Mr Grey Walter suggested that the term "..." would be more suitable a title than "...", with which I agreed.

4 Mr Grey Walter suggested that the term "Electro-coma" would be more suitable a title than "Electro-narcosis," a view with which I agreed. His reference to electro-delirium was scarcely meant to be taken seriously.—I am, etc.,

A. SPENCER PATERSON.

Sir In the report (May 29, p. 1044) of the discussion on May 11 in the Section of Psychiatry at the Royal Society of Medicine at which Dr. Spencer Paterson showed a film of electro-narcosis, Dr. Gerald Caplan advocated a dose of pentathal 0.3-0.4 g. (with atropine) and of *d*-tubocurarine 12-15 mg. before electro-narcosis.

I have been collaborating with Dr. Spencer Paterson in such cases as an anesthetic for over a year, and I have found that while in E.C.T. pentothal 0.3-0.4 g. with atropine gr. 1/60 (1 mg.) added—rapidly given, can be an adequate dose, 0.5 g. is usually more satisfactory. Particularly in electro-narcosis. One has to remember that having allowed three minutes for the curare to take effect, the electro-narcosis will continue for another seven, and that before the total ten minutes has elapsed some patients may easily be sufficiently light, to remember, if for some reason the current has intentionally been less than usual. I have known this to happen. In ECT I usually give pentothal 0.4-0.5 g. (Seldom 0.3 g.), and in electro-narcosis 0.5-1.0 gm. (0.8 g. and I find that with the greater dose one obtains a better balance between the speeds of recovery of the pentothal and the curare.

As regards curare dose, I have this on 2 mg. of curare (between 1 and 2 mg.) with a reduction of 0.5 mg. for every 10 minutes in duration of the electro-narcosis.

and I find that with the greater dose on the balance between the speeds of recovery of the curarizing and the curare. I base this on 2 mg. of *d*-tubocurarine with a reduction in dose for fat patients. A second treatment can be made at the second treatment with a little shift and often unnecessary. Good curarization by no more movement than slight flexion of the trunk and only very gentle movements of the trunk and arms is possible, but even with good curarization the patient is unable to cause a loss of good colour with the current is switched.

...the current is switched
...of good colour with

...patients begin to

Presented herein to

(2) But the agenda technique is recognizing something of a danger. It makes all the difference in the world what sort of meat you put

I offer this rough analysis of causes and invite your readers' critical consideration of a problem which concerns us all very nearly. May I now suggest certain remedies?

Overcrowding.—Since the hall cannot be enlarged, it follows that the number of representatives must be limited; and this can only be achieved by reducing the proportion of representation, so that Divisions elect one representative for every 120 members instead of for every 100. This would make proper seating arrangements practicable.

The length of the agenda cannot properly be limited. Therefore the time allowed must be greatly extended. If necessary, the expenses of provincial representatives should be more liberally covered, and since hotel accommodation is so difficult I would strongly commend the suggestion that we in the London area should offer, and obtain in our Divisions, hospitality for provincial members. No representative should have to come straight from a night train to attend an all-day meeting.

The Agenda Committee is a very necessary body. Its constitution should be altered so that it derives at least half its membership from the body of the hall.

The Secretariat.—The profession must look to the Council to see that no undue influence is exerted upon policy by the whole-time officials of the Association.

The Platform.—Many of the difficulties of speakers would disappear if more time and leisure were available and the rush and hecticness of proceedings were reduced.

The Council.—One is filled with admiration for the patient and conscientious way in which members have discharged their exacting and arduous duties. Many of us believe that they have made disastrous mistakes in the last few months, but we are insufficiently informed. Perhaps the most useful general suggestion one can make to them is that they should take the R.B. more fully into their confidence. Nothing can do more harm to the unity of the profession than an apparent attempt to blanket criticism. On the other hand, the R.B. should use more imagination and ask for information instead of putting down ill-informed motions of censure.

The representative himself is a very responsible person. It is obviously very necessary that he should do his best to keep in touch with all the members of his Division, explaining major issues to them and ascertaining their opinions. He is, surely, wrong to come to Representative Meetings with a closed mind, slavishly bound to abide by the decisions reached upon incomplete evidence at his Divisional meeting. He must make it perfectly clear that he will use his discretion in interpreting their views in the light of any new information that may come to him; and if his Division does not accept that concept of his duty, he should resign.

He will probably find that Divisional meetings will be better attended if more care and forethought are given to the preparation of the agenda accompanying the notice of meeting. The choice of day and time is important, and in large and scattered Divisions it may be well worth while to hold group meetings at local focal points within the area instead of trying to assemble the whole Division at one place. Divisions should appoint deputy representatives and these should take part in local organization.

Minorities.—Some way must be found of securing representation for the minority view. I believe the best plan is as follows:

(1) Larger Divisions with two or more representatives should elect one of them with the specific duties of ascertaining the views of substantial minorities and voicing them at the Representative Meeting.

(2) Smaller Divisions should ask their representative to make sure that all views are presented, giving some indication of the size of the groups.

(3) The Representative Body should appoint officially one or more "watch-dogs" whose function is to assist representatives to understand the views which are in opposition to the majority view of the Council. They should be entitled to attend meetings of the Council and to take part in its debates.

(4) The "watch-dogs" should be out of place at Representative Meetings. We are a scientific body, concerned to find the truth. We should not be like the familiar methods of scientific argument, which are to discuss radical politics?—I am,

A. C. F. BRIDCH.

Views of Marylebone Division

SIR.—The remarks made by Mr. R. L. Newell about the Marylebone Division at the recent Representative Meeting did not seem to me of much importance when they were made, but now that they have been elevated to the prominence of a leading article (June 5, p. 1086) I hope you will allow some comment from one who has had the honour to be chairman of that Division for over two years. Mr. Newell speaks of "the acute symptoms developed in the Marylebone Division." To talk thus of a policy which has been absolutely constant for over three years is as ridiculous as it is to suggest that Lord Horder's views could be "warped" by those of anyone else. Mr. Newell evidently wished to give the impression that there had suddenly sprung up in Marylebone a sort of hysterical condition that was at complete variance with the views held in the rest of the country. May I give a few examples to show how incorrect he is?

Over a year ago, when the Representative Body was considering the Council's motion to authorize negotiations with the Minister provided that further legislation was not excluded, only 17 votes were cast against the Council; these 17 included those of the 7 Marylebone Representatives. Dr. Dain has since stated publicly that he is quite certain that the Minister in accepting negotiations had not the slightest intention of amending the Act. More recently, when the Council were hastening their plans for the last plebiscite, our Division felt strongly that there was far too much haste and insufficient time for discussion. Those members of Council who come from Marylebone fought hard for some postponement, but the vote went against them. However, it was confirmed at the recent Representative Meeting that our view was held by a majority throughout the country, for a motion from Newcastle-upon-Tyne that the plebiscite was premature was carried—a fact to which no reference is made in your leading article surveying the meeting.

We hold that "the freedoms of the profession are not sufficiently safeguarded." It seems to have been overlooked that this was also the Council's view. The fact that these most important words came to be tucked away in a long paragraph at the end of the document issued by the Council to every member of the profession can only have been by accident or design. If by accident, then a very serious error was committed; if by design, then something much worse. So far from our policy being one of acute symptoms, I submit that it has been consistently directed to one end—the best possible National Health Service for the public and the profession. It is still the same, and it is not influenced by the fact that others may think we have gained a victory; nor do we consider that because we have forced Parliament to take an exceptional course it is sufficient excuse to "call it a day."

So much for the past. What of the future? The more we may feel we have been weakened by over-hasty and ill-judged action, the more it is imperative that we should stand together. I am afraid it will not be long before the folly of these recent actions is manifest to all. We shall soon run into trouble. How we shall fight it, in our greatly weakened state, I cannot at the moment see; but, if we all stand together—those who agree with what has been done and those who do not—in the ranks of our Association, we shall fight it somehow.—I am, etc.,

R. HALE-WHITE,
Chairman, St. Marylebone Division

* The leading article referred to "the criticisms levelled against the Council and expressed in a motion which was carried deploring the holding of the April plebiscite."—ED., B.M.J.

The Special Representative Meeting

SIR.—As a representative of the Reigate Division I was asked to put before the recent S.R.M. two motions, one advocating the postponement of the appointed day, and the other expressing loss of confidence in the B.M.A. Council. Through no fault of my own, however, I was not allowed to bring forward these motions on behalf of my Division, nor, although I gave my name to the chairman of the meeting and asked to speak, was I given the opportunity to make my points under cover of other motions.

CORRESPONDENCE

JUNE 12, 1948

Had I had the opportunity, I would have drawn attention to the fact that, in the leading article of the B.M.J. of May 1 (p. 839), a statement is made that the Representative Body voted in favour of the 100% issue. The fact is that at the S.R.M. in May, 1945, a resolution was carried to the effect that the Association was willing to negotiate terms and conditions for a 100% service, provided that ample safeguards were introduced to ensure that any member of the community, whatever his income, should be entitled to obtain his medical service, in part or in whole, privately, as, for example, by grant-in-aid provisions. This, the policy of the B.M.A., has never been rescinded: I therefore hold that the B.M.A. is not in favour of an unqualified 100% service and that the leading article is misleading.

Further, my criticism of the Council is that, if the Council had studied the minutes of the S.R.M. of March, 1948, it should have realized that the resolutions carried at that meeting demanded the rejection of Mr. Bevan's "concessions" as quite inadequate. Those resolutions requested: (1) Postponement of the appointed day; (2) introduction of a national health service by stages; (3) no agreement as to terms by consultants or general practitioners until both sections who remain satisfied; (4) no penalization of doctors or patients who remain outside the National Health Service. Is it to be wondered, then, that I should feel that the Council has not carried out the policy of the Representative Body, of which it is the servant, and that as a representative my services are of no further value to my Division? I have therefore informed the secretary of my Division that, although recently re-elected, I feel I cannot attend the next A.R.M.—I am, etc.,

C. E. BEARE.

Dorkins, Surrey.

* The statement in the leading article to which Mr Beare refers was as follows: "We must, too, remind ourselves that the B.M.A. has declared its 'whole-hearted desire' for a comprehensive medical service available to everyone in Britain. The Representative Body voted in favour of the 100% issue." The following recommendation by Council was put to the S.R.M. on March 17 this year, and was carried unanimously (Supplement, March 27, p. 49):

That the Representative Body, reaffirming the whole-hearted desire of the medical profession for a comprehensive health service available to everyone, urges that in the public interest such changes should be made in the National Health Service Acts of 1946 and 1947 as are necessary to maintain the integrity of Medicine and to prevent doctors being turned into State servants, with harmful consequences to patient and doctor alike. The Representative Body therefore expresses the hope that the Government will make it possible for the profession to co-operate by making such changes, and states its view that it is not in the best interests of the public or of Medicine for members of the profession to enter the Service until such changes are made. (Our italics)

The "ample safeguards" referred to in the resolution carried at the S.R.M. in May, 1945, have been granted: medical practitioners within and outside the National Health Service are allowed to conduct private practice. Since the S.R.M. in March this year, to which Mr. Beare also refers, the Minister of Health has made a number of concessions on and after April 7 which the S.R.M. on May 29 considered were sufficient to justify the passing as a motion of recommendation A put before it by the Council (Supplement, June 5, p. 154).—Ed. B.M.J.

Trade Union Status

Sir.—Though it is quite unnecessary to reaffirm the adage at "united we stand, divided we fall," we seem as a profession at this moment to be both divided and falling. Having recently sat through five hours of discussion on the N.H.S. among local practitioners, the only impression I came away with was one of complete and utter confusion. Something is very wrong indeed in a situation if, at this eleventh hour, such confusion exists. Surely we must have an entirely new conception of unity if we are not to be picked off and enmeshed—still talking about freedom—by Mr. Bevan on July 5.

In these days of universal franchise the paradox is that individual freedom simply does not exist. We as a profession must either submit to the authority of the Minister of Health, or we must submit to that of our freely elected representatives. The Representative Body, as it is now constituted, has no real

authority and therefore no real power, and no real status in Mr. Bevan's eyes. The grave political blunder of the latest plebiscite would seem completely to have discredited those in control at Headquarters in the eyes of the rank and file, so that we are left with a headless body.

Surely the most urgent and pressing need of the moment is an election of a fully representative body with complete authority of decision, the confidence of the profession, and full trade union status. Only such a measure can guarantee a satisfactory N.H.S. with acceptable terms of service and remuneration, and only such a body can hope to compete on equal terms with the present or any future Ministry of Health.—I am,

E. P. JOWETT.

Okehampton, Devon.

Terms of Remuneration

Sir.—I should like to reinforce the arguments of Dr. Desmond Longford (May 22, p. 1004) regarding remuneration, though his figures are too favourable. If the ratio of population to general practitioners is 2,000:1, it follows that for each doctor who has a list of 4,000 (£3,332) three other doctors will have to oblige him by limiting their lists to approximately 1,400 (£1,362). These figures assume that everyone will choose his doctor by July 5, but a little thought will show that this is not to be expected. Many people are not doctor-conscious and will do nothing until they are ill and this type of person may easily total 40% at the end of the first year.

The Ministry pamphlet "Remuneration of General Practitioners," April, 1948, states in relation to persons not on a doctor's list that one-third of their money will be included in the pool. This amount obviously should be the whole, as it was in the panel days. The doctor who feels fairly sure of a list of 4,000 must reckon on the competition which will surely come when bronze plates appear around him bearing the names of starving practitioners from the seaside, where in many places the population is less than 1,000 per doctor.

I think that these considerations should be submitted without delay to the economic expert who advised us on panel capitation fees in 1946. Doctors who have signed on the dotted line already would do well to send a letter making clear that their acceptance of the new Health Service assumes the implementation of the Spens Report and disagrees with the Minister's remuneration.—I am, etc.,

ROBERT SLATER.

Preston, Lancs

POINTS FROM LETTERS

Extreme Disappointment

Dr. F. O. TAYLOR (Coldingham, Berwickshire) writes: Owing to the amazing collapse of the Association I have had to accept service under the new Act. But I have done so with reservations, which I have clearly stated on my Form E.C.16. I must record my extreme disappointment at the outcome of all our struggle and worry and expense of all kinds. We shall see within a short time that we are delivered defenceless to whatever system has been devised behind the façade of the National Health Service Act. Let's all sing "The Red Flag."

Standard Notepaper

Dr. J. S. LAURIE (Fitzwilliam, nr. Pontefract) writes: May I again use your columns to appeal to hospitals and private consultants to assist the general practitioner by using a standard size of notepaper which will fit neatly into the N.H.S. record envelope, which is the same size as the old N.H.I. model? It would present no difficulty for hospitals to order their stationery in what is known to printers as large post 6mo, either as folded folio or cut single, which would provide large and small sheets to fit into a tidy file and prevent the ugly, untidy, bulging mass of assorted sizes of notepaper which disfigure many of our record envelopes to-day. . . .

Encouraging Absence from Work

Dr. M. R. SONI (Manchester) writes: Many benevolent employers and corporations are in the habit of making up their employees' wages to the normal amount during a period of illness. It is a nice gesture, but as the practice in my opinion leads to prolonged absenteeism it is time something was done about it. Lots of doctors' time is wasted by issuing sickness notes to these well-to-do malingers, and if the income tax authorities insisted on treating these payments as personal gifts the practice will soon stop.

Obituary

C. S. THOMSON, M.D., D.P.H.

Dr. Charles S. Thomson, who died at his home in Ayr on May 30, was medical superintendent officer of health in Belfast from 1928 to 1945.

Charles Samson Thomson was a native of Ayr, and graduated at Glasgow University in 1906, taking the D.P.H. and the B.Hy. in 1908 and proceeding M.D. in 1912. Before coming to Belfast he held appointments as medical officer of health at Workington, Cumberland; Hyde, Cheshire; and Deptford, London. He was a Fellow of the Royal Institute of Public Health and Hygiene, and a member of the Royal Sanitary Institute. When he received the degree of doctor of hygiene at Durham University in 1938 he became the seventh person to hold that qualification. In 1937 he received the "Smith Award"—a bronze statuette of Hygeia—given triennially by the Royal Institute of Public Health and Hygiene to the medical officer of health who, in the opinion of the council, had in the discharge of his duties been responsible for the most noteworthy work in the department of preventive medicine. Dr. Thomson served with the R.A.M.C. as a bacteriologist in the 1914-18 war, and in appreciation of his services in Salonika during the Balkan campaign the Greek Government awarded him the Order of Military Merit of Greece. Dr. Thomson was a lecturer in public health administration in the Queen's University of Belfast, and contributed several papers on public health subjects which were published in professional journals. He was known in public health circles in all parts of the British Isles, and took an active interest in all branches of public health work. He attended many health conferences, where he frequently took part in the debates and discussions. He was a fluent speaker and had the happy faculty of expressing his remarks in a humorous vein. He was enthusiastic in all his work and did much to improve the various health services for which he was responsible.

Dr. Thomson was a man of genial disposition, kind and considerate, and with an aptitude for making friends. He was held in high esteem by the members of his health authorities and his colleagues. His retirement in 1945 was marked by the presentation of an illuminated address by his staff in the Belfast Public Health Service.

Mrs. Thomson predeceased him in 1944. His son, Dr. Charles S. Thomson, is a graduate of Queen's University and holds an appointment as medical officer of health at Dereham, in Norfolk. His son and other relatives are assured of the deep sympathy of his many friends and colleagues.

A. W. SIKES, M.D., F.R.C.S.

Dr. Alfred Walter Sikes was born at Ballycogley Castle, Co. Wexford, on July 9, 1869, and died at his home at Portscatho, Cornwall, on May 25 at the age of 78. He was educated privately and went to St. Thomas's Hospital with an entrance scholarship. He proved to be one of the most brilliant students of that hospital, winning the Tite and Peacock scholarship, and earning gold medals in both the intermediate and final examinations for the M.B. He also held the Treasurer's gold medal, the Barstow medal, and the medal in medicine. He proceeded M.D. in 1898, taking the F.R.C.S. in the same year, and in 1900 he was medical registrar to St. Thomas's. He had a great reputation among his colleagues and the public. His colleagues remembered him with affectionate awe on account of his stern capacity and mordant wit. After taking the M.B. and F.R.C.S. and the D.P.H. in 1901, Dr. Sikes took appointments of physician at Marburg University, and afterwards of lecturer in physiology at King's College, London. He wrote a number of original articles on this subject, and was active in the professional and technical journals. He proceeded D.Sc. in 1908.

Dr. Sikes was interested in, and helped to promote, the claims of social medicine. He was a member of the late Dr. James Kerr in the London County Council as a member of the original divisional

medical officers. He thus had a great share in the development of social medicine in London. He remained in charge of the North-Western Division of the London School Medical Service until his retirement in 1935.

In the first world war he volunteered for active service, and was surgeon to an ambulance train in France. After his retirement from the school medical service Dr. Sikes lived quietly in Cornwall, where he indulged his great love of gardening. His great mental gifts, combined with his pungent Irish wit, made him a most entertaining, if sometimes disconcerting, companion, while many of his former colleagues remember the ostentatious acts of kindness arising from that warmheartedness which was another characteristic. Sikes married in 1902 Miss Maitland, daughter of Thomas Townshend Somerville, of Copenhagen, and had two sons, one of whom survives him.

Dr. ALEXANDER GIBB GLASS died on April 21 at Grantown-on-Spey, Aberdeenshire, where he had been born seventy years before and where his father had been Provost. He had returned to his native town only two years before his death. Educated in Grantown, he went to Aberdeen University and graduated M.A., and then to Edinburgh University, where he took the M.B., Ch.B. in 1904. He worked in South Wales for two years as an assistant in general practice. He then decided to take up public health work, and so he proceeded M.D. and took the D.P.H. in 1908. His first public health work was in Roxburghshire, and after other appointments he finally became in 1921 M.O.H. of Farnworth and Kearsley, Lancashire. Here there was much to be done, and he tackled it with zest. The 1930 Housing Act gave Dr. Glass the authority he needed, and in spite of much local criticism he condemned property and cleared the town of slums. In 1941 he was a proud man when he was able to record an infant mortality rate of 43 per 1,000, the lowest figure in the town's history and lower than the average for England and Wales. In 1943 he retired after twenty-two years' successful work in the town. Dr. Glass was always efficient, but he had a very kindly manner, though his kindness did not prevent his taking a firm stand for truth at right living. He knew well just how much a good home meant to the moral and physical well-being of the community. Dr. Glass had been a member of the B.M.A. for many years, and he was Chairman of the Bolton Division in 1934-7. He leaves a widow, to whom we offer sympathy in her great loss.—J.M.S.

Dr. WILLIAM ARTHUR BRUCE YOUNG died at Market Drayton on April 24 at the age of 72. A graduate of Manchester University, where he qualified in 1900, proceeding M.D. in 1914, he came to Winchester in 1917 as medical officer of health, school medical officer, and physician in charge of the fever hospital. The chief interest in his life was his work, and he devoted himself to it wholeheartedly. Dr. Young never spared himself even when he was hardly able to perform his duties on account of the asthma from which he was rarely free during the last years of his professional life. Dr. Bruce Young was an extremely conscientious man. In the fever hospital he inspired confidence in all his patients and was held in the highest esteem by the matron and nursing staff. In the same way he was the friend of all the children he looked after in his school work. He was a good organizer and inspired both loyalty and affection in the members of his lay staff. He was a well-read, cultured, and courteous man. His hobby was the collecting of "Baxter Prints." Although professional work claimed so much of his time yet he was able to take an active part in the affairs of the British Medical Association, of which he was a member for thirty-five years. During this period he held the following offices in the Winchester Division: chairman, 1923-4 and 1934-5; honorary secretary, 1924-8; 1929-32; acting honorary secretary, 1933; and representative in the Representative Body, 1939. Dr. Young retired in 1941 to Market Drayton. Just before he died he was planning to visit Winchester again for a short time to see some of his friends. His passing will recall to those older practitioners in Winchester who were privileged to know him many memories of his help and kindness. His marriage was a most happy one and he leaves a widow and a son.—R. H. B. B.

Dr. GEORGE MCCONNELL, of Carnoustie, died on April 11 after a brief illness. A native of Northern Ireland, like many others of his countrymen he studied medicine at Edinburgh University, where he gained the Allan Surgical Prize and graduated M.B., Ch.B. in 1912. He was house-surgeon to Alexander Miles in Edinburgh Royal Infirmary, and thereafter

Pre-operative skin sterilisation

In thoracic surgery, gynaecology, dermatology and wherever a sterile field is required, VIACUTAN, a highly potent bactericide, is a particularly satisfactory agent. VIACUTAN is non-irritant, has remarkable powers of penetration into tissue and stimulates healing. VIACUTAN can be applied freely and with impunity inside the pleural cavity, to large surfaces of muscle and fascial planes, to wounds and burns, and is used for cleaning out sinuses and tracks.

The editor found
it beneficial to
his circulation...

In normal health, an editor thinks of his 'circulation' in terms of net sales. In altered circumstances, he may be preoccupied with that other circulation which concerns the movement of his blood.

Circulatory and cardiac insufficiency are among the conditions for which Corvotone is eminently suitable. It is also recommended in cases of post-anæsthetic collapse, narcotic poisoning and asphyxia. Corvotone is administered orally in chronic and mild conditions. In more serious cases, it should be given by either subcutaneous or intravenous injection. Consisting of a 25 per cent. solution of Nikethamide, Corvotone is one of the most potent analeptics. It is non-toxic, and does not give rise to undesirable reactions. Available in boxes of 3, 6 and 100 ampoules of 2 c.cm.

'FISSAN'

**ANAL OINTMENT
AND SUPPOSITORIES**

*for the local treatment of
Haemorrhoids and Anal Fissures*

Haemorrhoidal conditions require the following qualities in any preparation applied:

1. Stemming of hæmorrhage.
2. Relief of pain and irritation.
3. Reduction of mucous exudation.

In all cases 'Fissan' treatment will clear up the trouble, and in severe cases may be used to give relief and create suitable conditions for the resolution of the varicose condition.

'Fissan' Anal Ointment and Suppositories contain menthol to soothe pain and irritation, witch hazel and zinc oxide to reduce inflammation, kaolin to absorb exudation, boric acid and zinc oxide to exert an antiseptic action, and colloidal milk protein to soothe the tissues.

'Fissan' is available in a fine state of sub-division, thus assuring penetration into the smallest area available. The medicament is applied directly to the affected area upon application.

BURROUGHS WELLCOME & CO. (The Wellcome Foundation Ltd.) LONDON

Hepolon is produced by special processes which conserve all the known hæmatopoietic principles of the whole liver. It approximates to the extract described by Gänsslen.

Hepolon not only passes the highest clinical tests for potency against pernicious anaemia but contains Whipple's factor, Wills's factor, riboflavine, nicotinic acid, and the hæmatinic minerals of liver; it gives no reactions for histamine or undesirable protein matter.

Ampoules of 2 c.c.; box of 6, 6/6; box of 12, 11/6; and box of 24, 22/6.
Rubber-wrapped vial of 10 c.c., 5/6; and of 30 c.c., 12/6.

HEPOLON

Equivalent to 100 c.c. the total soluble extractive matter of 250 g. fresh liver.

ALLEN & HANBURY LTD. LONDON. E. 2

studied midwifery at the Rotunda Hospital, taking the Dublin L.M. He served with a Highland Division Field Ambulance on the Salonika front in the war of 1914-18, and then settled in Carnoustie, where he had a large practice in the town and surrounding rural area, which occupied his whole day and often a great part of the night. Dr. McConnell was an excellent diagnostician, and his opinion, based on an intimate personal knowledge of the patient, was sound and accurate. His kindness to and consideration for his patients was boundless. During the recent war he never had a holiday. Even his great physique—he was an Irish rugby international forward—gave way under the strain and he carried on till he collapsed at his work. The whole community paid their last tributes in St. Stephen's Church and at the graveside on April 27. He is survived by his widow; by a son, Dr. Desmond McConnell, who served with the R.A.M.C. in the recent war and became a partner in the practice after demobilization a year ago; and by a married daughter, who is also a medical graduate.—R. C. A.

Dr. ARNOLD WHITAKER OXFORD died on May 30 at the age of 93 after an unusual medical career. Dr. Oxford was born at Keynsham in 1854, and after graduating at Oxford University he was ordained in the Church of England. Interesting himself in social problems, after some years he became a medical student at Charing Cross and the London Hospital. He qualified L.S.A. in 1897, going on to take the M.B. of his own university in 1898 and proceeding M.D. a year later. He especially devoted himself to the reclamation of prostitutes, and took consulting-rooms in Bond Street with a view to healing their bodies as well as their souls. At the same time he worked untiringly in the service of the Samaritan Free Hospital for Women, where he was for many years chairman of the board. During the first world war he went back to Charing Cross Hospital as an honorary resident medical officer, acting in that capacity from 1917 to 1924. As an all-round practical philanthropist his record will not easily be beaten.—H. R.

Dr. JOHN MACMYN died at his home in Kirkcudbright on May 13 at the age of 85. A native of Bargrennan, Newton-Stewart, Dr. MacMyn received his early education at the Ewart High School. At Edinburgh University he graduated in 1884, and proceeded M.D. in 1890. He settled in Kirkcudbright immediately after qualifying. At that time there was no telephone, no hospital in the burgh, and no means of visiting patients in Twynholm or Dundrennan except on foot or horseback. He started as an assistant to the late Dr. William Johnstone and had been in general practice continuously for over 64 years. In recognition of his devoted service Dr. MacMyn was made a freeman of the Royal Burgh of Kirkcudbright on his eighty-fifth birthday—less than six months ago. It was said then that he had never taken a holiday except once in 1913 when he was away from his practice for three days. Dr. MacMyn will be greatly missed by his colleagues and his many friends and patients. His only son, Dr. David MacMyn, the former Scottish rugby international, will succeed him in the practice.

Dr. JOHN HERBERT HANNAN died suddenly on April 7 at the age of 50. He joined the R.A.M.C. in 1939, but had to resign his commission on grounds of ill-health after only a few months' service.

Dr. Eric Coplans writes: John Hannan was the son of the late Herbert Hannan, a consulting engineer. From Merchant Taylors' School Hannan went up to Downing College Cambridge. Qualifying from St. Bartholomew's Hospital in 1921, he studied in Vienna and Paris, working at the Pasteur Institute. He graduated in 1926, and proceeded M.D. a year later. From the time of his appointment as registrar at the Sono Hospital for Women he devoted himself in the laboratory, theatre, and in practice to the study of women's diseases. Much of his work is recorded in monographs and in the medical journals. He worked at the physiological laboratory (Middlesex), under the aegis of the B.M.A., on ovarian transplantation. Equally outstanding were his monographs on the flushing of the menopause, epinephrine sensitiveness at the menopause, and adrenaline effects at the menopause. He was the rare combination of research worker, pathologist, and surgeon, and it was only his persistent ill-health that prevented him from attaining the greatest heights in his profession. He was a fine classical scholar, a man of catholic tastes and culture, and of fearless outlook. We who loved him will remember him most of all for his courageous battle against his grievous ill-health, and for his utter unselfishness. He served throughout the London blitz and was wounded in the leg, concealing his injury till he dropped. It was during the Battle of Britain that he met his wife Monica, a trained nurse, who survives him.

Medical Notes in Parliament

RECOMMENDATIONS OF SPENS COMMITTEE

The Minister of Health, Mr. Aneurin Bevan, and the Secretary of State for Scotland, Mr. Arthur Woodburn, on Friday, June 4, presented to Parliament the report of the Interdepartmental Committee on the Remuneration of Consultants and Specialists.

The Government has accepted the recommendations in principle. Announcing this in the House of Commons on June 3, the MINISTER OF HEALTH added: "The task of evolving from it the best scheme of actual remuneration, to suit all cases—and especially the hearing of the recommendations on remuneration for teaching duties—will be difficult and will require the help of the profession in discussion. I propose to begin this quickly, but whatever final scheme emerges will be deemed to operate from July 5, even if discussions carry us past that date. Meanwhile, interim contracts will be offered to specialists."

Appointed in May, 1947, this Committee, under the chairmanship of Sir Will Spens, was asked to recommend what ought to be the range of total professional remuneration of consultants and specialists in any publicly organized hospital and specialist service. The Committee's report is published at p. 1145 of this issue and is the subject of a leading article at p. 1140.

CRIMINAL JUSTICE BILL

After a two-day debate the House of Lords, in Committee on the Criminal Justice Bill, deleted the clause inserted in the Bill by the House of Commons for the suspension of the death penalty for murder. The deletion was carried by 181 to 28. The House also authorized the retention of flogging as a penalty while debarring the use of the cat-of-nine-tails.

NURSERIES AND CHILD-MINDERS

In the House of Commons on May 28 the Nurseries and Child-minders Regulation Bill was read a second time without a division. Mr. JOHN EDWARDS, for the Ministry of Health, explained that the Bill is to provide for the regulation of nurseries where children are looked after, either for the day or for the day and night during the working week, and of persons who for reward and in their own homes looked after children under 5 while their mothers were at work. He explained that registration and supervision would be limited to persons who minded children as a business and not to the relative or friend who looked after one or two children while the mother was at work.

PURCHASE TAX ON DRUGS AND MEDICINES

When the Finance No. 2 Bill was considered in Committee of the whole House on June 2, Mr. OSBERT PEAKE moved an amendment to Clause 19 (New Purchase Tax Rates). He said he did so to raise the whole question of the purchase tax on drugs and medicines and on the proposed discrimination for the first time between branded and proprietary medicines and non-branded and prescribed articles. His amendment proposed, along with subsequent amendments in the same series, that all drugs and medicines of whatever character should be exempted from purchase tax.

Before the introduction of the recent Budget, Mr. Peake said, all drugs and medicines were subject to this tax with the exception of certain costly or essential drugs which were exempted by Treasury Order. Under the Finance Bill some drugs and medicines were subject to 33½% duty, but two other classes of drugs were exempted altogether. The container of an exempted drug or medicine might contain directions as to use, but it must not mention what the medicine was to be used for. To describe it as a cough mixture or a laxative would immediately render the goods liable to purchase tax. The name and address of the maker, seller, supplier, and distributor of the goods could be given if in letters no larger than the letters which gave the chemical formula. He gave examples of substances which would be taxed and of others precisely similar which would not be taxed. If a customer asked the chemist for a bottle of "California syrup of figs," he would have to pay 33½% purchase tax. If on the other hand he asked for "compound syrup of figs B.P.C." he would escape purchase tax. He contended that trade marks, names, and brands protected the public by being a guarantee of quality. The public were not familiar with the scientific names and designations found in the British Pharmacopoeia and were therefore liable to use the wrong remedy because in order to avoid tax the

on research and advertised only to the medical, dental, and veterinary professions.

Mr. GAMMANS said the export trade in proprietary medicines was estimated to be worth, this year, £8,500,000. Surely it could not afford to meddle with a trade which was so successful? These medicines sold abroad because their trade had been established in the home market.

Mr. DOUGLAS JAY, replying for the Government, said the clause did not raise the tax on any of the Government proprietary medicines still paid for by the public. The Government intended to aim at abolishing the tax on all proprietary medicines described in public lists.

Export Trade

Mr. J. Lewis said proprietary medicines sold under brand or trade mark were manufactured not only for the home market but also for export. In 1947 these proprietary medicines were exported to the extent of nearly 425% of the 1938 value, and since then the target had been increased to a further 40% above 1947. People who were accustomed to using branded articles would not go to the trouble of asking for the chemical equivalent. Chemists, however, would, when approached by a customer, say they had an equivalent compound which was not subject to purchase tax.

Mr. Huxon said that his constituents bought their medicine at the local grocer's. The Pharmacy and Medicines Board provided that if a medicine was sold at a value of less than one shilling it could be sold at a value of less than one shilling.

Mr. TURTON said that his constituents bought their medicines at the local grocer's. The Pharmacy and Medicines Acts, 1941, provided that if a medicine was sold without a proprietary designation it could be sold only by a qualified pharmaceutical chemist. The present Bill would ensure that country people who had to go to a grocer would pay 33½% on all their medicine and would not be able to ask for petroleum jelly in place of "Vaseline" because the grocers were used by panel doctors to sell it. Many branded medicines were used by panel doctors, that Dr. BENNET STROSS said Mr. Turton was mistaken in saying there were proper equivalents. A grave view would be taken if a doctor were to prescribe "aspro" instead of aspirin. Mr. TURTON said the dispensing chemist for the district in the past used certain branded products for which the formula under the B.P.C. was taken. Mr. LINSBARD explained that the B.P.C. was a standard quality which he could not alter. He said that the formula under the B.P.C. was a standard quality which he could not alter. He said that the formula under the B.P.C. was a standard quality which he could not alter.

Mr. LINSLEY explained that he was secretary of the Pharmaceutical Society. He pointed out that the Bill did not attempt to amend the Pharmacy and Medicines Act, 1941, which had been an unsatisfactory and long-standing difference between chemists and grocers about the sale of medicines. There was nothing in the 1941 Act or in these proposals which prevented a grocer from selling a branded proprietary article. If a non-branded product contained a recommendation for use the grocer, under the Act of 1941, could not sell it. However the grocer was approached the House came back to the fact that a purchase tax on drugs and machines was taxation on sickness. In his No. 1 Order the Chancellor of the Exchequer had exempted a number of important drugs used in medicine, and in the Eighth Schedule of the present Bill he attempted exemption by class. In the line between taxed and tax-free medicines. In the Bill on the basis of trade mark. A large number of articles which were not advertised normally sold only on the basis of the proprietary name. The Bill would be taken

...basis of taxed and tax-free medicines had been normally sold only on medical prescription would purchase tax. He did not believe it was beyond the wit-
nesses' proposals of the Bill and would have to be mark, designated the whole of the products of a manufac-
turer, designated the whole of the products of a manufac- then those products might be tax-free. Under the old Medicine
Stamp Acts, if a medicine bore a clear indication that it was supplied for dispensing purposes only, that indication rendered the article tax free.

Mr. SWINAKO said some sections of the pharmaceutical pro-
fession suggested that all medicinal proprietaries should be
allowed to advertise in some Continental countries. Under this
system the only medicinal proprietaries on which purchase tax
would be payable would be those advertised exclusively in
the medical and medical journals. The practice of relying
on a trade mark to cure one's ills without reference to a doctor
should be encouraged.

Remuneration of General Practitioners

On May 28 Sir ERNEST GRAHAM-LITTLE asked whether Mr. BEVAN knew that general practitioners felt misgiving as to the arrangement made for their remuneration out of a central pool, the amount of which was variable and unpredictable; and whether he would apply to medical practitioners the system of payment in accordance with mutual agreements specifying fixed amounts.

Mr. BEVAN: No misgivings of this kind have come to my notice and the second part of the question is therefore arise.

Proprietary Preparations

Dental Estimates Board

Sir ERNEST GRAHAM-LITTLE also asked Mr. Bevan on May 28 to name the chairman and members of the Dental Estimates Board; and state what remuneration they would receive.

Mr. BEVAN gave the following information: Chairman, W. L. Boness, L.D.S., R.C.S., remuneration: £1,900 a year. Dental members (whole-time), Mr. V. W. Humpherson, L.D.S., £1,650 a year; Mr. T. Leaver, £1,650 a year; Wing Commander A. P. McClare, L.D.S., R.C.S., £1,650 a year; Mr. F. J. Marson, L.D.S., R.C.S., £1,650 a year. Dental members (part-time), Mr. W. Kelsey Fry, C.B.E., M.C., M.R.C.S., £7 7s. a day; Mr. J. Lauer, L.D.S., R.C.S., £7 7s. a day; Lay members (part-time), Mr. T. Allsop, J.P., £7 7s. a day; Mr. E. W. Spackman, £7 7s. a day.

Reciprocity in Social Insurance.—Reciprocal arrangements have been made between the new schemes of National Insurance and Industrial Injuries Insurance in Great Britain and the corresponding schemes in Northern Ireland, France, and the Isle of Man, and there have been preliminary discussions with Canada, Australia, New Zealand, and other Commonwealth countries. Mr. James Griffiths hopes shortly to carry these discussions further and also to approach the Governments of some other countries with which a basis for reciprocity in social insurance may be found.

No. 21

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended May 22.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (Administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland. Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland. A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales, London (administrative county), will no longer be published.

‡ Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

§ Deaths from poliomyelitis and poliomyelitis for England and Wales are combined.

|| Deaths from poliomyelitis for Wales and Eire.

EPIDEMIOLOGICAL NOTES

Food-poisoning in Perthshire

An outbreak of staphylococcal food-poisoning occurred on May 22 and 23, in Blairgowrie, Perthshire. In the forenoon of May 22, 90 trifles were made and sold; the first few to be sold were eaten at the midday meal. Symptoms began to appear anything from half an hour to 7 hours (in one case 15 hours) after the trifles had been eaten, the average time for a series of 64 cases investigated being 4½ hours. There was copious vomiting followed closely by uncontrollable diarrhoea and agonizing abdominal pain. In the more severe cases this continued for upwards of two hours, by which time the patients were completely collapsed and prostrated. The symptoms stopped as suddenly as they began, recovery being gradual over the next twenty-four hours. With the assistance of the firm's employees as many as possible of the trifles sold were traced. Several samples were obtained, and in all of them *Staphylococcus aureus*, the only pathogen present, was abundantly demonstrated. The sponge-filling was the vehicle of infection and not the cream, to which suspicion had been attached at an early stage of the investigation.

Discussion of Table

In England and Wales a decrease was recorded in the notifications of whooping-cough 437, scarlet fever 321, and measles 202. There were small rises in the incidence of acute pneumonia 17, diphtheria 15, and cerebrospinal fever 12.

A decrease in the incidence of scarlet fever occurred throughout the country except in the south-western counties, where the incidence was unchanged, and in Durham, where there was an increase of 20; the largest decreases were Yorkshire West Riding 58, Lancashire 44, and Staffordshire 31.

For the third consecutive week an increase has been recorded in the notifications of diphtheria; the largest rise during the week under review was 10 in London. The local trends of measles showed considerable fluctuations. The largest decreases were Warwickshire 184, Surrey 159, Lancashire 127, Suffolk 124, and Middlesex 93. The largest increases were Kent 133, Yorkshire West Riding 109, Staffordshire 73, and Gloucestershire 71. A fall in the incidence of whooping-cough was fairly general throughout the country, the largest decreases were Warwickshire 56 and Middlesex 52.

An outbreak of dysentery affecting 9 persons was notified in Glamorganshire, Swansea C.B. The other large returns of dysentery were Lancashire 33 (Lancaster M.B. 13); London 32 (St. Pancras 15); and Yorkshire West Riding 22 (Sheffield C.B. 17). An outbreak of acute poliomyelitis involving 4 persons was notified in Merionethshire, Deudraeth R.D. The only other counties with more than one case of poliomyelitis were Yorkshire West Riding 3, Lancashire 2, and London 2.

In Scotland a small decrease was recorded in the incidence of infectious diseases; the only exception was a rise of 49 in the notifications of measles. The decreases included scarlet fever 27, dysentery 19, acute primary pneumonia 18, and diphtheria 12. In Glasgow there were 13 fewer cases of dysentery and 21 of scarlet fever than in the preceding week.

In Eire decreases were reported in the incidence of measles 28, whooping-cough 23, and scarlet fever 10, with an increase of 17 in the notifications of primary pneumonia. A further 20 cases of measles were notified from the outbreak in Wexford, Wexford U.D. An outbreak of whooping-cough affecting 16 persons was reported from Waterford, Carrick-on-Suir No. 2 R.D.

In Northern Ireland a decrease of 19 was recorded in the notifications of scarlet fever and an increase of 9 for measles.

Week Ending May 29

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,216, whooping-cough 3,083, diphtheria 151, measles 13,468, acute pneumonia 579, cerebrospinal fever 40, acute poliomyelitis 20, dysentery 122, paratyphoid 5, and typhoid 9.

Dr. Mahmoud Erfan Bey, Professor of Medicine at Foad I University, Cairo, is in Britain under the auspices of the British Council in order to meet British authorities on tropical diseases. Dr. Erfan returns to Egypt on June 18.

SOCIETIES AND LECTURES

Monday

EDINBURGH UNIVERSITY: PHYSIOLOGY CLASSROOM.—June 14, 5 p.m.
"Evolution of Medical Education in Scotland," by Dr. Douglas Guthrie.

MEDICAL SOCIETY OF LONDON, 11, Chandos Street, Cavendish Square.
London, W.—June 14, 8 p.m. *Clinical meeting.*

Tuesday

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square,
London, W.C.—June 15, 5 p.m. "*Diseases of the Nails*," by
Dr. H. Corsi.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—At Royal Society of Medicine, 1, Wimpole Street, London, W., June 15, 8.30 p.m.
Cavendish Lecture: "*The Atom and its Energy*," by Prof. E. N. da C. Andrade, F.R.S., D.Sc., Ph.D.

Thursday

ROYAL SOCIETY, Burlington House, Piccadilly, London, W., June 17,
2.30 p.m. Discussion: "Analogue of Growth Factors in Relation
to Antibiotics." To be opened by Sir Paul Fildes, M.B.
B.Ch., F.R.S.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE—At 26, Portland Place, London, W., June 17, 7.30 p.m. Annual general meeting. Presentation of the Chalmers Medals for 1941, 1943, and 1945. 8.15 p.m. "Pulmonary Bilharziasis," by Prof. M. Erfan (Cairo):

Saturday

LONDON ASSOCIATION OF THE MEDICAL WOMEN'S FEDERATION.—A
West Middlesex County Hospital, Isleworth, June 19, 3 p.m.
Clinical meeting.

APPOINTMENTS

STOKE-ON-TRENT NORTH STAFFORDSHIRE ROYAL INFIRMARY—Honorary
Consulting Physician, A. Watts, GL MD FRCP Honorary Lecturer
Ophthalmic Surgeon, T. Aubrey, FRCS FRCP DO H—Honorary Lecturer
Gynaecologist, J. L. Jones, FRCS B.S. MD GA FRCPE
Dermatologist, C. H. Catlin, MD MRCP D.A. FRCPE
Dental Physician, C. H. Catlin, MD MRCP D.A. FRCPE
D. C. Thursty, Pelham, MRCP DCH FRCPE FRCR—P. J. M.
Kent, M.R.C.S., L.R.C.P., D.O.M.S.—D. M. J. E. N. D. 723
M.D., M.R.C.P.Ed., D.P.H.

BIRTHS, MARRIAGES, AND DEATHS

Brounthon.—On May 30, 1944, wife of David H. Brounthon.
Hamilton.—On May 27, 1944, to Menna Lee Lloyd, Mt. Sheldon.—On May 27, 1944 (see Stott), wife of Dr. J. Zinovieff.—On May 21, 1944, Zinovieff, a daughter.

Goulden-Macrae.—On Apr. 22, 1903, at the
Gardens, Edinburgh. Caretaker, Fionna Macrae, Q.
Macrae and the late Mrs. Macrae.

Bailey.—On May 27, 1948

Dougal.—On June 4, 1948, at the
Infirmary, Daniel Dougal,
Obstetrics and Gynaecology

Dunlop.—On May 31, 1948, Dunlop was transferred to the M.O.H. for Torquay.

Inness.—On May 30, 1944 at
William James Deacon 1st
West African Medical Stat.

Mooney, M.B., BCh FRCS
Oxford—On May 30 1942

Boyle Hill Scott, M B

Smith.—On May 26, 1925, Walter Sikes, M.D. D.S. 1925, 1926, 1927, 1928, 1929, 1930, 1931, 1932, 1933, 1934, 1935, 1936, 1937, 1938, 1939, 1940, 1941, 1942, 1943, 1944, 1945, 1946, 1947, 1948, 1949, 1950, 1951, 1952, 1953, 1954, 1955, 1956, 1957, 1958, 1959, 1960, 1961, 1962, 1963, 1964, 1965, 1966, 1967, 1968, 1969, 1970, 1971, 1972, 1973, 1974, 1975, 1976, 1977, 1978, 1979, 1980, 1981, 1982, 1983, 1984, 1985, 1986, 1987, 1988, 1989, 1990, 1991, 1992, 1993, 1994, 1995, 1996, 1997, 1998, 1999, 2000, 2001, 2002, 2003, 2004, 2005, 2006, 2007, 2008, 2009, 2010, 2011, 2012, 2013, 2014, 2015, 2016, 2017, 2018, 2019, 2020, 2021, 2022, 2023, 2024, 2025, 2026, 2027, 2028, 2029, 2030, 2031, 2032, 2033, 2034, 2035, 2036, 2037, 2038, 2039, 2040, 2041, 2042, 2043, 2044, 2045, 2046, 2047, 2048, 2049, 2050, 2051, 2052, 2053, 2054, 2055, 2056, 2057, 2058, 2059, 2060, 2061, 2062, 2063, 2064, 2065, 2066, 2067, 2068, 2069, 2070, 2071, 2072, 2073, 2074, 2075, 2076, 2077, 2078, 2079, 2080, 2081, 2082, 2083, 2084, 2085, 2086, 2087, 2088, 2089, 2090, 2091, 2092, 2093, 2094, 2095, 2096, 2097, 2098, 2099, 2100, 2101, 2102, 2103, 2104, 2105, 2106, 2107, 2108, 2109, 2110, 2111, 2112, 2113, 2114, 2115, 2116, 2117, 2118, 2119, 2120, 2121, 2122, 2123, 2124, 2125, 2126, 2127, 2128, 2129, 2130, 2131, 2132, 2133, 2134, 2135, 2136, 2137, 2138, 2139, 2140, 2141, 2142, 2143, 2144, 2145, 2146, 2147, 2148, 2149, 2150, 2151, 2152, 2153, 2154, 2155, 2156, 2157, 2158, 2159, 2160, 2161, 2162, 2163, 2164, 2165, 2166, 2167, 2168, 2169, 2170, 2171, 2172, 2173, 2174, 2175, 2176, 2177, 2178, 2179, 2180, 2181, 2182, 2183, 2184, 2185, 2186, 2187, 2188, 2189, 2190, 2191, 2192, 2193, 2194, 2195, 2196, 2197, 2198, 2199, 2200, 2201, 2202, 2203, 2204, 2205, 2206, 2207, 2208, 2209, 2210, 2211, 2212, 2213, 2214, 2215, 2216, 2217, 2218, 2219, 2220, 2221, 2222, 2223, 2224, 2225, 2226, 2227, 2228, 2229, 2230, 2231, 2232, 2233, 2234, 2235, 2236, 2237, 2238, 2239, 2240, 2241, 2242, 2243, 2244, 2245, 2246, 2247, 2248, 2249, 2250, 2251, 2252, 2253, 2254, 2255, 2256, 2257, 2258, 2259, 2260, 2261, 2262, 2263, 2264, 2265, 2266, 2267, 2268, 2269, 2270, 2271, 2272, 2273, 2274, 2275, 2276, 2277, 2278, 2279, 2280, 2281, 2282, 2283, 2284, 2285, 2286, 2287, 2288, 2289, 2290, 2291, 2292, 2293, 2294, 2295, 2296, 2297, 2298, 2299, 2300, 2301, 2302, 2303, 2304, 2305, 2306, 2307, 2308, 2309, 2310, 2311, 2312, 2313, 2314, 2315, 2316, 2317, 2318, 2319, 2320, 2321, 2322, 2323, 2324, 2325, 2326, 2327, 2328, 2329, 2330, 2331, 2332, 2333, 2334, 2335, 2336, 2337, 2338, 2339, 2340, 2341, 2342, 2343, 2344, 2345, 2346, 2347, 2348, 2349, 2350, 2351, 2352, 2353, 2354, 2355, 2356, 2357, 2358, 2359, 2360, 2361, 2362, 2363, 2364, 2365, 2366, 2367, 2368, 2369, 2370, 2371, 2372, 2373, 2374, 2375, 2376, 2377, 2378, 2379, 2380, 2381, 2382, 2383, 2384, 2385, 2386, 2387, 2388, 2389, 2390, 2391, 2392, 2393, 2394, 2395, 2396, 2397, 2398, 2399, 2400, 2401, 2402, 2403, 2404, 2405, 2406, 2407, 2408, 2409, 2410, 2411, 2412, 2413, 2414, 2415, 2416, 2417, 2418, 2419, 2420, 2421, 2422, 2423, 2424, 2425, 2426, 2427, 2428, 2429, 2430, 2431, 2432, 2433, 2434, 2435, 2436, 2437, 2438, 2439, 2440, 2441, 2442, 2443, 2444, 2445, 2446, 2447, 2448, 2449, 2450, 2451, 2452, 2453, 2454, 2455, 2456, 2457, 2458, 2459, 2460, 2461, 2462, 2463, 2464, 2465, 2466, 2467, 2468, 2469, 2470, 2471, 2472, 2473, 2474, 2475, 2476, 2477, 2478, 2479, 2480, 2481, 2482, 2483, 2484, 2485, 2486, 2487, 2488, 2489, 2490, 2491, 2492, 2493, 2494, 2495, 2496, 2497, 2498, 2499, 2500, 2501, 2502, 2503, 2504, 2505, 2506, 2507, 2508, 2509, 2510, 2511, 2512, 2513, 2514, 2515, 2516, 2517, 2518, 2519, 2520, 2521, 2522, 2523, 2524, 2525, 2526, 2527, 2528, 2529, 2530, 2531, 2532, 2533, 2534, 2535, 2536, 2537, 2538, 2539, 2540, 2541, 2542, 2543, 2544, 2545, 2546, 2547, 2548, 2549, 2550, 2551, 2552, 2553, 2554, 2555, 2556, 2557, 2558, 2559, 2560, 2561, 2562, 2563, 2564, 2565, 2566, 2567, 2568, 2569, 2570, 2571, 2572, 2573, 2574, 2575, 2576, 2577, 2578, 2579, 2580, 2581, 2582, 2583, 2584, 2585, 2586, 2587, 2588, 2589, 2590, 2591, 2592, 2593, 2594, 2595, 2596, 2597, 2598, 2599, 2600, 2601, 2602, 2

Wilson.—On May 20, 1944, taken, Bishop Auckland, Dou-

Edward Wilson, M.D. Aberd

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions which should be typed. We publish here a selection of these questions and answers which seem to be of general interest.

Care of Teeth in Children

Q.—I find that dentists frequently recommend parents to bring their young children aged 3-4 years to them to have the cavities of their temporary teeth filled. I do so, I am told, in order to prevent decay starting in the permanent teeth when these come. Is this advisable, and is there an excellent foundation for doing so?

A.—It is most important that children should have adequate conservative dental treatment to their temporary teeth. This is not for the reason given, but to prevent crowding of the permanent teeth due to early loss of the deciduous molars, which is the commonest cause. The first eruption of the permanent series is erupts the first molars, which erupt behind the deciduous ones. The next permanent teeth are the incisors in front which replace the deciduous incisors. If the temporary molars have been lost owing to decay the permanent teeth move in to fill the gap. There is no room left then for the canines and premolars, which erupt later and tend into proper alignment.

Corrected Sedimentation Rate in Anaemia

Q.—What is the effect on the rate of interest if the rate is raised?
 A.—The rate of interest is raised, and the rate of interest is raised.
 Q.—What is the effect on the rate of interest if the rate is raised?
 A.—The rate of interest is raised, and the rate of interest is raised.
 Q.—What is the effect on the rate of interest if the rate is raised?
 A.—The rate of interest is raised, and the rate of interest is raised.

4. - The relationship between sedimentation rate and erythrocyte concentration is not a linear one, and any simple calculation will be "correct" for anaemia. One who is "correct" in clinical terms, because the "correction" makes certain values normal, is not entirely right. Nevertheless, Winthby's *Clinical Haematology* (2nd ed. p. 322) finds that in practice the corrected figure is "usually" informative. The most convenient formula to use is the one printed in Winthby and Burtin's *Directions in the Blood* (4th edition, p. 606), from which, for a given haematocrit and sedimentation rate one can read off the corrected sedimentation rate and discover whether it is definitely increased, slightly increased, and so on. This introduces the right note of caution into the result and discourages the laying of too much stress on small differences.

Treatment of Paget's Disease of Bone

Q.—Is there any recent treatment?—Purser's disease of bone?
A.—The patient of mine, aged 60 has it in one femur, which
is greatly bowed. The diagnosis has been confirmed
radiologically.

A.—The answer must unfortunately be "No." There is no new treatment of proved value in relieving the symptoms of this disease. Many workers have claimed that Paget's disease is one manifestation of hyperparathyroidism; and Hefelt (*Brit. J. Surg.*, 1939-40 27, 651) has further suggested that the hyperparathyroidism may be secondary to a retention of phosphates in the body. On this assumption he has advised treatment by small doses of aluminium acetate, which inhibits the absorption of phosphates from the intestine by combining with them to form insoluble aluminium phosphate, which is excreted unchanged from the bowel. The theory underlying this form of treatment has not been proved, and, although promising results were claimed in a few patients, much further confirmation is required before the method could become widely accepted. Meanwhile some of the older forms of treatment are still in use, including "guttering" of the bone, deep x-ray therapy, and occasionally osteotomy. There is a tendency, however, to advise against any active treatment, particularly when the symptoms are not severe, in view of the uncertainty of the results, and because of the rare but definite complication

of carcinoma following injury in these cases. See also the answer to a question on calcium metabolism in Paget's disease in our issue of Jan. 24 (p. 183).

Keeping Qualities of Glucose-saline

Q.—What are the keeping properties of 5% and 20% glucose in normal saline? This is made up with pyrogen-free water and kept in a sealed bottle of alkali-free glass after the usual non-sterilizing sterilization.

A.—A solution containing these ingredients made up as described should keep, one might almost say, indefinitely, provided the sterilization has been carried out in the final containers, previously sealed; the closure must be perfect at the end of the process and remain so during storage. There is a requirement in the first Addendum to the *British Pharmacopoeia*, 1932, for sterilized water and physiological solution of sodium chloride, that if the closure is made with non-absorbent cotton-wool wrapped in gauze the contents are to be used within one month after preparation, but if kept in a container which is sealed by fusion of the glass or by some equally effective method they may be stored for "a longer period". The same remarks could equally well be applied to solutions of glucose in normal saline.

Comparison of Mortality Rates

Q.—What are the mortality rates of the following diseases in the United Kingdom for 1925-7 and 1945-7: puerperal sepsis, heart disease, pneumonia, tuberculosis, cancer, Bright's disease, diabetes and pernicious anaemia?

A.—A comparison of the number of deaths from puerperal sepsis over the last twenty years cannot be made because the individual causes included under this heading were revised in 1940, it is not possible to reconstruct the group from the sub-groups. Bright's disease was not tabulated separately but was included under the heading of nephritis.

In 1940 a change was made in the method of tabulating causes of death. Previously a rule of preference had been established when two or more causes of death were mentioned on the death certificate, but from 1940 the physician's preference was noted. This made a considerable difference to the number of deaths assigned to some causes. Factors have been found that make a correction for this change of classification, and we must be able to get any comparison. The following rates are of use.

Crude Death Rates per 1,000,000 in England and Wales

	1925	1926	1927	1945	Ratio for Conversion
Puerperal sepsis	1,647	1,651	1,835	1,354	0.994
Heart disease	951	828	948	521	1.040
Pneumonia	1,039	961	972	615	0.974
Tuberculosis	933	771	791	515	0.969
Cancer	1,098	1,430	1,443	1,990	0.971
Bright's disease	221	326	353	327	1.128
Diabetes	112	115	126	106	0.689
Pernicious anaemia	66	71	68	55	0.757

The ratio for conversion is the value by which the pre-1940 rate must be multiplied to make them comparable with the modern rates.

Male Infertility

Q.—Where a fresh specimen of semen contains apparently normal numbers of spermatozoa, but completely non-motile, can any useful treatment be given?

A.—It is the prognosis and treatment (if any) in a case of male infertility in which examination of semen (condom-squeezed) gave the following results: February, 1947: 24 million spermatozoa per ml.; motility nil; abnormal forms 25%. November, 1947: 12.5 million spermatozoa per ml.; motility nil; abnormal forms 40%. The general health is good, there is no genital abnormality. Is one justified in recommending treatment? It should be told that treatment is

of no value. It is necessary to know how the specimen of semen was obtained. Many cases of non-motility of the spermatozoa are due to the fact that the semen was collected in a container which was not repeatedly washed, are

likely to contain traces of chemicals used in their manufacture. Necrozoospermia is very rare and is almost always associated with other defects in the semen, reduction in numbers, high percentage of abnormal forms, etc. It would be advisable to have another specimen examined and to arrange for a more complete analysis.

(b) Prognosis and treatment are always difficult when one is ignorant of the aetiology of a disease, and as yet we have very little knowledge of the factors responsible for subfertility. The absence of any motility in the sperms may be partly explained by the use of a condom for the collection of the specimen. It is likely, however, that motility and viability were both reduced. In this case, therefore, we are dealing with oligozoospermia, reduced motility and viability, and an increased incidence of abnormal forms, especially in the second specimen. Should the patient's wife conceive she would probably have a miscarriage. It would be a mistake to tell the patient that there is no hope, for fertility fluctuates in such cases and spontaneous improvement frequently occurs. A search should be made for a focus of infection anywhere in the body, and if found this should be treated. He might also be given very large doses of vitamin E and a course of some anterior-pituitary-like hormone. A more accurate prognosis could be given if a testicular biopsy were carried out.

NOTES AND COMMENTS

Tecira Tummy.—Dr. G. BROADBENT LIBBEY (Newcastle-upon-Tyne) writes: Can anybody who was stationed in the Azores during the war give any information on "Tecira tummy"—its clinical course, diagnosis, bacteriological findings, and treatment? A young airman suffered from this in 1944; from his history the condition was not adequately investigated and treated. A few weeks ago he presented himself with a history of continued diarrhoea with loss of weight and energy; the only significant finding clinically being the typical rope-like, slightly tender, pelvic colon of chronic dysentery. Stools on culture have grown *B. dysenteriae* Sonne which persists after 40 g. of sulphaguanidine. It would appear that the two are related.

Legal Ownership of X-ray Films.—Dr. HELEN W. RUSK (Southport) writes: I was interested in your views on the legal ownership of x-ray films ("Any Questions?" May 29, p. 1059). When I was x-rayed in Prof. Schaul's department before departing as a *Janita* into one of Berlin's greatest tuberculosis sanatoria, I was given the film without asking for it. When films are kept by the radiologist, who can stop him from destroying them under the label "lost" or "cannot be found," etc., whenever he is accused of negligence? As long as the films can be produced when required the radiologist will always be able to defend himself, no matter who owns them. Whenever the patient has difficulty in getting his films, there is always a reason for it.

Corrections

The date of the death of Dr. Peter Frankel was by error given as April 16 (*Journal*, June 5, p. 1113). This should have been April 10.

In the legends to the photomicrographs illustrating the paper by Dr. G. Harvey Smith (June 5, p. 1078) the magnifications of the two sections shown were omitted. Fig. 1 was $\times 260$ and Fig. 2 $\times 120$.

Dr. J. COUTTS MILNE (Singapore) writes: Possibly some reader or statistician has already drawn your attention to what appears to me to be an error in the annotation headed "Poliomyelitis" in the *Journal* of March 27 (p. 608) in which Bradley and Gale's survey of poliomyelitis in England is reviewed. The attack rate should, I think, read 18 per 100,000 in place of 3.8 per 100,000. The latter rate is that for 1938, the year of previously highest recorded incidence.

[The figure given by Dr. Coutts Milne is correct, and we are obliged to him for pointing out the error.—Ed., *B.M.J.*]

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY JUNE 12 1948

British Medical Association

ONE HUNDRED AND SIXTEENTH ANNUAL MEETING, CAMBRIDGE.
JUNE 25 TO JULY 2, 1948

President-Elect · SIR LIONEL WHITBY, C.V.O., M.C., M.A., M.D., F.R.C.P., Regius Professor of Physic,
University of Cambridge; Master of Downing College, Cambridge

PROGRAMME

SCIENTIFIC SECTIONS

The following Sections will meet on Three Days:

MEDICINE

President: L. B. COLE, M.D., F.R.C.P. (Cambridge)
Vice-Presidents: BRANFORD MORGAN, M.D., F.R.C.P. (Norwich); WILLIAM EVANS, M.D., D.Sc., F.R.C.P. (London); Prof. JOHN McMICHAEL, F.R.S. Ed., M.D., F.R.C.P. Ed. (London); R. BODLEY SCOTT, D.M., F.R.C.P. (London).
Hon. Secretaries: L. C. MARTIN, M.D., F.R.C.P., Campden, Trumpington Road, Cambridge; K. M. A. PERRY, M.D., F.R.C.P., London Hospital, E.I.

Official Reporter: Dr. K. M. A. PERRY.

Meeting-place: Zoology Dept., entrance Pembroke Street

Wednesday, June 30—10 a.m. *Discussion*: Thiouracil in the Treatment of Thyrotoxicosis. To be opened by Prof. H. P. HEMS WORTH (London), followed by Mr. C. DONALD (London), Dr. D. VEREL (Aberdeen), Dr. H. COOKSON (Bournemouth), Dr. L. W. HALE (Cambridge), and Dr. RUSSELL FRASER (London). 2.30 p.m., Demonstration of Electro-phonocardiography by Dr. E. D. H. COWEN (Cambridge)

Thursday, July 1 (Combined Meeting with Section of Surgery).—10 a.m., *Discussion*: Surgery in Hypertension. To be opened jointly by Dr. R. H. SMITHWICK (U.S.A.) and Dr. HORACE EVANS (London), followed by Mr. D. W. C. NORTHFIELD (London), Dr. A. R. GILCHRIST (Aberdeen), and Mr. F. F. STOCK (Liverpool). 2.30 p.m. The Value of Sound-films in Medical Teaching; Illustrated by a Film on Peptic Ulceration (by courtesy of Messrs. John Wyeth and Brother Limited)

Friday, July 2—10 a.m. A communication from Prof. GEORGE R. MINOT (Harvard, U.S.A.) on "Permeious Anaemia" will be read by Sir Lionel Whitby before his Opening Paper. *Discussion*: The Modern Management of Macrocytic Anaemias. To be opened by Sir LIONEL WHITBY (Cambridge), followed by Dr. J. F. WILKINSON (Manchester), Dr. C. C. UNGLEY (Newcastle-upon-Tyne), and Dr. R. R. BOMFORD (London).

SURGERY

President: VERNON C. PENNELL, F.R.C.S. (Cambridge).
Vice-Presidents: P. H. R. GREY, M.Ch., F.R.C.S. (Cambridge); A. M. A. MOORE, F.R.C.S. (London); Prof. IAN AIRD, Ch.M., F.R.C.S. (London)

Hon. Secretaries: B. MCN. TRUSCOTT, F.R.C.S., 1, Shaftesbury Road, Brooklands Avenue, Cambridge; R. SAMPSON HANDLEY, O.B.E., F.R.C.S., 55, Harley Street, W.1.

Official Reporter: Prof. IAN AIRD

Wednesday, June 30. *Meeting-place*: Botany Dept., entrance Tennis Court Road.—10 a.m. *Discussion*: Tuberculous Adenitis. To be opened by Mr. DENIS BROWNE (London),

followed by Mr. HUGH REID (Liverpool) and Mr. ROWLAND REID (Colchester).

Thursday, July 1. *Meeting-place*: Zoology Dept., entrance Pembroke Street (Combined Meeting with Section of Medicine).—10 a.m., *Discussion*: Surgery in Hypertension. To be opened jointly by Dr. R. H. SMITHWICK (U.S.A.) and Dr. HORACE EVANS (London), followed by Mr. D. W. C. NORTHFIELD (London), Dr. A. R. GILCHRIST (Aberdeen), and Mr. F. F. STOCK (Liverpool). 2.30 p.m., The Value of Sound-films in Medical Teaching; Illustrated by a Film on Peptic Ulceration (by courtesy of Messrs. John Wyeth and Brother Limited).

Friday, July 2. *Meeting-place*: Botany Dept., entrance Tennis Court Road.—10 a.m., *Discussion*: Carcinoma of the Breast. To be opened by Sir CECIL WAKELEY (London), followed by Dr. FRANK ELLIS (London), Mr. J. B. OLDHAM (Liverpool), and Mr. R. L. HOLT (Manchester).

OBSTETRICS AND GYNAECOLOGY

President: J. R. CAMPBELL CANNEY, M.D., F.R.C.O.G. (Cambridge).

Vice-Presidents: F. R. STANSFIELD, M.D., F.R.C.S., F.R.C.O.G. (Ipswich); Prof. HILDA N. LLOYD, F.R.C.S., F.R.C.O.G. (Birmingham); DONALD McINTYRE, M.B.E., F.R.S. Ed., M.D., F.R.C.S. Ed., F.R.F.P.S., F.R.C.O.G. (Glasgow).

Hon. Secretaries: O. LLOYD, M.D., F.R.C.S., M.R.C.O.G., 34, Lensfield Road, Cambridge; J. H. PEEL, F.R.C.S., F.R.C.O.G., 86, Harley Street, W.1.

Official Reporter: Dr. G. G. LENNON.

Meeting-place: Organic Chemistry Dept., entrance Pembroke Street.

Wednesday, June 30—10 a.m., *Discussion*: The Problem of Infertility and its Treatment. To be opened by Dr. BETHEL SOLOMONS (Dublin), followed by Mr. ALBERT SHARMAN (Glasgow), Mr. KENNETH WALKER (London), Mr. PERCY MALPAS (Liverpool), and Mr. CECIL BINNEY (Barrister-at-Law, The Temple).

Thursday, July 1 (Combined Meeting with Section of Anaesthetics).—10 a.m., *Discussion*: Analgesia in Midwifery. To be opened by Prof. W. C. NIXON (London), followed by Dr. P. J. HELLWELL (London) and Dr. A. M. HUTTON (London). 2.30 p.m., (1) Film from Dept. of Anaesthetics at Liverpool on Anaesthesia for Caesarean Section (in Mineralogy Dept., Downing Street); (2) Demonstration of Apparatus.

Friday, July 2—10 a.m., *Discussion*: The Management of the Third Stage of Labour and its Complications. To be opened by Dr. T. FLEW (London), followed by Prof. H. L. SREEHAN (Liverpool) and Dr. P. MOLLISON (London). 2.30 p.m., Films (in Zoology Lecture Theatre, entrance Pembroke Street): (1) Trichomonas Vaginitis; (2) Eclampsia.

The following Sections will meet on Two Days:

ANAESTHETICS

President: Z. MENNELL, M.B., D.A. (Petworth).

Vice-Presidents: C. H. BUDD, M.B., B.Ch., D.A. (Cambridge); W. ALEXANDER LOW, M.C., M.B., B.S., D.A. (London); T. C. GRAY, M.B., Ch.B., D.A. (Liverpool).

Hon. Secretaries: RONALD JARMAN, D.Sc., M.R.C.S., L.R.C.P., D.A., 36, Queen Anne Street, London, W.1; H. R. YOUNGMAN, M.D., D.A., 1, Huntingdon Road, Cambridge.

Official Reporter: Dr. T. C. GRAY.

Wednesday, June 30. Meeting-place: Mineralogy Dept., entrance Downing Street.—10 a.m., *Discussion:* Anaesthesia for Chest Operations. To be opened by Dr. JOAN MILLAR (Newcastle), followed by Dr. E. H. RINK (London). 2.30 p.m., *Occasional Papers:* (1) Abdominal Relaxation, by Dr. C. B. LEVINS (London); (2) The Uses of Caudal Extradural Block, by Dr. G. C. STEEL (London); (3) When to Intubate in Babies and Children, by Dr. ROBERT COPE (London).

Thursday, July 1.—10 a.m. (Combined Meeting with Section of Obstetrics and Gynaecology in the Organic Chemistry Dept., entrance Pembroke Street). *Discussion:* Analgesia in Midwifery. To be opened by Prof. W. C. NIXON (London), followed by Dr. P. J. HELLIWELL (London) and Dr. A. M. HUTTON (London). 2.30 p.m., *Films* (in Mineralogy Dept., Downing Street): (1) Anaesthesia for Caesarean Section (Dept. of Anaesthesia, University of Liverpool); (2) Caudal Analgesia (H. Lilly and Co.); (3) Shock (I.C.I.); (4) Respiratory and Cardiac Arrest (I.C.I.).

CHILD HEALTH

President: Prof. Sir LEONARD PARSONS, M.D., F.R.C.P., F.R.C.O.G. (Birmingham).

Vice-Presidents: Prof. R. W. B. ELLIS, O.B.E., M.D., F.R.C.P. (Edinburgh); JLAN M. MACKINTOSH, M.D., D.P.H. (Birmingham); Prof. N. B. CAPON, M.D., F.R.C.P. (Liverpool).

Hon. Secretaries: JANET D. ROSCOR, M.B., B.S., D.C.H., 4, Millington Road, Cambridge; R. M. MAYON-WHITE, M.B., B.S., Department of Experimental Medicine, University of Cambridge.

Official Reporter: Prof. W. S. CRAIG.

Meeting-place: Agriculture Dept., entrance Tennis Court Road or Downing Street.

Thursday, July 1.—10 a.m. *Discussion:* Neonatal Mortality and Morbidity. To be opened by Dr. AGNES R. MACGREGOR (Edinburgh), followed by Prof. L. S. PENROSE (London), Congenital Abnormalities and Genetic Factors Contributing to Neonatal Mortality and Morbidity; Dr. WINIFRED YOUNG (Liverpool) Some Physiological Handicaps of the Premature Infant; Prof. N. B. CAPON (Liverpool), Obstetrical Factors Contributing to Neonatal Mortality; Dr. J. L. HENDERSON (Edinburgh), Infection.

Friday, July 2 (Combined Meeting with Section of Radiology). 10 a.m. *Discussion:* Malignant Disease in Infancy and Childhood. To be opened by Prof. WILFRID GAISFORD (Manchester), followed by Dr. C. G. TALL (Birmingham), The Radiological Diagnosis of Malignant Disease in Children; Prof. J. S. MITCHELL (Cambridge), Radiotherapy of Malignant Disease in Childhood; Dr. A. M. BARRETT (Cambridge), The Pathology of Malignant Disease in Childhood. 2.30 p.m., *Demonstrations:* Work in Progress on the Weights of Normal Newborn in the First Ten Days of Life, by Dr. JANET D. ROSCOR (Cambridge) at County Maternity Unit, Mill Road.

DISEASES OF THE CHEST

President: F. R. LEAR, M.C., M.D., F.R.C.P. (London).

Vice-Presidents: W. PATER PHILIP, M.B., Ch.B., D.M.R.E., D.P.H. (London); F. H. YOUNG, O.B.E., M.D., F.R.C.P. (London); F. C. BRUCE, M.S., F.R.C.S. (London).

Hon. Secretaries: I. B. STOTT, J.P., M.C., M.B., Ch.B., D.P.H., 1, Addenbrooke's Village Settlement, Cambridge; A. MAGGAPET, M.D., M.D., F.R.C.P., 41, Devonshire Street, W.1.

Official Reporter: Mr. P. C. BRUCE.

Meeting-place: Agriculture Dept., entrance Tennis Court Road or Downing Street.

Thursday, June 30. Meeting-place: (1) Bronchial Disease, by Mr. P. C. BRUCE (London).

followed by Mr. G. A. MASON (Newcastle-upon-Tyne); Mrs. E. L. G. HILTON (London); (2) Surgery of Congenital Heart Disease. To be opened by Dr. J. M. H. CAMPE (London), followed by Mr. T. HOLMES SELLORS (London). Afternoon: Visit to Papworth.

Thursday, July 1.—10 a.m. *Discussions:* (1) The Relationship between Upper Respiratory Infection and Radiological Appearances in the Lungs. To be opened by Dr. W. PATER PHILIP (Cambridge); (2) The Present-day Treatment of Pneumonia. To be opened by Dr. LINDSEY W. BATTEN (London) (under title "Modern Pneumonia"). Afternoon: (1) Demonstration of x-ray films; (2) Cinema films: (a) Surgery in Chest Disease, (b) The Technique of Artificial Pneumothorax (lent by the British Council).

OCCUPATIONAL HEALTH

President: DONALD STEWART, M.D., F.R.C.P.Ed. (Birmingham).

Vice-Presidents: J. A. L. VAUGHAN JONES, M.B., Ch.B. (Leeds); Prof. R. E. LANE, F.R.C.P. (Manchester); W. E. CHIESMAN, M.D., F.R.C.P. (London).

Hon. Secretaries: C. H. HOSKYN, O.B.E., M.B., B.Chir., Health Department, Austin Motor Co., Ltd., Longbridge, Birmingham; P. PRINGLE, LL.B., M.R.C.S., L.R.C.P., D.I.H., Chief Medical Officer, British Electricity Authority, Great Portland Street, London, W.1; MILLICENT NOURSE, M.R.C.S. L.R.C.P., 1, Grange Road, Cambridge.

Official Reporter: Miss E. A. FAULKNER.

Meeting-place: Physical Chemistry Dept., entrance Fins School Lane.

Thursday, July 1.—10 a.m. *Discussion:* Human Relations in Industry. To be opened by Sir GEORGE SCHUSTER, K.C.S.I., K.C.M.G., C.B.E., M.C. (Chairman, Panel on Human Factors, Cabinet Committee on Industrial Productivity); followed by Dr. ELLIOT JAKES (London), Human Relations and Occupational Health, and Dr. R. F. TREDGOLD (Cambridge) and Mr. JEROME F. SCOTT (Harvard, U.S.A.), Education in Human Relations in Industry. 2.30 p.m., Visits to Papworth Village Settlement and Pye Radio Factory.

Friday, July 2.—10 a.m. *Discussion:* Aviation Medicine. To be opened by Air Marshal Sir HAROLD WHITTINGHAM, K.C.B. (London), Aviation Medicine as Applied to Civil Aviation, followed by Dr. W. K. STEWART, A.F.C. (Farnborough), The Physiology of Stratosphere Flying, and Prof. Sir FREDERICK BARTLETT, F.R.S. (Cambridge), Fatigue in Flying. General discussion to be opened by Air Vice-Marshal P. C. LIVINGSTONE, C.B., C.B.E. (London). 2.30 p.m., Visit to Pye Radio Factory.

OPHTHALMOLOGY

President: O. GAYER MORGAN, M.Ch., F.R.C.S. (London).

Vice-Presidents: E. G. RECORDON, M.D. (Cambridge); O. M. DUTHIE, M.D. (Manchester); J. H. DOGGART, M.D., F.R.C.S. (London).

Hon. Secretaries: G. F. WRIGHT, M.B., B.Chir., D.O.M.S., 22, Parkside, Cambridge; A. G. CROSS, M.D., F.R.C.S., 27, Harley Street, W.1.

Official Reporters: Prof. ARNOLD SORSBY (July 1); Dr. JOHN HAYTHORNE (July 2).

Meeting-place: Geography Dept., entrance Downing Place.

Thursday, July 1.—10 a.m. *Discussion:* Ophthalmic Problems Associated with Gynaecological and Obstetrical Conditions. To be opened by Mr. F. A. JULER (London), followed by Mr. A. B. NUTT (Sheffield). Afternoon, *Occasional Papers:* The Present-day Position of Contact Lenses, by Mr. A. G. CROSS (London); Optical Aids to the Other Man's Job, by Mr. J. G. DRUMMOND CURRIE (Cheltenham); The Heredity of Eye Diseases, by Dr. P. H. BEATTIE (Norwich); Nutritional Eye Diseases, by Dr. H. RYAN (London).

Friday, July 2.—10 a.m. *Discussion:* The Significance and Interpretation of Refraction. To be opened by Mr. E. G. RECORDON (Cambridge), followed by Mr. ARTHUR LISH (London) and Mr. VICTOR PURVIS (London). Afternoon, Clinical Meeting at Addenbrooke's Hospital, Eye Dept. 3 p.m., *Films:* Operations for Detachment by Stallard; Internal and Extracapsular Cataract Extraction; Strabismus and Glaucoma (in Lecture Room, Addenbrooke's).

BENECOL

Benger

Intestinal Extract for the treatment of Rheumatic Diseases

CLINICAL TRIALS OF BEVECOL EXTEND OVER 7 YEARS

Literature and case reports on request. Benger's Ltd., Holmes Chapel, Cheshire

TRADE MARK

'THALAZOLE'

BRAND

phthalylsulphathiazole

the sulphonamide of choice in gastro-intestinal infections

In common with its succinyl analogue, phthalylsulphathiazole is only sparingly absorbed from the gastro-intestinal tract. Its advantages lie in its greater bacteriostatic activity and the retention of this activity to a greater extent in the presence of watery diarrhoeas.

SUPPLIED IN CONTAINERS OF 25, 100
AND 500 TABLETS OF 0.50 GRAMME

THE 'THALAZOLE' BOOKLET IS AVAILABLE ON REQUEST

MANUFACTURED BY
MAY & BAKER LTD.

Painless INTRAMUSCULAR INJECTIONS

e.g. of PENICILLIN, LIVER EXTRACTS,
ARSENO-BENZOLS, BISMUTH, etc.

Many substances create some pain on intramuscular injection. Novutox injected at the same time will prevent this pain.

Most substances are compatible with Novutox, which is also non-destructible to penicillin during the time that the latter is undergoing absorption.

Mixtures with Novutox should be made
immediately before use ONLY

NOVUTOX Self-Sterilising LOCAL ANAESTHETIC

Each c.c. of Novutox 2% contains 0.02 gm. ethocaine hcl., 0.00002 gm. epinephrine and 0.00002 gm. capryl hydrocupreinatoxin hcl. Other strengths of Novutox contain these elements (with or without epinephrine) in varying proportions.

Vitamin Therapy - its uses and limitations

CONGESTIVE FAILURE with oedema

The poor absorption, distribution and utilisation of nutrients resulting from a failing circulation frequently cause deficiencies of the vitamin B complex. These tend to accelerate the development of congestive failure. While vitamins cannot affect valvular disease, they may bring about a reduction of oedema and an improvement in appetite and general well-being. The best preparation for this purpose is

BEFORTISS B-complex

The 4-factor preparation in capsules and ampoules

	capsule	1 c.c. amp.	2 c.c. amp.
aneurine			
hydrochloride	1.0 mg.	10 mg.	50 mg.
riboflavine	1.0 mg.	1 mg.	4 mg.
nicotinamide	15.0 mg.	40 mg.	200 mg.
pyridoxine	0.5 mg.	1 mg.	5 mg.

NYLON MONOFILAMENT *Non-absorbable* SURGICAL SUTURES

'VASANO'

For the prevention and treatment of
TRAVEL SICKNESS

'Vasano' consists of the camphoric acid salts of hyoscine and hyoscyamine. The former is acknowledged to be one of the best single agents for the prevention of air and sea sickness. The balanced combination of alkaloids in 'Vasano' affords both central and peripheral actions. Hyoscine exerts a sedative influence on the higher centres and is also a para-sympathetic depressant while Hyoscyamine acts peripherally inhibiting the vagus.

'VASANO'

is a proven remedy and is effective in all forms of travel sicknesses—sea, air, car or train.

BRITISH SCHERING LIMITED

157-169, Great Portland Street, London, W.1

ORTHOPAEDICS

President: Prof. T. P. McMURRAY, M.Ch., F.R.C.S. (Liverpool).

Vice-Presidents: N. ROSS SMITH, Ch.M., F.R.C.S. (Bournemouth); R. W. BUTLER, M.D., M.Ch., F.R.C.S. (Cambridge); H. A. BRITAIN, O.B.E., M.Ch., F.R.C.S. (Norwich).

Hon. Secretaries: J. F. BOURDILLON, F.R.C.S., Addenbrooke's Hospital, Cambridge; H. H. LANGSTON, F.R.C.S., Gifford House, St. Giles Hill, Winchester.

Official Reporter: Mr. NORMAN CAPENER.

Meeting-place: Anatomy Dept., entrance Tennis Court Road.

Wednesday, June 30.—10 a.m., Discussion: The Clinical Significance and Treatment of Lesions of the Intervertebral Disk. To be opened jointly by Prof. NORMAN M. DOTT, C.B.E. (Edinburgh), and Mr. NORMAN CAPENER (Exeter), followed by Mr. R. H. YOUNG (London). *Occasional Paper:* The Injection Treatment of Osteoarthritis, by Mr. GRANT WAUGH (Sunderland).

Thursday, July 1.—10 a.m., Discussion: The Operative Treatment of Recent Fractures. To be opened by Mr. BRYAN MCFARLAND (Liverpool), followed by Mr. JAMES PATRICK (Glasgow) and Mr. EYRE-BROOK (Bristol). *Occasional Paper:* The Treatment of Osteomyelitis, by Dr. J. TRUETA (Oxford).

PATHOLOGY AND BACTERIOLOGY

President: Prof. H. R. DEAN, LL.D., M.D., F.R.C.P. (Cambridge).

Vice-Presidents: Prof. DOROTHY RUSSELL, M.D., M.R.C.P. (London); R. J. N. GREAVES, M.D. (Cambridge). Prof. W. G. BARNARD, M.C., F.R.C.P. (London).

Hon. Secretaries: G. P. McCULLAGH, M.D., 282, Hills Road, Cambridge; C. J. C. BRITTON, M.D., 121, Harley Street, W.1.

Official Reporter: Dr. A. G. SIGN.

Meeting-place: Pathology Dept., entrance Tennis Court Road.

Wednesday, June 30.—10 a.m. to 11.30 a.m. Discussion: Recent Advances in Our Knowledge of the Rhesus Factor. To be opened by Prof. D. F. CAPPELL, M.D. (Glasgow), followed by P. L. MOLLISON, M.D. (London), and R. R. A. COOMBS, Ph.D. (Cambridge). 11.30 a.m. to 1 p.m., *Occasional Papers:* The Thymus in Myasthenia Gravis, by A. B. BRATTON, D.S.O., M.C., M.B. (London). Streptomycin and the Laboratory, by M. H. GLEESON-WHITE, M.B. (Cambridge). Some Chemical Changes Associated with Cellular Damage, by K. C. DIXON, Ph.D. (Cambridge). The Electrophoretic Fractionation of the Serum Proteins and its Relationship to Immunity and Treatment, by N. H. MARTIN, M.B. (London). *Afternoon Demonstrations.*

Thursday, July 1.—10 a.m. to 11.30 a.m., Discussion: Acute and Subacute Hepatitis. To be opened by Prof. H. P. HIMPWORTH, M.D., F.R.C.P. (London). Followed by Prof. J. H. DIBLE, M.B., F.R.C.P. (London). G. W. M. FINDLAY, C.B.E. Sc.D., M.D. (London), and J. A. R. MILES, M.B. (Cambridge). 11.30 a.m. to 1 p.m., *Discussion:* On the Prophylaxis of Viral Infections, with special reference to the Use of Vaccines. To be opened by C. H. ANSTEWEN, M.D., F.R.C.P., F.R.S. (Hampstead), followed by Prof. R. HAFE, M.D. (London). Prof. W. I. B. BEVERIDGE, D.Sc. (Cambridge), and M. G. P. STOKER, M.D. (Cambridge). *Afternoon Demonstrations and visit to Strangeways Laboratory.*

PHYSIOLOGY, INCLUDING BIOCHEMISTRY

President: Prof. A. C. CHIBNALL, F.R.S. (Cambridge).

Vice-Presidents: Sir PERCIVAL HARTLEY, C.B.E., M.C. F.R.S. (London); E. E. POCHIN, M.D., F.R.C.P. (London); Prof. J. N. DAVIDSON, M.D., D.Sc., F.R.S.E. (Glasgow). Prof. E. C. DODDS, M.V.O., F.R.S., F.R.C.P. (London). Prof. HENRY BARCROFT, M.D. (Belfast).

Hon. Secretaries: R. H. WINFIELD, D.F.C., M.B., Ch.B., St. John's College, Cambridge; Prof. F. DICKENS, F.R.S., Courtauld Institute of Biochemistry, Middlesex Hospital, W.1.

Official Reporter: Mr. H. COOPER.

Meeting-place: Physiology Dept., entrance Downing Street or Downing Place.

Wednesday, June 30.—10 a.m., Discussion: Recent Work on Proteins and its Medical Applications. To be opened by Prof.

A. C. CHIBNALL, Ph.D., Sc.D., F.R.S., followed by Dr. J. A. V. BUTLER, D.Sc., F.R.I.C., Methods of Isolation and Characterization of Individual Proteins; Dr. L. COLEBROOK, F.R.C.O.G., F.R.S., Plasma and Blood Derivatives in the Treatment of Burns; Prof. E. C. DODDS, M.V.O., D.Sc., M.D., F.R.C.P., F.R.S., Protein Hormones; Prof. G. PICKERING, F.R.C.P., Hypertension; Prof. N. F. MACLAGAN, D.Sc., M.D., M.R.C.P., Diagnostic Tests Based on Changes in the Serum Proteins.

Thursday, July 1.—10 a.m., Discussions: The Physiological Basis of Neuromuscular Disorders. To be opened by Sir HENRY DALE, O.M., G.B.E., F.R.C.P., F.R.S., to be followed by Prof. F. R. MILLER, F.R.S., University of Western Ontario. The Local Action of Acetylcholine on the Hypoglossal Nucleus and Respiratory Centre; Dr. W. S. FELDBERG, F.R.S., Formation of Acetylcholine and Neuromuscular Transmission; Dr. BERNARD KATZ, D.Sc., Excitation at the Myo-neural Junction; Dr. ANDREW WILSON, Ph.D., Myasthenia Gravis and Diisopropyl Fluorophosphate; Dr. C. A. KEELE, M.R.C.P., Tetraethylpyrophosphate in Myasthenia Gravis; Prof. SAMSON WRIGHT, F.R.C.P., Central Effect of Anticholinesterases; and Dr. G. L. BROWN, M.Sc., F.R.S., Recent Work on Myotonia. *Afternoon:* Exhibits and/or films.

PREVENTIVE MEDICINE

President: G. F. BUCHAN, M.D., F.R.C.P., D.P.H. (London).

Vice-Presidents: ROBERT FRENCH, M.D., D.P.H. (Cambridge); F. HALL, C.B.E., M.D., D.P.H. (St. Anne-on-Sea); H. C. MAURICE WILLIAMS, O.B.E., M.R.C.S., L.R.C.P., D.P.H. (Southampton).

Hon. Secretaries: G. HAMILTON HOGGEE, M.R.C.S., D.P.H., 19, Pine Grove, Totteridge, N.20; E. H. R. SMITHARD, M.D., D.P.H., Lewisham Town Hall, S.E.6; J. F. CANNESSE, M.B., Ch.B., D.P.H., The Guildhall, Cambridge.

Official Reporter: Dr. HAMILTON HOGGEE.

Meeting-place: Geology Dept., entrance Downing Street.

Wednesday, June 30.—10 a.m., Symposium on Preventive Medicine under the National Health Service Act, 1946. To be opened by (1) Dr. H. JOLLES (London), Role of the Hospital; (2) Dr. W. N. PICKLES (Ayr), Role of the General Practitioner; (3) Dr. E. D. IRVINE (Dewsbury), Role of the M.O.H., followed by Mr. H. J. McCURRICH (Hove), Dr. F. GRAY (London), and Prof. R. H. PARRY (Bristol).

Thursday, July 1.—10 a.m., Occasional Papers: (1) Policymelitis, by Dr. W. GUNN (London), with Dr. F. W. BURNING (St. Helens) to start the discussion; (2) Ascertainment and Use of Morbidity Statistics, by Dr. P. A. MCKINLAY (Scottish Health Department), with Dr. J. MADISON (Twickenham) to start the discussion.

RADIOLOGY

President: S. COCHRANE SHANKS, M.D., F.R.C.P., F.F.R. (London).

Vice-Presidents: Prof. J. S. MITCHELL, M.B., B.Chir., D.M.R. (Cambridge); C. G. TEALL, M.D., F.F.R. (Birmingham); ERIC D. GRAY, M.D., D.M.R.E., F.F.R. (Manchester); F. ELLIS, M.D., D.M.R.E., F.F.R. (London).

Hon. Secretaries: F. R. BERRIDGE, M.B., B.Chir., D.M.R., 22, Parkside, Cambridge; J. A. C. FLEMING, F.R.C.S.E., D.R., F.F.R., X-ray Department, St. Thomas's Hospital, S.E.1.

Official Reporter: Dr. J. W. D. BULL.

Thursday, July 1. Meeting-place: Addenbrooke's Hospital, entrance Tennis Court Road.—On this day the Section will be divided into two parts: (a) Radiodiagnosis, (b) Radiotherapy. (a) *Diagnosis:* 10 a.m., The Small Intestine in Nutritional Disorders. Opener: Dr. R. A. GREGORY (Liverpool), The Physiology of the Movements of the Small Intestine; Dr. F. R. BERRIDGE (Cambridge), The Radiological Aspects; Dr. WILFRED SHELDON (London), Coeliac Disease; Dr. D. A. K. BLACK (Manchester), Sprue. 2.30 p.m., Dr. KEMP HARPER (London), The Pancreas—Calcification, Calculi, and Cysts; Dr. C. J. C. G. HODSON (London), Uraemic Pneumonia. *Cinema Films:* Movements of the Alimentary Tract in Experimental Animals; Effect of Drugs on Gastro-Intestinal Motility; Gall-bladder Contraction and Evacuation Caused by the Hormone "Cholecystokinin." (b) *Radiotherapy:* 10 a.m., Radioactive Isotopes. To be opened by Prof. O. R. FRISCH (Cambridge), The Physical Aspects; Dr. A. S. MCFARLANE (Hampstead), Radioactive Isotopes as Tracers; Prof. J. S. MITCHELL (Cambridge),

The Radiotherapeutic Aspect of Radioactive Isotopes. 10 a.m. to 1 p.m. and 2.30 p.m. to 5 p.m., *Demonstrations—Radiotherapy*: (1) Radiotherapy Department, Addenbrooke's Hospital; (2) University Department of Radiotherapy, Downing Site.

Friday, July 2 (Joint Meeting of Section of Radiology with Section of Child Health). *Meeting-place*: Large Lecture Theatre, Dept. of Agriculture, entrance Tennis Court Road or Downing Street.—10 a.m., *Discussion*: Malignant Disease in Infancy and Childhood. To be opened by Prof. WILFRID GAISFORD (Manchester), followed by Dr. C. G. TEALL (Birmingham), The Radiological Diagnosis of Malignant Disease in Children; Prof. J. S. MITCHELL (Cambridge), Radiotherapy of Malignant Disease in Childhood; Dr. A. M. BARRETT (Cambridge), The Pathology of Malignant Disease in Childhood.

The following Sections will meet on One Day:

ANATOMY AND ANTHROPOLOGY

President: Prof. H. A. HARRIS, M.D., M.R.C.P. (Cambridge).

Vice-Presidents: Prof. F. WOOD-JONES, F.R.S., F.R.C.S., F.R.A.C.S. (London); W. L. H. DUCKWORTH, M.D. (Cambridge); Prof. W. C. OSMAN HILL, M.D. (Edinburgh).

Hon. Secretaries: D. V. DAVIES, M.B., B.S., 42A, Newnham Road, Cambridge; ALBERT PEACOCK, M.B., B.S., 157, Denmark Hill, S.E.5.

Official Reporter: Prof. H. A. HARRIS.

Meeting-place: Anatomy Dept., entrance Tennis Court Road.

Friday, July 1.—10 a.m., *Discussion*: The Present Position of Primate Anatomy. To be opened by Prof. F. WOOD-JONES (London), followed by Prof. H. A. HARRIS, Radiographic Anatomy of the Primates; Prof. W. C. OSMAN HILL (Edinburgh), The Position of the Prosimians; Prof. S. ACCOMMODATION IN CAMBRIDGE

As mentioned in the *Supplement to the British Medical Journal* of Feb. 28 (p. 31), the lodging accommodation avail-
able in Cambridge is very restricted owing to the incidence
of a number of functions round about the period of the
Meeting.

In order that as much accommodation as possible may be
at our disposal, the Cambridge Executive has booked all avail-
able space in advance. The Colleges have most generously
come to our aid and have offered rooms which, with the lodg-
ings already booked in advance, should accommodate about
2,500 persons.

The following is a brief outline of the position and the steps
which should be taken by those wishing to book rooms through
the Cambridge Executive.

It should be noted that, except for odd rooms falling vacant,
no hotel accommodation is now available, and, except for
rooms already booked by the Cambridge Executive, there are
few, if any, reasonable lodgings to be had. But members are
of course at liberty to make their own arrangements for
accommodation.

If visitors wish the Cambridge Executive to book rooms for
them it is very important that the form on p. 165 of this issue
should be completed and returned as soon as possible to the
Executive Officer, Local B.M.A. Office, Guildhall, Cambridge.
When rooms conforming as nearly as possible to requirements
have been booked, applicants will receive a note giving particu-
lars of the accommodation booked and the charges. A cheque
for the amount indicated should be sent to the B.M.A. Office,
Guildhall, Cambridge, on receipt of which the booking will be
considered definite. This procedure is necessary, as it was
only possible to retain the lodging space by firm booking at
the end of last year. Cheques should be made payable to the
British Medical Association and crossed.

Official Headquarters will be in Newnham College, which
will accommodate 100 men or women—either members of the
B.M.A. or their wives or other guests. All rooms are single
bedrooms, and little or no bedroom service can be given. Full
board will be provided and a lounge set aside for the use of
members and their friends.

Other Colleges have offered accommodation as follows:

Caius	100 men
Christ's	80 men
Corpus Christi	50 men
Downing	60 men
Emmanuel	100 men
Girton	150 men or women
King's	50 men, and 20 men or women in Hostel
Jesus	100 men
Magdalene	60 men
Newnham	20 women (for own members in addition to 100 stated above)
Pembroke	50 men
Peterhouse	50 men
Queens'	100 men
Trinity College	200 men
Trinity Hall	50 men
St. Catharine's	100 men
Selwyn	120 men
Sidney Sussex	80 men
St. John's	200 men
Wesley House	17 men and 6 women
Westminster	35 men or women

ACCOMMODATION AT CAMBRIDGE

JUNE 12, 1948

Each College wishes preference to be given to its own members, and, in the case of Wesley House, Methodist doctors will receive first priority.

The charge for all Colleges, including Newnham, is £1 2s. per person per day, with full board. All rooms are single, and no women can be accommodated except in Newnham. In Birton, King's Hostel, Wesley House, and Westminster. In many cases, therefore, wives may have to be put up in lodgings separate from their husbands.

Rooms in lodgings in town are, in general, available for either men or women, and accommodation for approximately 50 has been reserved. Only bed and breakfast can be provided except in a few isolated cases, but arrangements have been made to reserve space in restaurants and elsewhere for lunches and dinners. The uniform charge for lodgings is 9s. per person per night, including breakfast.

Ration books or emergency cards must be brought, and no meals can be provided in lodgings or Colleges without these. If visitors are going to stay in College they must bring ration books, and if in lodgings emergency ration cards are necessary. Visitors are strongly advised to obtain emergency ration cards before leaving home as Cambridge Food Office will be overloaded in June and very great delay might occur in obtaining emergency cards here.

Towels and soap should be brought, as in the majority of cases these cannot be provided.

the Council, while continuing the central grant, has decided that members attending the Annual Meeting (other than members of the Representative Body) should be asked to pay a fee of one guinea towards the expenses of the meeting.

The fee of one guinea will be payable when members register at the Reception Room, Cambridge.

When completed, the following form should be sent to the Executive Officer, Local B.M.A. Office, Guildhall, Cambridge

B.M.A. ANNUAL MEETING

CAMBRIDGE, JUNE 25 to JULY 2, 1948

Form of Application for Accommodation

NAME (Block Letters)

ADDRESS (Block Letters)

CAR PARKING ARRANGEMENTS

A private car park has been set aside for the use of B.M.A. members, at Coe Fen, Entrance from Fen Causeway from the main road, June 24 to July 3. Attendance will be on duty during the day and admission is free to Members displaying the B.M.A. parking label or badge.

Visiting Members are asked to mark the car with the B.M.A. parking label and not to use them for other purposes. The parking label should be displayed in the car, and not to use them for other purposes.

The police ask that members should be brought to the Guildhall, and no parking will be allowed in the streets of the town. Members should be brought to the Guildhall, and no parking will be allowed in the streets of the town.

Members should be brought to the Guildhall, and no parking will be allowed in the streets of the town. Members should be brought to the Guildhall, and no parking will be allowed in the streets of the town.

REGULATIONS REGARDING DRESS

Academic Dress—At the Annual Meeting, Cambridge, June 25 to July 2, 1948, the following regulations apply: Robes (scarlet, if available) should be worn by all members of the Council and the President's Reception Committee. The Vice-Chancellor's Reception Committee should wear black robes. Reception, Wednesday, June 24, 1948, at 7.30 p.m. Thursday, July 1, 1948, at 7.30 p.m. Ravenscroft, Ltd., 93, The Quadrant, Cambridge, in advance, if desired.

Evening Dress—Evening dress should be worn at the President's Reception, Wednesday, June 30, 1948, at 7.30 p.m. at the Representatives' Dinner, Friday, July 2, 1948, at 7.30 p.m. Dance, Friday, July 2, 1948, at 7.30 p.m.

BADGES

Officers of the Scientific Section should wear Special badges at the Registration, Guildhall, Cambridge.

REGISTRATION FEE AT ANNUAL MEETINGS

The expenditure arising in connection with the Annual Meeting has in the past been met from a guarantee fund raised by the local profession, supplemented by a grant from the Council of the Association. The Council considers that the time has come when the proportion of the expenses falling upon the local profession should be minimized. With this object in view

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization

Metropolitan Borough Councils—Fulham, Hackney, Poplar, Non-County Borough Councils—Dartford, Radcliffe (limited to future appointments), Tottenham, Walsend, Urban District Councils—Denton, Droylsden, Houghton-le Spring, Huyton-with-Roby, Portlaid, Redditch (restricted to new appointments), Tyldesley.

RETURN TO PRACTICE

The Central Medical War Committee announces that Mr. Philip Reading, M.S., F.R.C.S., has resumed civilian practice at Keats' House, St. Thomas's Street, London, S.E.1 (Hop 0151-0152).

GENERAL MEDICAL COUNCIL

SUMMER SESSION

The summer session of the General Medical Council opened at 44, Hallam Street, London, on Tuesday, May 25, Sir Herbert Lightfoot Eason, C.B., C.M.G., presiding.

Dr. Sydney Smith was elected Chairman of Business for 1948-9.

PRESIDENT'S ADDRESS

The President addressed the Council as follows:

This is the 173rd session of the Council, and I am happy to report again that there has been no change in the membership of the Council since our last session.

The Council will, I am sure, desire me to congratulate Sir Leonard Parsons on its behalf on his election into the Fellowship of the Royal Society, an honour which he has well earned by his distinguished studies on child health and the wasting disorders of children.

The *British Pharmacopoeia, 1948*—the seventh—has now been approved by the Pharmacopoeia Committee of the Council in the discharge of the duty entrusted to it by the Standing Orders to deal with all matters relating to the preparation and publication of the book. The Committee approved arrangements for the circulation and inspection of advance copies of the book which were made available in April, and for its publication with effect from Sept. 1, 1948.

I do not wish to anticipate what has been said in the preface to the new *Pharmacopoeia*, but I cannot let this occasion pass without expressing the gratitude of the Council to the Chairman and the members of the British Pharmacopoeia Commission, who have completed a more complex and laborious task than the preparation of any of the previous *Pharmacopoeias*.

Both before and since the Council met in November the office has been heavily engaged in the extra work arising under the Medical Practitioners and Pharmacists Act which was passed on Dec. 18, 1947. The Council has delegated the administration of the Act to the Executive Committee. It may therefore be of interest to members as a whole to have some details of the amount of work and the kind of problems to which the Act gives rise.

Temporarily Registered Practitioners

Its primary purpose, as everyone here will remember, is to settle the position of practitioners temporarily registered by virtue of Defence Regulation 32B or of the Polish Resettlement Act, 1947. The total number of practitioners registered is 4,561, of whom about 4,200 are required under the Defence Regulation. But Parliament has decided that the Council can give a direction for registration under the new Act only in the case of a person who is resident in the United Kingdom and is so resident otherwise than for a temporary purpose. Very few, therefore, of our colleagues will need our help in our extreme: from the first days of the war, in which unfortunately we have no precedent, registration under the Medical Act, 1886, and from the United States of America, to wish or be able to do so, and the Polish Resettlement Act, fulfilling this condition.

It follows that Section 2 of the Act, which provides for the registration without limit of time of practitioners who are registered temporarily, will in fact apply almost exclusively to practitioners qualified on the continent of Europe, who found refuge in this country, often long before the outbreak of the recent war, and have augmented the strength of the profession by service under the Defence Regulation either with armed Forces or, as is more usual, in hospitals, and as assistants to practitioners registered otherwise than temporarily.

Between 900 and 1,000 of these practitioners have applied for registration under the new Act, those whose qualifications had to be recognized by the Council before they could be registered under the Defence Regulation—namely, those registered in the first instance for service in hospitals, etc., or as assistants—have been required by Parliament to fulfil only one condition beyond that of residence in the United Kingdom. This condition is that they must satisfy the Council that they

have rendered satisfactory service in a medical capacity whilst temporarily registered.

Those whose qualifications did not have to be recognized by the Council before they could be registered under the Defence Regulation—namely, those registered in the first instance for service with armed Forces—must in addition satisfy the Council that they hold qualifications which sufficiently guarantee professional competence.

The Council will not be surprised to hear that the Executive Committee considers registration in the *Medical Register* without limit of time a valuable privilege. The Act, by providing an appeal to the Privy Council against a refusal by the Council to register, secures that this privilege will not be capriciously withheld from an applicant. The requirement that an applicant under Section 2 must fulfil the condition that his previous service has been satisfactory seems to the Committee to show no less plainly that this privilege is not to be conferred after any perfunctory examination of an applicant's record of service, but only after satisfactory answers have been received to references made on behalf of the Committee to the hospitals or other institutions or services, or to the practices, in which he has worked, or to the authorities of any armed Forces in which he has served; to the Central Medical War Committee, as the advisers of the Government on the maintenance of an adequate medical service for civilians during the war; to the Ministry of Health; and to the Home Office as the Department concerned with aliens.

References on this scale make much work and must take time to complete. While some practitioners temporarily registered early in the war have been in some circumstances on one or two posts ever since, it is not uncommon for others to have served in 20 or 30 hospitals, etc., or practices, and at least one applicant has been in as many as 60 posts.

I find that at least 1,500 letters have been sent on behalf of the Council to bodies and persons concerned for evidence of satisfactory service. While nearly all the letters, it is true, are in confirmation form, all of them must it is possible be correctly addressed, and the verification of names and addresses given to applicants has been no light task in itself. Extracts reproduced to confirm process from about 750 applications have been sent to the Central Medical War Committee and the civil department concerned, and reference has been made to the appropriate Service Department in nearly 200 cases in which the practitioner has served in armed Forces.

The Council has received willing and welcome help both from private correspondents and from the public bodies on whose assistance it depends in this matter. But the verification of service mainly given under war conditions is a laborious process for the departments and others concerned with the numbers of applications, and it is obvious that particular applicants may feel that it takes much too long to get registered.

Since the number of applicants under Section 2 so far registered is to-day, more than five months after the passing of the Act, only between 100 and 200, I am not myself disposed to think that the position could not be more satisfactory. But I hope that by explaining for the information of all concerned the precautions which the Executive Committee thinks it is its duty to take before directions for registration under the Section are given I have made it clear that such a direction cannot properly be given in any case until the Committee has evidence of satisfactory service, which has to be obtained by it from other persons and bodies.

Practitioners temporarily registered by virtue of the Polish Resettlement Act, 1947, have also been required by Parliament under Section 2 to fulfil the condition that their professional service whilst so registered has been satisfactory. Since that Act was not passed until March, 1947, the period of service in question is short, and the Executive Committee hopes to be able to deal quite expeditiously with the applications in this category, of which there cannot be more than about 300.

Service Outside the United Kingdom

As the Council is aware, the Act includes, in addition to the provisions affecting practitioners now temporarily registered, provisions in favour of practitioners not so registered.

Section 3 enables the Council to give directions for the registration of practitioners who, after Sept. 1, 1939, have served

professionally outside the United Kingdom in any of His Majesty's Forces (including Dominion, Indian, and Burma Forces). The conditions as to residence in the United Kingdom and evidence of satisfactory professional service of which I have already spoken apply to these practitioners, who are further required to fulfil conditions as to the recognition by the Council of their qualifications and as to evidence of character.

The Section also applies to practitioners who, after Sept. 1, 1939, served professionally outside the United Kingdom in any voluntary organization operating in connexion with any of the Forces, and to practitioners who gave professional care to British subjects or British protected persons in territories under British jurisdiction during war operations, enemy occupation, or the continuance of circumstances arising therefrom.

About 60 applications under the Section have at present been received. I feel it right to say that unless any difficulty arises about the fulfilment in particular cases of any other relevant condition, the Executive Committee recognizes a special obligation to deal with these applications as soon as evidence of satisfactory service is placed in its hands by the competent authorities.

The other provision of the Act for registration in the *Medical Register* without limit of time is Section 4, which applies to practitioners not covered by Sections 2 and 3 who, before Aug. 4, 1947, have been permitted to enter, or to remain in, the United Kingdom in view of circumstances attributable to war, and to certain Polish practitioners who arrived in this country too late to secure registration under the Polish Resettlement Act, 1947, which expired on Dec. 31, 1947.

Parliament has recognized that the quality of recruits to the profession under Section 4 must in the first instance be a matter of speculation, for they are not only required to fulfil the conditions as to residence in the United Kingdom, recognition by the Council of their qualifications, and evidence of character, already enumerated; they must also obtain professional employment in this country which must be in a hospital or other institution approved under the Section, or, if they are Polish practitioners, otherwise under supervision; and if their applications are successful their registration is in the first instance to be provisional, limited in time to a period of not less than six and not more than 18 months, and limited in scope to the purposes of their employment under the Section.

About 40 applications have at present been received from practitioners who purport to be entitled to benefit by the main provisions of the Section. These applications will require careful scrutiny by the Executive Committee. The number of applications by Polish practitioners not temporarily registered under the Polish Resettlement Act, 1947, with which the Committee expects to have to deal is also small.

"Commonwealth Practitioners"

The work of the Executive Committee and of the Council's officers under all the sections of the Act which I have mentioned will not (apart from the provision made by the Act for the admission of late applications) last more than a certain time, since it is concerned with the settlement of the position of practitioners now registered temporarily, and of other practitioners whose service or sufferings under war conditions are thought by Parliament to give them claims to special consideration for establishment in the profession here.

The only provisions of the Act which will, broadly speaking, be permanent in operation are those of Section 9, which enables us at last to discard the obsolete description "Colonial" practitioners and to use the description "Commonwealth" practitioners for persons registered by virtue of qualifications granted in the British Commonwealth of Nations elsewhere than in these islands; and those of Section 8, which brings into being a new kind of temporary registration.

The object of the Section is to enable visiting teachers of medicine and postgraduate students not otherwise registrable in the *Medical Register* who take temporary posts in hospitals in the United Kingdom to enjoy the status of registered medical practitioners for the purposes and for the duration of their appointments.

I need not say more about this, the last of the main provisions of the Act, than that it will relieve a number of practi-

tioners who are welcome guests here, some already eminent and all qualified elsewhere, from the position of being "unregistered persons," which some of them have felt to be intolerable and will at the same time relieve the hospitals, their hosts, from certain anxieties arising out of that position.

I do not think the Council would wish me to omit from my address an expression of our hope that time may be found during the next Session of Parliament for the passage into law of a Bill amending the Medical Acts on the lines of the draft Bill submitted by the Council to the Minister of Health. As I said in my address last November, this short draft Bill included not only important provisions based on recommendations of the Goodenough Committee but also provisions giving practitioners a right of appeal to the courts against penal erasure from the *Medical Register*; giving the Council statutory power which it does not at present possess, to restore the names of practitioners to the Register after penal erasure; enabling the Council to take evidence on oath and to compel the attendance of witnesses by subpoena; and enlarging the direct representation of the profession on the Council. I repeat that the enactment of such provisions as these would, I believe, commend itself alike to the profession and to the public.

In addition to the educational business which will come before the Council, there are 16 medical disciplinary cases which will have to be considered. As usual, after some considerable experience of the proceedings of the Council, I can make no prophecy as to when the session will end.

DISCIPLINARY PROCEEDINGS Alleged Misleading Certificate

The Council on May 26 considered the case of Dr. Cecil Thomas, registered as of Hengoed, Glam., who was summoned on the charge that he had given a certificate for the purpose of excusing a certain Mrs. Oaten from attendance in a court of justice. The certificate, dated Oct. 1, 1947, stated that Mrs. Oaten "is suffering from pregnancy and is due to be confined early in December, and is not able to travel." It was alleged that Dr. Thomas did not see or examine Mrs. Oaten at the time he gave the certificate; the only occasion on which he had seen her—and then he did not examine her—was some four weeks before the certificate date.

Dr. Thomas attended, accompanied by Mr. Oswald Hempson, appearing on behalf of the Medical Defence Union.

Mr. F. P. Winterbotham, solicitor to the Council, said that Mrs. Oaten had been summoned to appear in connexion with some legal proceedings at Devizes, but the certificate was submitted, and the proceedings had to be postponed. The Recorder caused inquiries to be made, and as a result of them made a formal complaint to the Council. It appeared that in August Mrs. Oaten had attended at a child-welfare clinic and was seen by the nurse, who thought she was pregnant, but a more complete examination was arranged a week later, and then the nurse formed the view that she was not pregnant. Mrs. Oaten would not believe it, and went to the surgery of Dr. R. A. Phillips, of Hengoed, whom she had never previously visited, and stated that she was pregnant and required a certificate for additional rations. Dr. Phillips, though he did not make a vaginal examination, was convinced from the woman's appearance and from her history that she was pregnant, but as he had not a form of certificate at hand at the moment he asked her to call again in a day or two. When she did so she saw Dr. Phillips's assistant, Dr. Thomas, who, after questioning her, gave her the certificate. On the basis of her statement that she had had amenorrhoea since March, he placed the expected date of confinement as early in December. On Sept. 15 Mrs. Oaten attended by the officer in charge, Dr. Philomena Garfield Evans, who gave it as her opinion that she was not pregnant, an opinion which she confirmed on a further examination six weeks later. On Oct. 1 Mrs. Oaten's husband came to Dr. Thomas's surgery, said that his wife was called upon to give evidence in a court of law at Devizes, and asked for a certificate that owing to pregnancy she was unfit to travel from Glamorgan to Wiltshire. This certificate was given, and was the subject of the charge.

Miss Margaret Humphrey, a midwife employed by the Glamorgan County Council, testified that she examined Mrs. Oaten, and found that, although she had the appearance of pregnancy, including enlargement of abdomen and breasts and morning nausea, she was not actually pregnant.

A statutory declaration by Dr. Garfield Evans was put in stating that on examining Mrs. Oaten she could find no definite sign of pregnancy. The stomach was fat and flabby, there was some tenderness over the left fornix, and per vaginam there appeared to be some thickening over the left tube.

In a letter to the Council when the charge was brought forward Dr. Thomas stated that Mrs. Oaten came to the surgery, stating that she had consulted his principal a few days previously and he had expressed the view that she was pregnant, but that she was to call again for a food certificate. Dr. Thomas, on the strength of her appearance and her history, gave her the certificate; the conditions in the surgery were not suitable for a vaginal examination four weeks later her husband came for a further certificate, and in view of the fact that she would be then in the seventh month of pregnancy he had no hesitation in saying that she was unfit to make a long journey.

In evidence Dr. Thomas said that he had given the certificate in perfectly good faith. The woman's appearance tallied with her story. She firmly believed herself to be pregnant.

The President: How did you know on Oct. 1, not having seen her since early September, that she was still pregnant? She might have had a miscarriage.

Dr. Thomas: In that event she would not have needed this certificate. She would have been even less fit to travel.

Dr. Ronald Arthur Phillips of Hengoed, said that Dr. Thomas had been with him for two years as an assistant and had been entirely satisfactory; he was conscientious in every way. With regard to the examination of Mrs. Oaten, when he first saw her he had no doubt that she was pregnant. She told him that her last period was in the previous March. The swelling of the abdomen and other signs suggested pregnancy. It was not his custom to carry out examinations on women in his surgery if they came alone. Later, on Oct. 17, he saw the woman again at the request of the police and carried out a complete examination. The swelling of the abdomen then corresponded to a five-months pregnancy but it was soft and gave under pressure. He revised his earlier opinion and now came to the conclusion that it was one of those rare cases of pseudopregnancy. Dr. Phillips added that if he instead of Dr. Thomas had been at the surgery at the time he would have given the certificate as Dr. Thomas had done.

Mr. Hempton said that in many of the cases in which he appeared at the General Medical Council he had to apologize for errors. In this case he offered no apology. It was very hard on his young doctor that he should have to appear on a charge of inferior conduct in a professional respect based on such stuff as this. This woman, who had every appearance of pregnancy, went to Dr. Thomas for a certificate, having already been seen by Dr. Thomas's principal and senior, who had expressed the view that she was pregnant. Everything was compatible with that statement. Mrs. Oaten herself was convinced. There was no evidence of an attempt on her part to deceive the doctors. If the Council condemned Dr. Thomas "none of you are entitled to accept the opinion of a consultant without confirming it yourself. Has it been done more than would have been done by any of you? I am sure it has—the end that the diagnosis of pregnancy had been wrong and that the doctors had been similarly deceived by pseudopregnancy."

The Council, after considering the evidence, found that the certificate was issued in good faith, and that they did not find Dr. Thomas guilty of any offence in a professional respect. The case was accordingly dismissed.

Drug Offences

The Council considered the case of Dr. Raymond Llewellyn Evans, registered as of Swansea Road, Haver, who was convicted as the result of two convictions. The first conviction was for unlawfully failing to enter in a register the particulars set out in the Dangerous Drugs Regulations. The second conviction was with respect to ever quantities of ever drugs or preparations he had obtained and supplied. The third conviction was for applying concerned three offences of unlawfully procuring, supplying and having possession of drugs while not being authorized contrary to the provisions in the Regulations.

Mr. Winterbotham stated that with regard to the first conviction in 1941 Dr. Evans was charged with 11 offences, of them being that he had procured a certain preparation for himself. Seven of these charges were adjudged proved, but three of them he was bound over on condition that he undergo treatment at the Maudsley Hospital or similar institution. The seventh charge was the one now before the Council. The second conviction in 1947 was of a different character. The police had their attention drawn to the fact that although his authorization had been revoked by the Home Secretary he had in fact purchased various amounts of

in the drug register. His explanation was that he was under the impression that the withdrawal of his authorization by the Home Secretary was for twelve months only. The police said that there was no evidence available to show that he had used these drugs for himself or for any improper purpose.

Dr. Evans stated to the Council that in 1941 he was subject to abnormal domestic worries and took certain drugs for himself. When he was before the magistrate he was told that he would be banned from obtaining drugs for the one year during which he was bound over, and when subsequently he received the notice from the Home Secretary withdrawing his authorization he had supposed that this was for one year only. He became a works doctor for some years, in which position he did not need to use dangerous drugs. He had known nothing about the possibility of applying for restoration of the authority, and on entering general practice he had obtained drugs for his patients in the usual way, and had been very careful to make the proper entries in the register. He had entirely given up any taking of drugs during the last eight years.

The Council decided not to direct erasure and dismissed the case against Dr. Evans.

The case next considered was that of Dr. Malcolm Andrew Graham-Yooll, registered as of Pembroke, who was summoned on the charge that he had been convicted at Portsmouth in 1943 of not keeping a register as required under the Dangerous Drugs Regulations, and at Pembroke in 1947 of failing to enter in a register the true particulars of drugs and preparations obtained by him on six dates. Mr. Winterbotham said that on the first of these convictions it was shown that Dr. Graham-Yooll had obtained 284 morphine sulphate tablets from the chemist, and when interviewed he had said that the drugs were obtained for use in emergency, and he had not thought it necessary to keep records.

Dr. Graham-Yooll said that before and during the war he was in the Royal Naval Medical Service with certain periods of leave during which he accepted appointments as a locum tenens. It was stated that during the war a sufficient quantity of drugs was supplied by each Service to medical officers. This was correct, officials being on many occasions supplies were either realized entirely as a result of enemy action or were inadequate. For example, in November 1941 when H.M.S. Adventure was badly damaged by a magnetic mine and its medical department, including dispensary and stores, completely wrecked, with casualties 57 killed and 143 wounded. He had similar experiences elsewhere, and also during the bombing of Plymouth and Devonport. He had endeavoured, therefore, to obtain emergency supplies of drugs to be held in reserve and he had not at the time supposed that it was necessary to register these. As regards the second conviction, since taking over a practice at Pembroke he had been exceedingly busy, and had to attend all kinds of emergencies over a scattered country. He admitted that his entries in the register contained a number of errors, relatively and actually, only a small amount of the drugs in question. He pleaded guilty to carelessness.

The Council postponed judgment on the case until May, 1949, but said that they would require Dr. Graham-Yooll to attend at their session in May, 1949, bringing with him evidence as to his conduct in this matter in the interval.

The next case was that of Dr. Brendan O'Carroll, registered as of Onslow Square, S.W., who appeared on the charge that in October 1947, at Swansea he had been convicted, after pleading guilty, of procuring, otherwise than in accordance with his authority certain amounts of cocaine hydrochloride, cocaine alkaloid, and morphine sulphate, contrary to the Dangerous Drugs Regulations, and had been sentenced to seven days imprisonment. The drugs had been discovered to be missing from the dispensary of a hospital at which Dr. O'Carroll was temporarily employed, and the key of which had been entrusted to him. He had admitted taking the drugs for his own use, as he was dismissed from the hospital, the police-court proceeding following.

Dr. O'Carroll had previously appeared before the Council in 1942, after a conviction of being in charge of a motor-vehicle while under the influence of a drug. The Council on that occasion erased his name from the Register, to which it was restored in 1946.

He now stated to the Council that he had just completed a period of six months' treatment in Shenley Hospital, in view of the fact that his authorization under the Dangerous Drugs Act had been withdrawn so that his one weakness could not be any danger in future, he asked to be put on probation for a year.

The Council found the misdemeanour proved, and directed the Registrar to erase the name of Brendan O'Carroll from the Register.

Other Cases Arising from Convictions

The Council considered the case of Dr. James Kirkness, registered as of Warrender Park Crescent, Edinburgh, who was summoned on the charge that he had been convicted at Edinburgh in December last of breach of the peace and assault and had been fined £5. Dr. Kirkness attended, accompanied by Mr. Alan Fletcher, counsel.

Mr. Winterbotham said that the offence, which was followed by the conviction, arose out of an incident in the night nurses' kitchen and dining-hall in a hospital in Edinburgh when Dr. Kirkness with another man entered, and after some altercation over cigarettes Dr. Kirkness struck one of the nurses on the neck with his glove and put all the nurses into a state of alarm. It was not alleged that Dr. Kirkness or the other man was drunk, though they had had some drink. Dr. Kirkness had been previously before the Council in 1944 on allegations that on two occasions he had been so far under the influence of drink as to be incapable of properly carrying out his duties to waiting patients. Judgment on that occasion was postponed for twelve months, at the end of which time the Council did not see fit to direct erasure.

Mr. Fletcher said that on the occasion in question Dr. Kirkness had been at a family party and was somewhat merry. He went into the nurses's dining-room to get some cigarettes, and one of the nurses, he alleged, was rude to him, and he flicked the girl on the shoulder with his glove. Standing by itself the case would be trivial, though regrettable. He was not in any sense drunk, and had never taken drink to excess since his previous appearance before the Council.

The Council found the conviction proved, but postponed judgment for twelve months.

The next case was that of Dr. James Anderson Edward, registered as of Southsea, who was summoned following two convictions, at Wallsend and at Portsmouth, both in 1946, of driving a motor vehicle whilst under the influence of drink.

Dr. Edward was not present, but Messrs. Le Brasseur and Oakley, on behalf of the Medical Protection Society, represented him. It was stated that he was serving as a ship surgeon. He had written saying that he was on the high seas and that it was extremely difficult for him in that situation to obtain testimonials from his professional colleagues. He thought the Council ought to be satisfied with his discharge book, signed by his captains from time to time. He put in one testimonial to irreproachable conduct.

The President said that there appeared to be no reason why Dr. Edward should not remain at sea and never come before the Council at all.

The Council decided to postpone the case until the May session of next year.

The case of James Alphonsus Heerey, registered as of Virginia, Co. Cavan, in which judgment had been postponed from a previous session, was next taken. Dr. Heerey had been put on probation by the Council following a conviction at Doncaster in 1946 of inflicting grievous bodily harm upon two men and causing damage to property.

Dr. Heerey did not appear, and a letter from the Ministry of Transport stated that he had served as a ship surgeon, but that after an argument with the master and chief officer he had deserted the ship at Brisbane in September last. A letter from Dr. Heerey stated that he intended to remain in Australia and to be registered there if possible. The controversy which led to his leaving the ship arose because the captain was exceedingly unfriendly and interfered with his work. A testimonial was put in from the medical superintendent of the Blue Funnel Line stating that Dr. Heerey's medical work was entirely satisfactory and that he had given the impression of being a very capable doctor.

The Council did not see fit to erase the name from the Register.

Dr. William Belton, registered as of Blakehall Road, Wanstead, in whose case the judgment of the Council had been postponed, following a conviction in 1947 for careless driving and being drunk in charge, and in 1942 the finding by a court-martial that he had been guilty of drunkenness on active service and of unbecoming behaviour, came forward with four testimonials, three of them from professional colleagues in his

neighbourhood, as to his excellent character in the interval and the Council did not see fit to direct the Registrar to erase the name.

Dental Cases

On a report from the Dental Board the Council considered the case of William Grosart, registered as of Moss-side, Manchester, Dentist, 1921, concerning whom the Dental Board had found that he had indirectly advertised and/or canvassed for the purpose of obtaining patients in that he was associated with an unregistered person running a dental repair shop. The Board recommended that his name be erased from the Register. On behalf of Mr. Grosart it was contended that through some misunderstanding his defence was not presented to the Dental Board and he was condemned on the evidence for the complaint alone. The case turned on Dental Board procedure.

The Council, after a long hearing, decided to remit the case to the Dental Board for further inquiry.

On a report from the Dental Board concerning Albert Latham, registered as of Linthorpe Road, Middlesbrough, Dentist, 1921, who had been found, contrary to Article 111 of the Warning Notice of the Dental Board, to have been associated with persons carrying on a dental business who advertised, the Council directed the Registrar to erase the name from the *Dentists' Register*.

Alleged Drunkenness during Professional Attendance

On May 26 and 27 the Council considered the case of Dr. Thomas Elliott, registered as of Morden, Surrey, who was summoned on the charge that while in professional attendance on Mrs. York at Raynes Park he was, on two dates, "so far under the influence of drink as to be incapable of carrying out your professional duties towards her in a proper and seemly manner." The complainant was the husband, Mr. Sydney York, who was represented by Mr. Brundritt, counsel, instructed by Mr. W. Timothy Donovan, solicitor. Dr. Elliott was represented by Mr. Oswald Hempson, appearing on behalf of the Medical Defence Union.

Mr. Brundritt said that Dr. Elliott had been the Yorks' doctor for ten years, during which time no complaint had been made against him. In February last Mrs. York had tonsillitis, developing into a quinsy. On visiting her late at night on Feb. 17, Dr. Elliott, according to Mrs. York and her mother, showed signs of having been drinking. His speech was thick, his breath smelt of alcohol, he dropped a thermometer and a spoon, and his gait was unsteady. He called again on Feb. 19 (the fourth time he had called that day), and on this occasion Mr. York was at home, and, according to Mr. York's story, the doctor was unsure of his footing, his speech was distorted, he threw his case on the bed, and his appearance suggested that he had been drinking. Mr. York told him that in his opinion he was drunk, and that he would "report the matter to the B.M.A." Corroborative evidence was given by a friend of Mr. York who saw the doctor momentarily as he was leaving the house.

Dr. Elliott, in the witness-box, strongly denied the allegations. He remembered the visit on Feb. 19 because of his amazement at Mr. York's accusation. He had finished his evening surgery at about 9 p.m. and motored to Mr. York's flat to give his patient her third penicillin injection on that day. When he left the flat he drove himself home without the slightest difficulty, garaged the car, and after doing some writing went to bed. He had no clear recollection of the earlier visit on which he was said to have been in drink, probably because no complaint was made to him, and he continued without any remonstrance or protest to visit the patient for the next two days. All that he ever took in the evening was a glass of Empire wine.

Evidence was also given by a patient whose child Dr. Elliott had attended late on the same evening on which he had been accused by Mr. York of being drunk. This patient said that Dr. Elliott was perfectly sober and attended to the case with his usual care.

On the second day of the hearing other patients of Dr. Elliott who had been attended by him at the same time as the family who had brought the complaint gave evidence as to his sobriety and attentiveness then as on all occasions, and Mrs. Elliott also bore out her husband's statement as to his sobriety on the evenings in question.

Dr. Elliott was asked by counsel for the complainant whether his partnership with Dr. Orr and Dr. Turnbull had not been terminated owing to that case. Mr. Hempson protested against the question, but it was allowed; and Dr. Elliott replied that

the partnership had been dissolved; but this case was only one of the issues; there had been disagreements over the last two years.

Mr. Hempson in a speech for his client referred to the exceedingly flimsy character of the allegations—that the doctor's speech was thick, that he held on to the banister in going downstairs, that he dropped a thermometer, that he placed his bag on the patient's bed. Small incidents had been exaggerated, and gradually this story had been built up. Dr. Elliott was entitled to ask the Council to say that this complaint had not been established.

Mr. Brundritt, for the complainant, said that this was a simple issue of fact. He agreed that it was important to the respondent, but it was important also to the public that they should not be attended by doctors in a state of intoxication.

After a deliberation *in camera* for no longer than five minutes the Council found the facts alleged against Dr. Elliott not proved to its satisfaction, and dismissed the charge.

Convictions for Misdemeanours

The Council considered the case of Dr. James Scott, registered as of Guilford Street, London, W.C.1, who appeared on the charge that in October, 1947, he had been convicted at Cheltenham of being under the influence of drink while in charge of a motor-car, and there were two earlier convictions against him, at Gloucester in March, 1947, of being found drunk, and in April, 1937 at Leith, of being under the influence of drink while in charge of a motor vehicle. Dr. Scott was defended by Mr. Hempson, appearing on behalf of the Medical Defence Union, who pleaded certain matters in mitigation and put in testimonials. Judgment was postponed for one year.

The case next considered was that of Dr. John Matthew Campbell, registered as of Omagh, Co. Tyrone who appeared on the charge that in 1945 at Crewe and in 1947 at Bury St. Edmunds he had been convicted of driving or of being in charge of a motor-car whilst under the influence of drink. Dr. Campbell apologized to the Council for his lapse which he promised would not occur again. Judgment in this case also was postponed for one year.

The case of Dr. Trevor Owen Williams, registered as of Dudlow Lane, Liverpool, was next considered. He had been convicted on three occasions in Liverpool—in November and December, 1947, and in March 1948—of being found drunk. Dr. Williams expressed his regret and produced testimonials. Judgment was postponed for one year.

The Council considered the case of Dr. Basil Elliott, registered as of St. George, Terrace, Newcastle-upon-Tyne, who appeared in answer to the charge that in 1936 at Jedburgh he had been convicted of certain motor-car offences, one of which was driving or attempting to drive a car whilst under the influence of drink, and in 1948 at Newcastle of driving a motor-car whilst under the influence of drink or of being in such an extent as to be incapable of having proper control of the vehicle. Dr. Elliott was defended by Mr. F. A. V. Porson, solicitor. Mr. Porson on Dr. Elliott's behalf expressed extreme regret for the occurrences. There were very rare transgressions, for, except for such isolated offences, when a doctor is under a disproportionate effect upon him, Dr. Elliott was a technician. He put in a large number of testimonials from medical men in Newcastle testifying to Dr. Elliott's high character, excellent medical work, and popularity with patients. In this case also the Council postponed judgment for one year.

The Council decided to hear in his absence the case of Dr. William Hamilton, registered as of Kilmarnock, Ayrshire, Scotland, on the charge that he was convicted at the Sheriff Court of Ayr in 1946 of failing to keep a register as required under the Dangerous Drugs Regulations. Dr. Hamilton was also charged with having abused the privileges conferred upon him by the Dangerous Drugs Acts and Regulations by giving a number of prescriptions for tincture of opium to a patient who was to his knowledge a drug addict, such prescriptions not being properly required for medical treatment.

The case had been adjourned from two previous sessions in the absence of the practitioner and he did not appear and was not represented on this occasion. Mr. Gerald Howard pre-

sented the facts to the Council. Evidence as to the conviction was given by Inspector James Grant, of the Ayrshire Constabulary.

The Council found that the conviction had been proved and directed the Registrar to erase from the *Medical Register* the name of William Hamilton. It did not pronounce upon the second charge.

Restoration

The Council restored to the *Medical Register* the name of James Samuel Ashe.

The New Pharmacopoeia Commission

Apart from disciplinary business the only matters which came forward in the public sessions were the report of the Examination Committee, which consisted of tables of the annual examination returns for 1947, and the report of the Pharmacopoeia Committee, which was on the publication of the *British Pharmacopoeia 1948*. Dr. Campbell, chairman of the committee, paid a high tribute to the work of the Commission in preparing the book, and spoke particularly of the regret with which the committee parted from its friend and counsellor, Professor Emeritus J. A. Gann, in his capacity as chairman of the Commission. A selection committee had been set up to nominate the chairman and members of the reconstituted Pharmacopoeia Commission with effect from Oct. 1, 1948, and recommended the following: Prof. H. Cohen (clinical medicine), Dr. R. Greene (clinical medicine), Prof. D. M. Dunlop (therapeutics), Prof. A. D. Macdonald (Pharmacology), Dr. A. A. Miles (biological products and assays), Prof. H. Berry (pharmacy), Mr. J. C. Humber (pharmacy), Prof. W. H. Linnell (pharmaceutical chemistry), Dr. R. P. Linstead (general chemistry), Dr. J. R. Nicolls (analytical chemistry). Prof. D. M. Dunlop was recommended as chairman.

The Council approved the recommendations.

WORLD MEDICAL ASSOCIATION

The Council of the World Medical Association held its spring meeting on April 26-29 in the building of the New York Academy of Medicine, where the headquarters of the Association has now been established. Dr. Routley (Canada) presided, and the members present were Prof. E. Marquis (France), Dr. J. Suchlik (Czechoslovakia), Dr. O. Leuch (Switzerland), Dr. D. Knutson (Sweden), Dr. L. H. Bauer (U.S.A.), Dr. J. A. Bustamante (Cuba), Dr. P. Cibrie (France), Dr. A. Hartwich (Austria), Dr. J. A. Pridham (Great Britain), Dr. S. C. Sen (India), Dr. L. G. Tornel (Spain), and Dr. J. Yui (China) deputizing for Dr. King. The Council learned with great regret that the Honorary Secretary, Dr. Charles Hill, had at the last moment been prevented from attending on account of the critical developments in Great Britain in connexion with the National Health Service Act, and it sent to Dr. Hill a message of personal regard and its best wishes for the successful outcome of the British profession's fight for the preservation of its independence.

Any doubts that may have been entertained at the meeting of the General Assembly in Paris last September about the possibility of harmony and co-operation among delegates from countries with widely different points of view in matters of medical service were dispelled by the display at the Council meeting of patience and tolerance in closely argued debates on difficult subjects. The volume of work prepared for the Council's consideration and the instructions for further work given to the secretariat are evidence that the World Medical Association has an important part to play. The Association now has 37 member associations.

The speedy establishment of the Association on a sound financial basis is due in great measure to the generosity of the United States Committee, composed of medical men and industrialists, appointed for the special purpose of supporting and promoting the work of the Association. This committee, which has aroused enthusiasm in all parts of the U.S.A. and has

received financial contributions from many professional organizations, industrial groups, and individual medical practitioners, has guaranteed the Association substantial income for the first five years of its existence, so that its development may not be impeded or delayed by the present financial difficulties of many of its member associations. The first-fruits of this generosity are the acquisition of the premises in the New York Academy of Medicine at 2, East 103rd Street, New York, where the professional atmosphere and spacious meeting-rooms will enhance the dignity of the Association, and the appointment of a paid general secretary with an adequate staff.

The Council, acting on behalf of the General Assembly, has selected for the post of Secretary Dr. Louis H. Bauer, who is a consulting cardiologist, a member of the board of trustees of the American Medical Association, President of the Medical Society of the State of New York, and Editor-in-Chief of the *Journal of Aviation Medicine*. Dr. Bauer will at first devote only part of his time to the post, but if and when the development of the Association's work renders a whole-time appointment desirable he is prepared to consider the acceptance of whole-time duties. The appointment of a general secretary does not disturb the office of honorary secretary, to which Dr. Hill was appointed by the General Assembly. Dr. Hill will continue to hold that office at least until the next meeting of the Assembly, which will be held in Geneva from Sept. 8 to 11, 1948, under the presidency of Dr. J. Stuchlik, of Czechoslovakia. The appointment of Dr. Bauer to the post of General Secretary created a vacancy on the Council, and in accordance with its powers the Council elected Dr. Elmer Henderson (U.S.A.) to fill the vacancy.

War Crimes

The agenda of the meeting covered a wide variety of topics, and only a few can be indicated here; but they will serve to indicate the potential scope of the Association's activities. The Council gave general approval to a memorandum prepared by the Honorary Secretary on war crimes and medicine. This referred to the German betrayal of the traditions of medicine and offered a restatement of the ethical basis of medical practice. The memorandum will be circulated to all national medical associations, together with a factual summary of German war crimes prepared by the United Nations War Crimes Commission. During the meeting the Council learned with horror of an Arab attack on a Jewish medical unit in which doctors, nurses, and patients were massacred, and it immediately issued a declaration condemning such brutality.

Dr. R. L. Coigny, Director of Health of the Preparatory Commission of the International Refugee Organization, attended to describe some of the work his organization was doing in connexion with the resettlement of medical refugees and to seek the assistance of the W.M.A. The Council expressed sympathy with the work of the I.R.O. and requested the General Secretary to obtain information on the extent of the problem, the steps that have already been taken to solve it, and the facilities available in the different countries for the absorption of medical refugees, and to present a factual report for the consideration of the General Assembly.

Another visitor to the meeting was Dr. H. G. Anderson, Medical Adviser of British Medical Missions and representative of the Medical Christian Mission for North America in its overseas activities. He reminded the Council that medical missionaries were pioneers in the international view of medicine, and said that a new emphasis was being given in missionary work to the achievement and preservation of health as distinct from the cure of disease. He asked the W.M.A. to take cognizance of medical missionary work when developing its international activities.

The Association has begun a series of investigations into the conditions of medical practice in the different countries. The report on the first investigation, which concerns the general background of medical practice and the trend of relations between the medical profession and the State, is nearly ready for issue to national associations, and the preparation of the report on an investigation into the standards of medical education has been begun. The subjects of other investigations to be conducted in the near future include specialist and post-

graduate training, the sale and advertisement of patent medicines, and unqualified medical practice.

The Council appointed two small subcommittees, one to study social security in its medical aspects and the other to consider the preparation of an international code of medical ethics. The first is composed of Dr. Cibrie (France), Dr. Leu (Switzerland), and Dr. Pridham (Great Britain), with Dr. General Secretary, Dr. Bauer; and the members of the second subcommittee are Dr. Cibrie and Dr. Pridham, also with Dr. General Secretary.

The value of the World Medical Association in strengthening national professional organization is illustrated by the work Dr. Bustamante, of Cuba, who was instructed by the General Assembly in Paris to endeavour to bring into the Association membership the profession in the Latin-American countries, where many of the medical associations are small and badly organized. As a result of the opportunity of joining a world wide professional organization the doctors in several of these countries are bestirring themselves to form and organize representative national associations which would qualify for membership of the W.M.A. Cuba, Dominica, Ecuador, Peru, Chile and Colombia are now members, and it is expected that after the Pan-American Conference in Lima in December more countries will apply for membership.

Another example of the Association's scope for co-ordinating national activities is a proposal for the promotion of international facilities for exchange visits between medical practitioners and members of their families for holiday and social purposes.

Publication of Journal

One of the most important discussions of the Council meeting concerned the publication of a journal or bulletin to inform member associations of the Association's activities and to describe medical practice and professional life in all parts of the world. The first preliminary bulletin will be published during the summer, but in order to decide upon the form and principles of a permanent periodical a special subcommittee was formed, the members being Dr. Charles Hill (Great Britain) as Chairman, Dr. Bauer, Dr. Hugh Clegg (Editor of the *British Medical Journal*), Dr. Morris Fishbein (Editor of the *Journal of the American Medical Association*), and Dr. Yui (Editor of the *Chinese Medical Journal*). The Council also discussed the possibility of holding a conference of editors of the journals of national medical associations in connexion with the meeting of the General Assembly in September.

A little ceremony varied the business proceedings when the Chinese delegate, Dr. Yui, in offering the greetings of the Chinese Medical Association, presented the W.M.A. with some most interesting gifts. These comprised a scroll in illuminated Chinese characters, a "gourd" such as was carried by ancient Chinese doctors as a symbol of their profession; an ivory "medical lady," which was used as a model for the purpose of diagnosis when male doctors were not allowed to examine women patients, and a set of nine porcelain phials used for Chinese drugs. Dr. Yui also presented a scroll to the delegate of each national medical association represented at the meeting.

The bountiful American hospitality pervaded the whole of the meeting. On each of the three evenings members of the Council were entertained to sumptuous banquets, and an afternoon visit was paid to the famous Presbyterian Medical Centre. The United States Committee, the Board of Trustees of the American Medical Association, the New York Medical Society, and the New York Academy of Medicine all took part in making the meeting a memorable one for the visiting members of Council.

On the afternoon of April 29 most of the members left for a westward tour to Chicago, Rochester, and Minneapolis, during which they were the guests of the American Medical Association, the Mayo Clinic, and some American universities.

The Home Office announces that Dr. Margaret Philippa Posthumus is no longer authorized under the Dangerous Drugs Acts to be in possession of or to supply dangerous drugs.

BRITISH MEDICAL ASSOCIATION

ANNUAL REPRESENTATIVE MEETING AT CAMBRIDGE, JUNE 25-29

MOTIONS AND AMENDMENTS BY DIVISIONS AND BRANCHES

Elections

Motion by METROPOLITAN COUNTIES: That this Meeting strongly deprecates the use of "block voting" at the Annual Representative Meetings of the Association in connexion with the appointment of the Central Council and standing committees of the Association.

Maternity Medical Services under National Health Service

Motion by WORCESTER AND BROMSGROVE: That this Meeting calls for the abolition of the local obstetric committees.

Motion by WORCESTER AND BROMSGROVE: That this Meeting is of opinion that a woman should have the right under the National Health Service to medical attention at her delivery if she so desires.

Fees for Medical Examination for Life Insurance

Amendment by WORCESTER AND BROMSGROVE: That this Meeting is of the opinion that where a domiciliary examination for life insurance is desired the company or society should pay the practitioner an additional fee of 10s. 6d. as well as the proposed 1s. per mile for mileage.

Motion by SOUTH-EAST ESSEX: That all examinations for life insurance should be paid for at a standard rate of a guinea and a half.

Medical Attendance on Trainees at Government Training Centres

Amendment by WORCESTER AND BROMSGROVE: That the fee paid for attendance on trainees at Government training centres should be exclusive of specially expensive drugs or appliances as applies to fees payable to civilian medical practitioners for attendance on members of the Armed Forces and ex-Service pensioners.

Examination of Recruits for Territorial Forces

Motion by WEST SOMERSET: That the Council should press for the retention or re-establishment of civilian medical boards for the examination of recruits for the Territorial Forces.

Form for Examination of Transport Personnel

Motion by SOUTH-EAST ESSEX: That forms for the examination of transport personnel, bus drivers and conductors, etc., should be uniform, should have the amount of the fee clearly stated, and the company or transport authority should be responsible for the payment.

Mileage for Rural Practitioners

Motion by DUMFRIES AND GALLOWAY: That the British Medical Association press the Minister of Health for an adequate mileage fee for rural practitioners.

Formation of Regional Consultants and Specialists (Including Hospitals) Committees and Establishment of a Central Consultants and Specialists Standing Committee

Amendment by WESTMINSTER AND HOLBORN: That this Meeting views with disquiet the existing alarm among consultants as to the Association's proposals for the constitution of the Central Consultants and Specialists Committee and the Regional Consultants and Specialists (Including Hospitals) Committees (paras. 60-62 of Annual Report of Council).

Amendment by WORCESTER AND BROMSGROVE: That the constitution of the Central Consultants and Specialists Committee should include four extra representatives being members of the Association and engaged partly in consultant and specialist practice and partly in some other branch of medical practice, two to be elected by the Representative Body and two otherwise appointed.

Future Position of the Insurance Acts Committee

Motion by EAST NORFOLK: That the British Medical Association proceed forthwith to form an elected committee to take the place of the Insurance Acts Committee and having full powers of negotiation with the Minister of Health on all matters pertaining to general practitioners in the National Health Service.

Trade Union Organization

Motion by WESTMINSTER AND HOLBORN: That the British Medical Association explore the possibility of setting up a body equivalent to a trade union.

Motion by SHROPSHIRE AND MID-WALES: That a medical trade union be formed to protect the interest of the profession in the future with regard to the forthcoming National Health Service.

Mortuary Accommodation and Pathological Facilities

Amendment by SOUTH STAFFORDSHIRE: That the following Recommendation (iv):

That mortuaries be established at central points in each coroner's jurisdiction, under the control of the local health authority, equipped with refrigeration and a separate viewing-room for relatives, the post-mortem rooms being furnished with good lighting, heating, and an ample supply of running water, and with facilities for pathological examinations and the proper collection of specimens for toxicological examination; that the assistance of trained mortuary attendants be made available; that adequate transport facilities for bringing cadavers to the central post-mortem establishment from outlying mortuaries be provided.

be amended to read as follows:

That adequate transport facilities for bringing cadavers to the central post-mortem establishment from outlying mortuaries be provided.

CONSULTANTS AND SPECIALISTS

Central Consultants and Specialists Standing Committee

Motion by BOURNEMOUTH: That the Central Consultants and Specialists Committee shall be an autonomous body, with full powers to determine policy on consulting and specialist and hospital matters and action through the administrative machinery of the Association. The decisions of the committee shall not be subject to approval of the Council or the Representative Body except in so far as they may affect other forms of practice or other aspects of the policy or activities of the Association.

The Central Consultants and Specialists Committee shall have the power to elect its own chairman, who will be *ipso facto* a member of the Council of the Association.

ORGANIZATION

Proposed new Central Consultants and Specialists Committee

Amendment by BOURNEMOUTH: Under "duties and powers of Central Consultants and Specialists Committee" substitute the words "to decide policy and action on" for the words "to report on" in line 1.

Organization of Association

Motion by BOURNEMOUTH: That the constitution of the Association be reviewed to determine whether the organization in Great Britain should be altered (i) to provide a new basis of representation of members, and (ii) to further such collective negotiation and action by the Association as the institution of the National Health Service may make desirable.

Other Motions by Divisions and Branches

Motion by WESTMINSTER AND HOLBORN: That steps be taken by the Council to set up a standing legal committee.

Motion by KENSINGTON AND HAMMERSMITH: That through the *Journal* or in other ways it should be suggested to members of the Association that they might volunteer to do part of the daily work of representatives during B.M.A. executive and other important meetings.

Motion by NENEATON AND TAMWORTH: That this meeting is not satisfied with the present supervision of production or distribution of foods of animal origin and asks the Council of the Association to approach the National Veterinary Association in order that a joint committee of the two bodies may investigate the matter and report to the proper authorities.

received financial contributions from many professional organizations, industrial groups, and individual medical practitioners, has guaranteed the Association substantial income for the first five years of its existence, so that its development may not be impeded or delayed by the present financial difficulties of many of its member associations. The first-fruits of this generosity are the acquisition of the premises in the New York Academy of Medicine at 2, East 103rd Street, New York, where the professional atmosphere and spacious meeting-rooms will enhance the dignity of the Association, and the appointment of a paid general secretary with an adequate staff.

The Council, acting on behalf of the General Assembly, has selected for the post of Secretary Dr. Louis H. Bauer, who is a consulting cardiologist, a member of the board of trustees of the American Medical Association, President of the Medical Society of the State of New York, and Editor-in-Chief of the *Journal of Aviation Medicine*. Dr. Bauer will at first devote only part of his time to the post, but if and when the development of the Association's work renders a whole-time appointment desirable he is prepared to consider the acceptance of whole-time duties. The appointment of a general secretary does not disturb the office of honorary secretary, to which Dr. Hill was appointed by the General Assembly. Dr. Hill will continue to hold that office at least until the next meeting of the Assembly, which will be held in Geneva from Sept. 8 to 11, 1948, under the presidency of Dr. J. Stuchlik, of Czechoslovakia. The appointment of Dr. Bauer to the post of General Secretary created a vacancy on the Council, and in accordance with its powers the Council elected Dr. Elmer Henderson (U.S.A.) to fill the vacancy.

War Crimes

The agenda of the meeting covered a wide variety of topics, and only a few can be indicated here; but they will serve to indicate the potential scope of the Association's activities. The Council gave general approval to a memorandum prepared by the Honorary Secretary on war crimes and medicine. This referred to the German betrayal of the traditions of medicine and offered a restatement of the ethical basis of medical practice. The memorandum will be circulated to all national medical associations, together with a factual summary of German war crimes prepared by the United Nations War Crimes Commission. During the meeting the Council learned with horror of an Arab attack on a Jewish medical unit in which doctors, nurses, and patients were massacred, and it immediately issued a declaration condemning such brutality.

Dr. R. L. Coigny, Director of Health of the Preparatory Commission of the International Refugee Organization, attended to describe some of the work his organization was doing in connexion with the resettlement of medical refugees and to seek the assistance of the W.M.A. The Council expressed sympathy with the work of the I.R.O. and requested the General Secretary to obtain information on the extent of the problem, the steps that have already been taken to solve it, and the facilities available in the different countries for the absorption of medical refugees, and to present a factual report for the consideration of the General Assembly.

Another visitor to the meeting was Dr. H. G. Anderson, Medical Adviser of British Medical Missions and representative of the Medical Christian Mission for North America in its overseas activities. He reminded the Council that medical missionaries were pioneers in the international view of medicine, and said that a new emphasis was being given in missionary work to the achievement and preservation of health as distinct from the cure of disease. He asked the W.M.A. to take cognizance of medical missionary work when developing its international activities.

The Association has begun a series of investigations into the conditions of medical practice in the different countries. The report on the first investigation, which concerns the general background of medical practice and the trend of relations between the medical profession and the State, is nearly ready for issue to national associations, and the preparation of the report on an investigation into the standards of medical education has been begun. The subjects of other investigations to be conducted in the near future include specialist and post-

graduate training, the sale and advertisement of patent medicines, and unqualified medical practice.

The Council appointed two small subcommittees, one to study social security in its medical aspects and the other to consider the preparation of an international code of medical ethics. The first is composed of Dr. Cibrie (France), Dr. Leuch (Switzerland), and Dr. Pridham (Great Britain), with the General Secretary, Dr. Bauer; and the members of the second subcommittee are Dr. Cibrie and Dr. Pridham, also with the General Secretary.

The value of the World Medical Association in strengthening national professional organization is illustrated by the work of Dr. Bustamante, of Cuba, who was instructed by the General Assembly in Paris to endeavour to bring into the Association's membership the profession in the Latin-American countries, where many of the medical associations are small and badly organized. As a result of the opportunity of joining a world-wide professional organization the doctors in several of these countries are bestirring themselves to form and organize representative national associations which would qualify for membership of the W.M.A. Cuba, Dominica, Ecuador, Peru, Chile, and Colombia are now members, and it is expected that after the Pan-American Conference in Lima, in December more countries will apply for membership.

Another example of the Association's scope for co-ordinating national activities is a proposal for the promotion of international facilities for exchange visits between medical practitioners and members of their families for holiday and social purposes.

Publication of Journal

One of the most important discussions of the Council meeting concerned the publication of a journal or bulletin to inform member associations of the Association's activities and to describe medical practice and professional life in all parts of the world. The first preliminary bulletin will be published during the summer, but in order to decide upon the form and principles of a permanent periodical a special subcommittee was formed, the members being Dr. Charles Hill (Great Britain) as Chairman, Dr. Bauer, Dr. Hugh Clegg (Editor of the *British Medical Journal*), Dr. Morris Fishbein (Editor of the *Journal of the American Medical Association*), and Dr. Yui (Editor of the *Chinese Medical Journal*). The Council also discussed the possibility of holding a conference of editors of the journals of national medical associations in connexion with the meeting of the General Assembly in September.

A little ceremony varied the business proceedings when the Chinese delegate, Dr. Yui, in offering the greetings of the Chinese Medical Association, presented the W.M.A. with some most interesting gifts. These comprised a scroll in illuminated Chinese characters, a "gourd" such as was carried by ancient Chinese doctors as a symbol of their profession; an ivory "medical lady," which was used as a model for the purpose of diagnosis when male doctors were not allowed to examine women patients, and a set of nine porcelain phials used for Chinese drugs. Dr. Yui also presented a scroll to the delegate of each national medical association represented at the meeting.

The bountiful American hospitality pervaded the whole of the meeting. On each of the three evenings members of the Council were entertained to sumptuous banquets, and an afternoon visit was paid to the famous Presbyterian Medical Centre. The United States Committee, the Board of Trustees of the American Medical Association, the New York Medical Society and the New York Academy of Medicine all took part in making the meeting a memorable one for the visiting members of Council.

On the afternoon of April 29 most of the members left for a westward tour to Chicago, Rochester, and Minneapolis, during which they were the guests of the American Medical Association, the Mayo Clinic, and some American universities.

The Home Office announces that Dr. Margaret Philippa Posthumus is no longer authorized under the Dangerous Drugs Acts to be in possession of or to supply dangerous drugs.

Correspondence

North-east Regional Hospital Board Area: Proposed Regional Medical Association

SIR,—Since our letter in the *Supplement* of Feb. 21 (p. 27) the position has materially altered in that the B.M.A. has approached our Essex Association with the request that we initiate the setting up of an interim Regional Consultants and Specialists Committee. We are anxious to assist in any way possible to this end, and a meeting has been arranged at B.M.A. House, Tavistock Square, at 8 p.m. on Friday, June 18, to which all members of the specialist and consultant staffs of hospitals, including tuberculosis dispensaries, in the North-east Metropolitan Regional Hospital Board area are cordially invited.

Agenda.—(1) Election of Chairman. (2) Formation of interim Consultants and Specialists Committee on the lines suggested in the Annual Report of the Council of the B.M.A. (*Supplement*, April 10, para. 60, p. 77). (3) Any other business.

—We are, etc.,

W. L. YELL,
Chairman, Association of Medical Officers
(Essex).

F. N. FOSTER,
Vice-Chairman,
L. S. FRY,
Hon. Secretary.

Chelmsford, Essex.

Christ's College, Cambridge

SIR,—The notes (May 1, p. 111) on the University of Cambridge for the forthcoming meeting contain a list of the colleges with the date of their foundation. From this list there is one notable omission, which filial piety prompts me to supply—i.e., that of Christ's College. Christ's is celebrating at the present time the 500th anniversary of its foundation as God's house, the date of the foundation charter being April 16, 1448. Shortly afterwards, however, Henry VI, needing the site for his great foundation of Kings, made the exchange to the present site of Christ's College, where the north side of the First Court incorporates portions of the buildings of God's house.

When Lady Margaret, deeming herself "heir to all King Henry VI's godly intentions," wished to endow learning, she extended and endowed God's house into her own foundation in 1505, the proctor of that foundation becoming the first Master of Christ's College, whose full title is therefore "Christ's College in the University of Cambridge by Henry the sixth King of England first begun, and after his decease by Margaret, Countess of Richmond, mother of King Henry the seventh, augmented, finished, and stablished."—I am, etc.,

Threlkeld, Cumberland.

G. A. AUDEN.

Mileage Fees for Consultants

SIR,—I hope that the committee concerned with consultant practice under the Act will make sure that the mileage fees are adequate. In a memo recently issued by the Ministry of Health, "agreed following a request from the B.M.A.," 1s. is paid for each mile covered going and coming beyond two miles from one's house. No difference is made for a night call. No provision is made for the time factor, which has a special importance for consultants. Hitherto, when agreeing with the doctor what is a reasonable fee to charge the patient, one has in mind the service rendered, the mileage covered, the time taken, and the time of day.

During the war I was called to Berwick-on-Tweed under the F.M.S. It is 62 miles from my house and the call was after 6 p.m. and I was out of town for 6 hours, mainly at night. I made a diagnosis and did a laparotomy. The fee paid me was purely nominal and I regarded my work as a war service. Under the existing scheme I would have received £6 for motoring 124 miles in the dark and 4 guineas for making a diagnosis and performing a successful laparotomy, a total of £10 4s. for services rendered. I consider working under such conditions as sheer slavery.

In this area we have had for many years an agreement with the leading health authorities concerning maternity work. We are paid 2s. 6d. a mile going and coming from our house (3s. at

night) and receive a more generous, although graded, scale of payments for services rendered. Had my Berwick trip been under our scheme I would have received a mileage fee of £17 1s. and a service charge of 9 guineas, making a total of £26 10s. While I have taken an extreme instance as regarded mileage, the principles apply just the same to the lesser distances and services which consultants are faced with.—I am, etc.,

Newcastle-upon-Tyne.

FARQUHAR MURRAY.

Petrol Rationing

SIR,—It would appear that the position of holders of "E" and "S" coupons in relation to the new "standard ration" requires some clarification. While there may be some justification for withholding the latter from holders of "S" coupons for the time being, there can surely be none whatever in relation to holders of "E" coupons.

I am a doctor and therefore use "E" coupons. During the winter immediately previous to the restoration of basic petrol, and using a 10 h.p. car, I was obliged to ask for, and received, an extra 25 gallons for a four-month period. During the whole period of basic petrol (over two years), and using a 12 h.p. car, I have only had to ask for a total of 30 gallons extra. This means that I have used a considerable proportion of basic petrol for professional purposes during that period. For the six-month period, Oct. 1 to March 31, just expired I was subjected to a cut of 10% (equal to 16 gallons). Before the end of that period (although I had some basic left at the beginning) I was obliged to ask for, and received, a further 25 gallons.

I am now told that I am not entitled to receive any standard ration, but that I am allowed to do up to 90 miles per month of "free" motoring after June 1 on my "E" ration. How can I possibly do this when I am already approximately four gallons a month short of my professional requirements, and when I am told that on no account will any claim for further petrol be entertained? The position is as ridiculous as it is unjust. I am fully aware that you must be getting very many letters of this kind, and that these must of necessity be somewhat personal, but it may be that their very number may lead to some amendment.—I am, etc.,

Abbots Langley, Herts.

F. S. POOLE.

THE LYMPHATIC CONNEXIONS OF THE SUBARACHNOID SPACE

AN EXPERIMENTAL STUDY OF THE DISPERSION OF PARTICULATE MATTER IN THE CEREBROSPINAL FLUID, WITH SPECIAL REFERENCE TO THE PATHOGENESIS OF POLIOMYELITIS

BY

E. J. FIELD, M.D., M.S.

AND

J. B. BRIERLEY,* M.B., Ch.B.

(From the Department of Anatomy, University of Bristol)

There have been suggestions current in the literature from time to time that infective agents (and in particular the virus of poliomyelitis) may extend to the central nervous system along certain ill-defined lymphatic pathways. Yoffey and Drinker (1939) introduced the concept of a combined lymphatic and haematogenous spread, depending on lymphatic absorption from the nasopharynx, and dissemination through the blood stream with the lymphocyte as a virus carrier. However, their experiments were not successful in establishing this mode of spread for poliomyelitis, though it appeared to hold good for the virus of vaccinia (Yoffey and Sullivan, 1939). It is, however, with the elucidation of direct anatomical pathways, particularly those between the spinal subarachnoid space and the abdominal lymphatic system, that the present communication is largely concerned. In the course of this investigation the potentialities of dispersion of fine particulate matter introduced into the cerebrospinal fluid have been observed, and would seem to be not without bearing on the problem of the pathogenesis of poliomyelitis. The principal features of the circulation of the cerebrospinal fluid, as elucidated by the labours of Weed and his co-workers from 1914 onwards, are well known and have been widely accepted. Weed's concept of the formation of the fluid by the choroid plexuses has been broadened to include cortical and spinal blood vessels as formative agencies (Schaltenbrand and Putnam, 1927), and there is now evidence also that a not inconsiderable resorption of fluid takes place into the lymphatic system, not only in the cervical region but also in the lumbosacral zone (Brierley and Field, 1948).

A detailed review of the literature of this problem has been given elsewhere, and only the salient features can be considered here. Schwalbe (1869) and Quincke (1872) both reported the deposition of particulate matter (of unspecified size) in the prevertebral lymph nodes following subarachnoid introduction. The former, moreover, noted in his experiments with dead rabbits that Berlin-blue granules could also pass out from the subarachnoid space extension along the sheath of the optic nerve close behind the eyeball, spread in the episcleral (Tenon's) space, and even pass in along the perivascular spaces of the venae vorticosae to reach the perichoroidal space. Schwalbe was able to demonstrate an excellent filling of lymphatic

plexuses in the nasal mucosa from the cranial subarachnoid space, though Quincke (like Weed many years later) was unable to confirm this. These contradictory results were no doubt due to the difference in size of particles employed, for fine particles (0.5μ) certainly pass with ease from the subarachnoid space into the nasal mucosa. Much of the earlier work on the subarachnoid lymphatic connexions is invalid because of the high injection pressures used, often resulting in obvious tissue damage (cf. Spina, 1900, 1901).

Weed (1914), working with a true solution (iron ammonium citrate and potassium ferrocyanide) as indicator, showed that a small proportion of the cerebrospinal fluid passes into the cervical lymphatic system via the nose, though he did not believe that particulate matter could take this course. He suggested that a similar outflow to the lymphatic system might take place from the spinal subarachnoid space. For this latter suggestion, however, he proffered no experimental evidence, and indeed the technique he used precluded investigation of such an outflow in the lumbosacral region—the very region where it will be shown below to be most marked.

The problem of the spinal subarachnoid connexions was investigated once more by Iwanow (1928), who worked both with living and with dead dogs. He showed that indian ink could make its way from the spinal subarachnoid space to the aortic lymph nodes, but was unable to outline the pathways completely.

Experimental Methods and Results

The animal used was the rabbit, and all experiments were carried out in the living. Under "nembatal" anaesthesia sterile indian ink was introduced into the cranial subarachnoid space or lateral ventricle, precautions being taken to prevent backflow to the surface along the track of the needle. In all cases the amount of indian ink introduced was less than the volume of cerebrospinal fluid withdrawn as a preliminary, and the pressure under which the ink was allowed to run in never exceeded 120 mm. of ink. In order to introduce as large a quantity of ink as possible, more than one instillation was carried out in several animals. In this way it was possible to introduce as much as 4.5 ml. into one animal as opposed to the 0.8 to 1.2 ml. at the single sitting. With this technique there could be no question of any sudden increase in intracranial pressure as a result of the introduction, and conditions within the cranium remained relatively undisturbed. The ink used was

*Holder of a British Medical Association Research Scholarship.

LYMPHATIC CONNEXIONS OF THE SUBARACHNOID SPACE

BRITISH
MEDICAL JOURNAL

made by rubbing down a stick of solid indian ink in physiological saline and filtering the suspension through a No. 5 Whatman filter paper. The size of the particles in the resulting preparation ranged from 0.4 to 1.5 μ , but 90% were about 0.5 μ . The animals recovered from operation in two to two and a half hours and showed no disturbances whatsoever. They were sacrificed at intervals ranging from one to 96 hours after operation. Details of experimental technique have been described elsewhere (Brierley and Field, 1948).

Laminectomy showed that ink reached the caudal end of the spinal arachnoid sac in some seven to nine hours. Where relatively large amounts had been introduced and the animal was allowed to survive for an adequate period the extreme caudal segment was often jet-black. Around the dorsal-root ganglia of the lumbosacral region there were conspicuous accumulations of ink which produced the appearance of two columns of black beads in relation to the dorsal-root ganglia in the cervical region these cuffs of ink around the dorsal-root ganglia were also present, but were not nearly so well marked. In both places ink was also present in relation to the anterior nerve roots. The epidural pads of fat in the lumbosacral region were grey in colour owing to the presence of free indian-ink particles in their interstices (Fig. 1A g). Microscopical

FIG. 1A.—Scheme showing the mode of elimination of indian-ink particles from the subarachnoid cul-de-sac around the dorsal-root ganglion of a spinal nerve. FIG. 1B.—Scheme showing mode of elimination of indian-ink particles from the subarachnoid extensions along the olfactory nerves. Note that in both cases ink particles are eliminated from the subarachnoid space into interstitial tissue and pass secondarily into the lymphatic system. a. Spinal cord, b. Dorsal root ganglion, c. examination of the dorsal-root-ganglion region showed that here ink particles were passing through the covering membranes and coming to lie freely on the surface or passing into the superjacent epidural fat. Whilst many particles were intracellular, many on the other hand were free.

Examination of the abdomen, particularly those around the aortic bifurcation and in the hollow of the sacrum, were filled with ink in degrees varying from pale grey to jet-black. Tiny scattered lymph nodules behind the aorta and inferior vena cava were also filled with ink, and in some favourable cases it was possible to make out under the binocular microscope fine black lines passing backwards towards the spine. Similar small scattered nodules were also found in a corresponding position in the thorax, though only after good filling of the subarachnoid space. In all cases the cervical lymph nodes, both superficial and deep, contained indian ink. In order to determine more fully the channels by which cervical filling took place, indian ink was introduced continuously into the subarachnoid space through a cannula carefully inserted in the lumbar region after laminectomy in the fresh cadaver. In this way under controlled pressure several millilitres of ink could be introduced. Subsequent dissection showed that the ink-bearing afferent vessels of the cervical nodes originate largely from the mucous membrane of the nose. A certain number, however, were found to emerge from the jugular foramen and enter the upper pole of the highest deep cervical node—a fact

noted already by Schwalbe in 1869. As will appear later such vessels deserve consideration in any discussion of possible modes of invasion of the nervous system by an infective agent.

Nasal Outflow.—Histological examination of the whole calcified nose region showed that ink passed down the sheath of the olfactory nerves to reach the connective tissue strands and lymphatic plexus of the nasal mucosa (Fig. 1B). Ink was also present in the endoneurial space to those of Faber (1938). These findings are quite analogous to those of the eyeball revealed in anticipated accumulation of ink in the subarachnoid sleeve of the optic nerve. In addition, however, a diffuse greyness of retrobulbar fat in the vicinity of the nerve was apparent. In order to obviate difficulties arising from the normal occurrence of pigment in this region a series of experiments were undertaken in pure albino animals. Histological examination showed ink particles making their way through the optic-nerve sheath immediately behind the eyeball, spreading out in the episclear space and extending between the fibres of the retractor bulbi muscle. Details of these findings will be published elsewhere.

Passage into the Brain Substance.—In those cases in which ink was instilled directly into the ventricle subsequent examination revealed particles in the depths of the brain substance. Some ependymal cells were seen to be finely stippled with very small granules, and these were also to be found at some depth from the ventricle. Many of these deeper particles had been ingested by phagocytic elements, especially if the animal became detached and move into the subependymal cells migrate. Such passage of indian ink occurred particularly at the inner "angle" of the lateral ventricle as seen in coronal section. To a smaller extent ink particles were also found to have penetrated the wall of the third ventricle. Unfortunately the literature was not examined, but there is evidence in the literature that this is a site at which penetration of particulate matter from the cerebrospinal fluid may take place with relative ease (Hurst, 1930; Hamperl and Heller, 1934).

Discussion

The interpretation of the microscopical appearance of the nerve-root region presents some difficulty and has been discussed fully elsewhere (Brierley and Field, 1948). Briefly it may be stated that transport by phagocytes cannot account entirely for the passage of ink out of the subarachnoid space, a process which must be, in part at least, a passive one dependent upon an actual outflow of cerebrospinal fluid. The arachnoid culs-de-sac around the nerve roots may thus be looked upon as definite points of ex-prevertebral fluid into the lymphatic system and the spinal subarachnoid space.

The rapidity with which indian ink introduced into the cranial division of the subarachnoid space makes its way down to the lumbosacral region is striking. It would seem that particulate matter introduced into any region of the subarachnoid space accumulates in relation to the lumbosacral root ganglia (and to a lesser extent also the lumbar sacral root ganglia) and in the cervical region of the spinal fluid. The arachnoid culs-de-sac around the nerve roots may thus be looked upon as definite points of ex-prevertebral fluid into the lymphatic system and the spinal subarachnoid space.

The arachnoid culs-de-sac around the nerve roots may thus be looked upon as definite points of ex-prevertebral fluid into the lymphatic system and the spinal subarachnoid space.

cases, in addition, fixation by the nervous tissues themselves may play a part in clearing the cerebrospinal fluid.

It is of interest to see how far the results outlined above may facilitate the interpretation of the clinical and experimental findings in poliomyelitis. Furthermore, the possibility of retrograde spread from the periphery to the central nervous system along a lymphatic pathway has been shown to rest on a definite anatomical basis. The experimental accomplishment of such spread by indian-ink particles will be described below.

Two aspects of the poliomyelitis problem may be considered: (1) How far are these findings consonant with the belief that the virus is spread by the cerebrospinal fluid? (2) What pathways are available as channels of access to the cerebrospinal fluid in the first place?

Presence of Virus in the Cerebrospinal Fluid

There are many reports in the literature claiming that the cerebrospinal fluid in human poliomyelitis is not infective. However, it is known that in the experimental animal, following intrathecal introduction of virus, the cerebrospinal fluid remains infective forty-eight hours after inoculation but is no longer so at the sixth day—the time of development of symptoms (Clark and Amoss, 1914). Apparently virus may be eliminated from the cerebrospinal fluid rapidly. Assuming that virus did enter the cerebrospinal fluid from outside the nervous system, its detection would be likely only in the first twenty-four hours or so. With these considerations in view the reports on infectivity of the cerebrospinal fluid were scrutinized with particular reference to the times at which the tests were carried out. Many of the human reports deal with the paralytic stage of the disease—when, presumably, any virus which may have been in the cerebrospinal fluid has long since been eliminated or fixed. Abramson (1917) tested the sediment obtained by spinning fluid from forty cases—“many in the pre-paralytic stage”—with negative results. However, in the absence of more precise information as to time after infection—information which it may be very difficult if at all possible to obtain—the significance of this result is equivocal. So far as the human disease is concerned, therefore, no certain evidence is available as to the infectivity of the fluid at the time when it might be expected to be at its height.

Unfortunately the position is little better for experimental poliomyelitis. The scanty reports available are at variance, and adequate testing of cerebrospinal fluid at the crucial times following par-neural inoculation does not appear to have been carried out. Flexner and Amoss (1914) reported the presence of virus in the cerebrospinal fluid before the onset of the disease. However, they were using the intravenous route, for which the minimum infective dose and the incubation period are greatly increased. On the other hand, Fairbrother and Hurst (1930) made examinations of the cerebrospinal fluid at daily intervals following intracerebral inoculation of virus, and failed to find it in the fluid. These authors are of the opinion that axonic transmission far outweighs cerebrospinal fluid dissemination in importance. There are, however, so many factors which may influence the result of cerebrospinal fluid testing (e.g., time, dose of fluid, strain of virus, susceptibility of test monkey), and the point is of such importance that confirmation of their results is needed. Incidentally it should be noted, as the authors themselves point out, that any intracerebral inoculation is in no small measure also a subarachnoid introduction, since leakage along the needle track cannot be prevented. This fact throws the differences between the results of Clark and Amoss (1914) on the one hand and Fairbrother and Hurst (1930) on the other into still sharper relief.

Leiner and v. Wiesner (1910), in a small series of experiments, found that virus introduced intracerebrally could be readily detected in the cervical, prevertebral, and mesenteric lymph nodes but not in the inguinal group. This suggests that elimination takes place from the subarachnoid space along the same channels as serve for the elimination of particles of indian ink. However, Yofsey and Drinker (1939) found that the virus of poliomyelitis did not pass readily into the cervical lymphatic system following introduction into the nose, and concluded that the particular strain of virus used (Toomey “T”) “did not spread by way of lymphatic vessels and nodes.” Nevertheless, vaccinia virus, the particles of which are of the same order of magnitude as the smallest ink particles in our own experiments, readily utilizes lymphatic channels of spread (Yofsey and Sullivan, 1939). This difference is all the more remarkable since the virus of poliomyelitis is so much smaller (0.003–0.012 μ up to 0.058 μ —Elford, Galloway, and Perdrau, 1935; Levaditi, Kling, Paic, and Haber, 1936) than is that of vaccinia (0.125–0.175 μ —Elford and Andrewes, 1942).

Lesions of the Dorsal-root Ganglia

These lesions are a constant feature of poliomyelitis in human beings (Peabody, Draper, and Dochez, 1912), and may account for the severe pain of root type which is often a feature of the pre-paralytic stage (Russell, 1947). Experimental work suggests that whatever the route by which infection of the nervous system is brought about, such lesions are an early—sometimes the earliest—finding (Flexner and Amoss, 1914). This is what one would expect if the virus were in the cerebrospinal fluid and accumulated at the same outflow points round the nerve roots as does indian ink. Moreover, ink particles may be found in the depths of the dorsal-root ganglia, where many are taken up by the satellite cells. Flexner and Amoss (1914), using varmine particles “smaller than many bacteria,” found the pigment to penetrate the ganglia only with difficulty. The fine ink particles employed by us do so readily, however, and no doubt virus may penetrate with even greater facility.

Distribution of Lesions

Hurst (1932) was of the opinion that the distribution of lesions in experimental poliomyelitis did not follow the pattern in which indian ink or trypan-blue was distributed after introduction in the monkey. Nevertheless, many of Fairbrother and Hurst's (1930) results would seem to be best interpreted on the basis of a cerebrospinal fluid spread of virus. Hurst himself envisages the early involvement of the globus pallidus, hypothalamus, and occasionally the thalamus as possibly due to infection along the perivascular spaces of the anterior perforated substance. Further evidence of invasion from the cerebrospinal fluid was met with in the midbrain and pons. Moreover, the distribution of lesions after infection by intrathecal, intraneural, or intracerebral routes “is essentially the same” (Hurst, 1932). The common factor in distribution would seem to be the cerebrospinal fluid, more especially as neither virus nor lesions are to be found in the areas intervening between widely scattered foci. Furthermore, the various levels of the cord become involved almost simultaneously; and Fairbrother and Hurst (1930), having postulated axonic transmission as the chief mechanism of spread, are forced to the conclusion that “there is an initial delay in the infection of fibres at the site of inoculation, after which the virus travels so rapidly as to reach distant regions of the nervous system as quickly as closely adjacent areas” (p. 40). A simpler working hypothesis would be that of cerebrospinal fluid spread, especially as it is entirely consonant with the observed phenomena. Indeed, the weight of evidence is such that Hurst (1930) himself feels impelled

to allow that "infection of the cerebrospinal fluid contributes to the final picture of fully developed poliomyelitis" (p. 1141).

The experimental results obtained with fine indian-ink particles (in rabbits) suggest that such material in the cerebrospinal fluid has widespread access to the nervous substance. Undoubtedly virus could disseminate in a similar manner, and this together with invasion from the superficial subarachnoid space along perivascular channels may account for the early lesions of poliomyelitis in loci accessible to cerebrospinal fluid.

The interesting results of Jungeblut and Spring (1930) require consideration. They found that intracerebral inoculation of virus in a monkey whose cord had been previously transected resulted in an attack of poliomyelitis, and although the distal segment of cord was freely bathed in cerebrospinal fluid neither virus nor lesions could be found in it. Howe and Bodian (1941) repeated and extended the work of Jungeblut and Spring, and found that even after careful section of the spinal cord and obliteration of the subarachnoid space (checked by indian ink and methylene-blue injection at necropsy) virus could pass down to the isolated lumbar cord in one case out of four after intranasal or intracerebral inoculation. (The technique in this one positive case, however, was such as to render the significance of the result equivocal.) On the other hand, inoculation of the sciatic nerve in animals with completely divided cord and subarachnoid space resulted in progression of virus into the upper-cord segment in two out of four cases—"possibly along the paravertebral sympathetic chains." However, further experiments showed that even after bilateral sympathectomy of two or three ganglia at the level of cord section had been carried out, inoculation direct into the lumbar cord resulted in progression of virus to the upper segment of nervous system in every case. The authors suggest that virus passed from the spinal cord to the wall of the gut via sympathetic-nerve fibres and thence to the brain-stem along the vagus nerve. An alternative and simpler interpretation will be considered below after further experimental results of our own have been described.

Channels of Access of Virus to the Cerebrospinal Fluid

The nasopharynx, tonsil, and upper respiratory tract have all been implicated from time to time as portals of entry for virus both in the human and in the experimental animal. Our own results have substantiated the existence of a definite anatomical pathway (in the rabbit) between the cranial subarachnoid space and the deep cervical lymph nodes by means of lymphatics which emerge through the jugular foramen. Since the tonsil, too, is connected with these nodes, the anatomical basis exists for lymphatic extension of virus from tonsil to cranial subarachnoid space. This connexion is in addition to the well-known and more readily demonstrable paths from the nasal mucosa.

In recent years much attention has been given to the gut as a portal of entry, largely from the standpoint of axonic transit of virus. Although there is a wealth of pathological evidence to suggest that the lymphoid tissue of the bowel is the site of early and often severe lesions (Wickman, 1913; Burrows, 1931; and many others), no serious attempt seems to have been made to examine systematically the possibility of a retrograde lymphatic spread of virus to the spinal cord from the bowel. In view of the definite connexions which have been shown to exist between the spinal subarachnoid space and the abdominal lymphatic system the possibility of bringing about experimentally retrograde spread of ink particles from the mesenteric and prevertebral lymph nodes to the cord was explored.

Retrograde Lymphatic Flow to the Cord: Experimental Methods and Results

In order to produce a stasis of the abdominal lymphatic drainage, a condition favourable to the retrograde flow of ink, ligation of the thoracic duct was performed. Because of the multiple lymphatico-venous communications existing within the lumbar region of many lower animals, the stasis resulting from such an operation is incomplete. The ligation was performed in the mid-chest region by a right transpleural approach, respiration being maintained mechanically throughout the experiment. Laparotomy was then performed and indian ink, made up in reconstituted plasma, injected into the aortic and mesenteric lymph node. By repetition of this procedure at two- to three-hour intervals up to 4 or 5 ml. of ink could be introduced. Animals have survived these formidable operative procedures for periods up to twelve hours, during which time the pulse has been good and repeated doses of nembutal have been needed to prevent recovery of consciousness.

By this technique it has been possible to trace fine lymphatic channels backwards from the region of the cisterna chyli, usually through one or more tiny prevertebral nodes, round the side of the vertebral column. To such vessels come tributaries which collect lymph from the dorsal-root-ganglion region, and in particularly successful fillings of these minute vessels ink is to be found right on the dorsal-root ganglion itself and the adjacent cord membranes. Ink may even spread further back in the main lymphatic vessel and pass into the substance of the erector spinae musculature. A detailed account of these anatomical pathways (Field and Brierley, 1948) is not necessary here, but they may be summed up as follows. Lymphatic vessels in the substance of the erector spinae muscle unite to form one or more vessels which accompany the nerve and blood supply of the muscle towards the intervertebral foramen. Here lymph-vessel branches come in from the dorsal-root ganglion and its related epidural fat, and the main vessel then continues ventrally round the side of the spine, to reach the cisterna chyli or one of the many subsidiary longitudinal ducts which empty into it. As a rule a small lymphatic nodule is interposed in the course of the vessel on the anterolateral aspect of the spine (Fig. 2).

It would seem, then, that under certain experimental (and admittedly highly artificial) conditions there is the possibility of a retrograde flow of fine particulate matter from the mesenteric and prevertebral nodes to the spinal cord. Conditions approximating those of the experiments out-

FIG. 2.—Scheme indicating the disposition of the lymphatic drainage of the nerve root: a. Lymphatic arising in the posterior spinal musculature; b. Small lymphatic tributaries from dorsal-root-ganglion region; c. Lymphatic channel passing ventrally round vertebral body under cover of psoas muscle; d. "Segmental" vessel visible from the abdomen; e. Small prevertebral lymph node; f. Longitudinal collecting channel on front of spine.

lined above might come about in man or monkey should a temporary functional occlusion of the thoracic duct leading to lymphatic stasis take place.

Unfortunately, little is known of the responses of the thoracic duct to physio-pathological stimuli, though the presence of plain muscle fibres and nerves in its wall suggests that variations in calibre do take place. Spasm of larger lymphatic channels is a phenomenon well recognized by experimental workers, and often arises, it is said, as the result of drying or unnecessary handling. This problem is receiving further attention.

It is of interest to recall that severe muscular exercise or bowel contraction results in a considerable increase in lymph flow from the parts concerned and a steep rise in pressure in the larger collecting channels (Drinker and Yoffey, 1941). These circumstances, together with a partial obstruction of the thoracic duct—perhaps at the aortic opening in the diaphragm—might succeed in creating a temporary diversion of lymph towards the spinal cord. It should be recalled in this connexion that the small "segmental" vessels which pass ventrally round the sides of the spine are not valved. Such a retrograde lymphatic invasion of the nervous system would also account for the early presence of lesions in the dorsal-root ganglia of the lumbar region. However, it must be realized that virus which gained access to the subarachnoid space by whatever route would also accumulate in this region (see above). Probably the same route of access does not hold for all cases.

The lymphatic vascular system related to the dorsal-root ganglia must be taken into account in evaluating the important results obtained by Howe and Bodian (1941) referred to above. These authors mention the possibility of lymphatic spread of virus but pass it over in favour of axonic dissemination along "some unusual nervous connexions." Our own results would seem to furnish a relatively simple lymphatic anatomical pathway by which virus might spread from an isolated lumbar segment of cord to the rest of the nervous system. Injection into the lumbar cord is virtually a lymphatic injection, assuming that virus may take a path readily available to fine indian-ink particles. The virus which leaves the lumbar sac by lymphatics from the dorsal-root ganglia may then readily pass upwards (the normal direction of flow) and subsequently in a retrograde manner to dorsal-root ganglia above the site of section. To us—unwedded as we are to the concept of axonic transmission—this seems a simpler explanation and one deserving of experimental testing. Furthermore, experiments by one of us (J.B.B.) have shown that injection of indian ink "into" the sciatic nerve will often lead to a beautiful filling of the lymph nodes around the bifurcation of the aorta. From these the injection mass may pass to the paravertebral lymphatic channels. It is not, therefore, surprising that infection of the upper segment of cord should have occurred in Howe and Bodian's elegant experiments following inoculation of the sciatic nerve with virus.

Summary of Conclusions

1. Particulate matter in the cerebrospinal fluid is rapidly removed and tends to accumulate at outflow points round the lumbar and cervical nerve roots.
2. The prevertebral lymph nodes are the "regional" nodes of the spinal subarachnoid space.
3. The presence of virus in the cerebrospinal fluid in both human and experimental poliomyelitis would seem to be uncommon. However, in view of the rapidity with which particulate matter has been shown to be eliminated from the subarachnoid space, it is probable that reports in the literature are concerned with stages when any virus which may have been present earlier has already been eliminated.

4. The distribution of fine particulate matter in the cerebrospinal fluid has been compared with that of the early lesions of poliomyelitis, and certain similarities have been noted suggesting that the fluid may play a more important part in the pathogenesis of the condition than that usually accorded it by the adherents of the theory of neuronic transmission.

5. The anatomical basis for invasion of the nervous system along direct lymphatic communications has been described. Lymphatics emerging through the jugular foramen end in deep cervical lymph nodes which also drain the tonsil and nasopharyngeal region. The lymphatic connexions of the cranial subarachnoid space via the neurovascular foramina are in addition to the well-known connexion via the sheaths of the olfactory nerves and the nasal mucosa.

In relation to the spinal subarachnoid space a system of valveless lymphatic channels has been described. They are summarized in Fig. 2. Lymphatic vessels start in the substance of the post-spinal musculature, and pass ventrally in company with the nerve and blood supply of the muscle towards the neighbourhood of the intervertebral foramen. Here fine tributaries reach the lymphatic from the neighbourhood of the dorsal-root ganglia and arachnoid sac around the nerve roots. Having received these, the lymphatic continues around the side of the vertebral body to end in one of the several valveless longitudinal trunks on the front of the spine.

This lymphatic pathway has been filled experimentally with indian ink in a retrograde manner from the mesenteric and prevertebral lymph nodes, after preliminary ligation of the thoracic duct in the thorax. Whilst great caution must, of course, be exercised in carrying over results obtained in the rabbit to man and monkey, the possibility of a similar retrograde passage of virus to the lumbar region of the cord must be maintained.

6. Certain recent results in experimental poliomyelitis have been discussed in the light of the lymphatic connexions set out in this communication.

It is a pleasure to record our indebtedness to Professor J. M. Yoffey for his never-failing interest and encouragement, and for his expert advice on general problems of technical procedure appertaining to lymphatics.

EPIDEMIOLOGY OF THE 1947 OUTBREAK OF POLIOMYELITIS IN ECCLES*

BY

W. P. SWEETNAM, M.B., Ch.B., D.P.H.

Assistant Medical Officer of Health, Lancashire County Council; Deputy Medical Officer of Health, Borough of Eccles

Eccles covers an area of about 3,500 acres; its southern boundary is formed by the Manchester Ship Canal. Irlam Urban District lies to the west; Worsley and Swinton Urban Districts to the north, and Salford County Borough to the east. One-half of the borough consists of reclaimed peat land, unsuitable for building. The other half, in which all but one of the cases occurred, is completely "built up."

This portion of the borough is bisected from north to south by the Bridgewater Canal and is quartered by the intersection of two main arterial roads. The estimated population in June, 1947, was 41,940, living in 12,717 structurally separate dwellings. Practically the whole of the population falls into the Registrar-General's three lower social grades. The infant mortality rate in 1947 was 45.5. The borough is a typical Lancashire working-class urban district.

The method of field study followed broadly the usual pattern of inquiry into cases of infectious disease, being rather more extensive and detailed than usual. A visit was made to the household immediately on notification; and details of dates of onset, list of members of the household, giving ages, occupation, and places of work, and particulars of any recent illnesses, were recorded on a standard form. Any known direct or indirect contact was noted, also visits and visitors. Details and sources of foodstuffs, especially milk, ice-cream, and fruit, were noted, together with usual inquiries about numbers of rooms, sanitary arrangements, and the presence of domestic animals, flies, and vermin. Further information received from outside sources usually necessitated other visits to a household; it was often found that useful additional information could be obtained at these later visits, when people had had an opportunity to think about the questions previously asked.

In all, 58 cases and 200 contacts were investigated in this manner: 46 cases and 180 contacts in Eccles and 12 cases and 20 contacts in the neighbouring district of Irlam—these latter in connexion with the origin of the outbreak in Eccles.

General Epidemiological Findings

Between July 4 and Nov. 1, 46 notifications were received. The first case occurred on June 18, the date of onset of the last was Oct. 25. A graph of the weekly incidence of cases shows a slow rise in the third week of June, a more pronounced rise in the middle weeks of July, a peak, explosive in type, in the week of July 27 to Aug. 2, followed by an initial rapid decline and a slower tapering off. At first sight the explosive type of curve suggests a disease of short incubation period and high infectivity in a susceptible population—an impression that is not substantiated on closer examination of the epidemiological findings.

The attack rate and age distribution are shown in Table I. It will be seen that the brunt of the infection fell upon pre-school children (61% of total). There was only one case in a child under 1. The eldest of the series was a man aged 26. The attack rate, 1.09 per 1,000, is very high—the highest to occur in any local government district during this epidemic. There were three fatal cases, giving a case

mortality of 6.5%. The sex incidence was 63% male, 37% female. In considering these figures it must be emphasized that the overall number of cases is small.

Graph showing weekly incidence of cases.

TABLE I.—Attack Rate and Age Distribution

	Age Groups in Years				
	0-4	5-9	10-14	15+	Total
No. of cases	28	11	3	4	46
Percentage	61	25	7	10	100
Attack rate per 1,000	8.07	3.85	1.14	0.12	1.09

Incubation Period

Estimations of the incubation period have varied widely; the figures given in textbooks range from six to twelve days. It was found difficult to estimate an incubation period. To do this accurately it was thought necessary to establish a single exposure of limited duration. In only one instance was there a direct case-to-case contact; again, there was only one instance of two cases in one household, these two cases occurring within two days of each other and both probably infected from a common source. These limitations, combined with the fact that the outbreak occurred in an open populous community, largely accounts for this difficulty. In five of the early cases the criteria of a single exposure of limited duration were satisfied.

Case 1.—It was established that this patient, the first case in Eccles, had been visited by a cousin from Irlam. The visiting child lived in a part of Irlam where a small group of cases had occurred. The visiting child herself developed a sore throat, general malaise, and a temperature for 24 hours, and the following day visited the Eccles child. These two children were on affectionate terms, and kissed each other. Nine days after the visit the Eccles child developed poliomyelitis.

Case 2.—This child, aged 4, lived in an area up to then free from infection, and had only once been away from the immediate neighbourhood of its home for over a month. It was taken to visit a grandmother in an area where three cases had already occurred. During this visit the child was nursed by the sister of a previous case who herself developed an abort attack next day. The child developed poliomyelitis nine days after the visit.

Case 3.—This is the only example of a case-to-case contact. A girl and a boy, aged 11 and 12 respectively, both star collectors, exchanged stamps, during which the usual licking stamp hinges took place. The boy became ill the same evening and the girl 13 days later. For most of these 13 days they had been away in Anglesey on holiday and no other contact could be established.

Case 4.—The patient, an adult male, played cards with father of two children who had previously contracted poliomyelitis within two days of one another. The cards used were and the players licked their fingers. The man became ill exactly a week later. An interesting feature of this case was that the man had a short febrile illness for the 48 hours following card game; this "illness of infection" is known to occur with

*The basis of a paper given to the North Western Branch of the Society of Medical Officers of Health, Manchester, Nov. 14, 1947.

one or two days of exposure (McFarlan, Dick, and Seddon, 1946). He recovered completely, returned to his work as a manual labourer, and became ill again with typical symptoms of onset five days later—that is, seven days after contact.

Case 5.—This patient, a child of 15 months, the second case to occur on the eastern side of the borough, had been away on holiday on a farm in North Wales and returned on July 18. It became ill on July 27 and must have become infected during these nine days. The family consisted of the child and mother only. On the day after the return from holiday, July 19, the child was taken to the western side of the borough to visit relatives living within a few doors of a previous case and contacts of that case, and became ill eight days later.

These five instances give incubation periods of 7 days, 3 days, two of 9 days, and 13 days.

Course of the Outbreak

Notifications in Irlam were maximal during the weeks of June 7 to 21; in Eccles in the week ending Aug. 2; in Salford, immediately to the east, during the week ending

was ill at home the mother did not leave the house and the father was working overtime on the west side of the borough; these circumstances probably account for the lack of an early spread from this focus. The case marked with a hollow cross was a fatal case that was never notified, but one from which it was possible to assess an incubation period (Case 1).

Map 2 shows the distribution of the 14 cases which began during the week of maximum incidence, July 27 to Aug. 2. These are widely scattered throughout the borough.

Map 3 shows the distribution of the 18 cases which occurred between Aug. 3 and Oct. 25, the date of onset of the last case. These cases tend to lie on the eastward side of the borough.

Map 4 is a composite map showing the distribution of all cases throughout the whole period. There is a tendency for cases to lie in close proximity to the main roads. Over one-half lie either on or within 50 yards of a main road, and three-quarters within 100 yards of a main road. There is some suggestion of grouping of cases. A closer examination of dates of onset reveals some centrifugal spread in two or three areas.

The whole of this area, only a mile and a half square, is densely populated. The outbreak was confined to the

MAP 1.—Distribution of Cases with onset June 18 to July 26.
— Main roads. — Canals.

MAP 3.—Cases with onset Aug. 3 to Oct. 25.

MAP 2.—Cases with onset July 27 to Aug. 2.

MAP 4.—Showing distribution of the whole series of cases.

Aug. 9; and in Manchester, further east again, during the week ending Aug. 30. There seems to have been a marked spread from west to east as is shown in Maps 1, 2, and 3.

Map 1 shows the distribution of the 13 cases which started during the six weeks up to July 26. All these, except one, are on the westward side of the Bridgewater Canal. The exception was a case in which it was possible to assess an incubation period (Case 2). The family consisted of one child (the patient) and the mother and father. During the week when the child

western half of the area for nearly six weeks, and it seems that the Bridgewater Canal may have formed a barrier. This may seem to be far-fetched, but on closer examination it can be seen that communication between the two portions of the borough is restricted to three bridges, of which the lower one is rarely used by pedestrians. Each portion of the borough tends to have its own employment and amusement facilities and its own shopping centres.

Mode of Spread (Human)

Contacts

A history of direct or indirect contact with a previous case within a fortnight of onset was obtained in 20% of cases. If one adds visits of the patient or a member of the household from an area previously free from infection to an immediate locality where cases had already occurred the proportion is raised to 33%. The addition of instances where contact had almost certainly occurred, although not admitted, raises this proportion to 46%.

It was very striking how often during the first half of the outbreak indirect contact between cases could be established and, in contrast, how very rarely during the latter half.

During the same periods direct contacts alone had increased from about 50 to over 200; indirect contacts increased by a far bigger proportion, and were very widely scattered throughout the whole borough. Opportunities for indirect contact must have been very numerous during the latter half of the outbreak and correspondingly difficult to establish with certainty. Indeed, with opportunities for contact so great it is difficult to explain the escape of so many children. This proportion of indirect contacts suggests a carrier wave preceding the actual cases of paralysis.

The Abortive (Non-paralytic) Cases

An increasing interest has been taken in these cases in recent years. They are known to excrete the virus from the nasopharynx (Paul and Trask, 1932) and in the stool (Horstmann *et al.*, 1944, 1946). During the Eccles outbreak any short non-specific illness characterized by malaise, sore throat, headache, with or without backache or neck stiffness and not progressing to paralysis, was regarded as an abortive illness. There appeared to be no advantage, in an epidemiological investigation, in adopting the further clinical subdivision of such illnesses into abortive and non-paralytic forms. These symptoms could normally be indicative of many common respiratory infections but for the important fact that they occurred during an epidemic of poliomyelitis and also during a hot dry summer when respiratory infections would be least expected.

The data concerning abortive cases are unsatisfactory since they are largely based on a history of illness in contacts occurring at about the same time as the illness of the frank case. There were, however, 15 such instances of abortive poliomyelitis. This figure is almost certainly too low. Five of these cases were probably responsible for infecting persons who developed frank paralytic attacks of poliomyelitis.

In an attempt to assess more accurately the prevalence of abortive cases a survey of two areas of the borough during the outbreak was made (Table II). In these two

TABLE II.—Prevalence of Abortive Cases in the Immediate Neighbourhood of a Frank Case

Area	No. of Houses	Population		Frank Cases		Abortive Cases	
		0-15	Over 15	0-15	Over 15	0-15	Over 15
A	50	51	110	1	0	15	1
B	50	41	93	0	0	3	2

areas the housing conditions and social status of the inhabitants were comparable. Each area contained a small communal children's playground. In Area "A" a frank case of poliomyelitis had occurred. In Area "B" no cases had been notified. A house-to-house census of 50 houses in each area was undertaken and careful inquiries made of any illnesses during the months of July, August, September, and October. Two visits to each household, one at the

beginning of the outbreak and another at the end, were made. Each householder was asked to keep a careful record of all minor illnesses, and all school absentees living in these two areas were investigated. Area "A," in which the frank case occurred, contained 110 adults and 51 children under 15. In this area one adult and 15 children gave histories of illnesses compatible with a diagnosis of abortive poliomyelitis. These 16 cases occurred in two distinct foci—12 in adjacent households surrounding the house in which the frank case occurred, and four at the other end of this area but also in adjacent houses. Area "B" contained 93 adults and 41 children under 15. In this area two adults and three children gave histories suggestive of abortive illnesses (Table II). These five cases were widely dispersed throughout this area.

The high proportion of abortive to frank cases is borne out by inquiries made of general practitioners in the borough, several of whom estimated that in their private practices they saw between 10 and 20 abortive cases to one frank case.

Carriers

Carriers are known to excrete the virus for the same period as frank cases (Rhodes, 1947). The Eccles outbreak started with four cases practically simultaneously. The first (Case 1) was infected by a cousin from Irlam (an abortive case). The other three were probably infected by healthy carriers, household contacts of these cases being workmates of direct contacts of Irlam cases. Several later cases (including Cases 4 and 5) were also probably infected by healthy carriers.

Mode of Spread (Non-human)

The restriction of infection to the westward side of a canal less than 25 feet wide for 38 days, the geographical distribution of cases, together with other convincing epidemiological evidence, indicated that water, milk, other foods, rodents, domestic animals, flies, and railways played no significant part in the spread of infection.

Discussion

Age Distribution.—The corrected notifications for England and Wales for 1947 show that only 31% of cases occurred in the 0-4 age group (Registrar-General, 1947) compared with 61% in Eccles. Judging by the findings of observers in other countries the factors which probably account for the lower age distribution in Eccles are (1) the early onset of the epidemic (the last case occurred on Oct. 25, at which time cases were still being notified in England and Wales at the rate of over 250 a week); and (2) the high population density. The inhabited portion of the borough has a density of over 30 persons per acre.

Mode of Spread.—Factors which strongly indicated that in Eccles, human contact played the major part in the spread of infection were: (1) evidence of carrier-to-case contact and contact between abortive and frank cases; (2) evidence of numerous abortive cases, especially in close proximity to frank cases; (3) a marked tendency for cases to lie on or in the immediate neighbourhood of main roads; (4) some suggestion of grouping of cases and centrifugal spread; (5) an initial marked restriction of the spread of infection by the Bridgewater Canal, where communications between the two halves of the borough are restricted; (6) a rapid spread once that barrier was crossed; (7) the exclusion of other important means of spread.

Sources of Infection.—The virus has been recovered from the pharynx of patients (Howe *et al.*, 1944) and contact (Flexner *et al.*, 1913), from the faeces of cases (Pearse and Rendtorff, 1945) and contacts (Pearson *et al.*, 1945). Space does not permit a discussion of the

relative importance of these two sources of the virus. In the few instances during this outbreak where there was evidence of the prolonged or intimate personal contact usually associated with faeces-spread diseases, the circumstances strongly suggested a nasopharyngeal spread of infection. Five of such instances are described in connexion with the incubation period.

Preventive Measures

The experience in Eccles was that schools played no significant part in the spread of infection. Two-thirds of the total cases and one-half of the cases among school-children occurred during the time the schools were closed for the summer holidays. No infection could be traced to school contact.

Notification should include abortive or non-paralytic cases. It has already been noted that these cases are many times more prevalent than the frank paralytic cases, are known to be infectious, are rarely recognized as such, and play a major part in the spread of infection—certainly a much more important part than the frank paralytic case in hospital.

It would be an advantage if the present regulation requiring the separate notification of polio-encephalitis and poliomyelitis was superseded by one reverting to the more accurate and comprehensive term of polio-encephalomyelitis, with perhaps a further subdivision into paralytic and non-paralytic or abortive cases. This would encourage more frequent and earlier notification and greatly assist the medical officer of health or those responsible for control and prevention.

As over two-thirds of the cases in England and Wales occurred in persons over the age of 5 the term "infantile paralysis" must now be regarded as a misnomer.

The isolation period usually recommended is three weeks (Memo. to Ministry of Health, 1947). In view of the findings of Horstmann *et al.* (1944, 1946) that 50% of patients are still excreting the virus in the stools between the third and the fourth week, this period is theoretically too short. The collected findings of Brown *et al.* (1948) that 20% of family contacts excrete the virus would indicate that isolation measures should, ideally, include the whole family.

Viewing in retrospect the wide distribution of cases (Map 4) and the high attack rate (Table I) one cannot help feeling critical of the efficacy of the accepted preventive measures. It must be realized, however, that although these measures are not likely to stop an epidemic they will certainly slow down its spread. Since epidemics nearly always abate with the onset of cold weather; this "slowing down" may be expected to result in a large number of susceptible persons remaining untouched who would otherwise become permanent cripples.

Summary

During the 1947 poliomyelitis epidemic the borough of Eccles suffered the highest attack rate of any local authority district. There were 46 cases, giving an attack rate of 1.09 per 1,000 of the population. The case mortality was 6.5%.

The incubation period was 7 to 13 days. Only one family had more than one frank case. There was only one instance of a frank case-to-case contact.

The epidemic was confined for nearly six weeks to the western half of the borough by a canal which restricted communications between the two halves.

The results of field studies indicated that the chief factor in the spread of infection was human contact, in which abortive cases and healthy carriers played the major part. The presence of the virus in the nasopharynx of patients and carriers was of much more importance for the spread of infection than was its presence in faeces.

A survey undertaken revealed the presence of numerous abortive cases, especially in close proximity to frank cases, and suggested that of every 20 persons who showed clinical signs and symptoms of infection less than one developed into a frank paralytic case.

Suggestions to improve the present system of notification are made, particularly the necessity for notifying abortive cases.

I am indebted to Dr. J. E. Spence, M.O.H. to the Borough of Eccles, for his invaluable encouragement and advice, and to members of his staff for assistance in the field work and in the preparation of the charts.

THE ECOLOGY OF POLIOMYELITIS IN A MILITARY CAMP IN 1947

BY

G. JOLY DIXON, M.A., M.D., M.R.C.P.

Lieutenant-Colonel, R.A.M.C.: Officer in Charge, Medical
 Division, Military Hospital, Catterick Camp, Yorkshire

The widely held view that cases of overt poliomyelitis are to be regarded as the severer examples of a carrier epidemic makes the recognition of early non-paralytic cases of special importance (Memo. by M.O.s to Ministry of Health, 1947).

This paper is concerned with the search for such a carrier epidemic at Catterick Camp, where paralytic cases occurred during the 1947 epidemic. The population at risk can be broadly classified as follows: 13,500 to 14,500 young soldiers under training living in huts each containing 20 beds, and 3,540 inhabitants of 1,169 Army quarters—1,785 adults, 1,612 children under 15, and 143 children over 15.

Towards the end of June a case of poliomyelitis in the pre-paralytic state was isolated in the Military Hospital, and two other patients who did not develop paralysis were similarly treated because of meningism. After receiving information about another paralytic case in a near-by camp instructions were issued to admit all suspicious cases to hospital. This procedure resulted in the admission of eight paralytic cases, including a fatal one, ten probably abortive cases, and eight suspects. The paralytic cases included five young soldiers and one child from the camp area; four of these became ill between Aug. 2 and 26, one in June, and one in October.

Symptomatology of Paralytic Cases

An acute onset with headache, stiffness and pain in the back, occasional vomiting, and twitching of the muscle groups which later became paralysed was the rule. However, five of the eight paralytic cases had been slightly indisposed for about a week; only one had sought advice, and he had felt well enough to go on leave hitch-hiking the day before he was finally taken ill (Table I).

Objectively the early cases presented with pyrexia ranging from 101 to 102° F. (38.3 to 38.9° C.), slight drowsiness,

and furred tongue. The most characteristic sign was stiffness of the back, especially pronounced in the lumbar and dorsal spine, where the immobility was almost complete, making the body rigid like a plaster cast. Limitation of neck flexion prevented the chin being flexed more than half-way to the chest wall; Kernig's sign was present after flexion of 45 degrees. The combination of these factors made it impossible for the patients to sit up in bed. Elicitation of these signs usually produced pain in the back in either the mid-dorsal or the lumbar region. The skeletal muscles were often tender on palpation, and localized pains occurred in the regions later paralysed. The pyrexia became remittent with maximal temperatures varying between 100.8 and 102° F. (38.2 and 39.1° C.) and lasting three to six days. Only one case developed anything resembling "dromedary" pyrexia observed in certain other epidemics (McFarlan, Dick, and Seddon, 1946). This child (Case P5) had fever of 102° F. (38.9° C.) for three days and meningism, then after two symptom-free days developed a minor palsy of one leg with recrudescence of pyrexia to 99° F. (37.2° C.).

Six of the eight paralytic cases were treated at complete rest in bed within a few hours of developing acute symptoms. The early history of the fatal case (D1) is more obscure, but it is possible that he delayed reporting sick for a week. The palsy in the seven surviving paralytic cases occurred towards the end of the feverish period, between two and four days after the onset of acute symptoms. In only two cases was this palsy mild enough to leave any hope of recovery. This finding is in sad contrast with those of Ritchie Russell (1947) in a much larger series. He divided his cases into those in which palsy was mild enough to allow hope of full recovery and those in which residual impairment of function was to be expected, and observed that 18 of the first group had had rest in bed within 24 hours of the development of acute symptoms and 19 of the second had not had this advantage; the reverse had occurred in only three and two patients respectively. It could be suggested that, as he examined convalescents, many mild cases that did not take to bed had escaped his notice.

The cerebrospinal fluid in the five paralytic cases examined showed a pleocytosis ranging from 26 to 260 cells

per c.mm., the cells being chiefly lymphocytes. The protein content of the fluid varied from 40 to 95 mg. per 100 ml. (Table I).

Differential Diagnosis

It is important to stress that before the development of the palsy poliomyelitis can only be suspected. A further group of 16 patients from the camp so resembled the paralytics in their earlier stages that they were suspected of being cases of poliomyelitis. In eight of these the discovery of other disease, presumably adequate to account for the symptoms and signs, probably refuted the diagnosis of poliomyelitis. Only two of them had abnormal cerebrospinal fluid; both fell ill in the month of June, and the remainder in September and October. It seems probable that, as Warin (1947) postulated for Leeds, the known occurrence of poliomyelitis influenced the diagnosis in later cases.

Presumed Abortive Cases

Ten of the suspected cases never developed sufficient signs or symptoms to warrant an unequivocal diagnosis. Their main interest lies in the fact that six of them occurred in Catterick Camp between July 23 and Aug. 28 and coincided with the paralytic cases. Their illnesses were characterized by backache, headache, stiffness in the neck and fever. In two meningism occurred; three vomited and another two developed doubtful paresis of short duration. In six of these patients subjected to lumbar puncture the cerebrospinal fluid was found to be abnormal (see Table II).

The clinical findings in these 10 patients are similar to those labelled non-paralytic poliomyelitis by Casey, Feinstein, Abrams, and Bundesen (1946) among 14 children who became ill five to 25 days after being in contact with the same febrile case of poliomyelitis. Andelman, Fishbein, Casey, and Bundesen (1946) at the same time examined the cerebrospinal fluid of 19 contacts suspected of suffering from subclinical poliomyelitis and found the protein content to be above 45 mg. per 100 ml. in 79%, as against a similar finding in only 10% of 10 non-contact controls. Children who had suffered a febrile illness not thought to be due to the virus of poliomyelitis.

TABLE II.—Cases of Short Fever resembling Initial Stages of Poliomyelitis

A8		19	3	21/8	22/8														103	3	2	45	4	Knee-jerks absent at one examina- tion only
A9		18	1	24/8	25/8														100 S	1				Vertigo and photophobia
A10		15	9	20/9	21/9	1	9												100	2	1	60	16	

Cases A1 and A10 came from near-by units. Case A2: A married corporal living in quarters in camp. Case A5: Cerebrospinal fluid contained 440 red blood cells per c.mm.

Epidemiology

No evidence of contact between any of the paralytic cases in Catterick was found, and no two cases came from the same unit. In one instance a presumed abortive case (A5) used the same wash-place as a paralytic patient (P4) and sickened 10 days after the latter was removed to hospital; a 13-day interval was also observed between two abortive cases (A2 and A3) belonging to the same regiment who were probably not in contact.

No infection of the nursing personnel attending the cases was observed. Most of these nurses were young male orderlies of the same age group as the patients, and no masks were worn. In view of McAlpine's (1945) report of fatal poliomyelitis in two nursing sisters attending cases in India, more precautions might have been advisable. One member of the hospital staff, a clerk aged 19 (Case A4), became ill with presumed abortive poliomyelitis, but his only contact with a case or suspected case occurred four or five hours before he developed acute symptoms.

Up to the middle of August the paralytic cases and suspected non-paralytic cases occurred singly or in pairs at intervals of approximately nine to 14 days (see Graph):

Graph showing dates of onset of cases. P=Paralytic poliomyelitis. A=Presumed abortive poliomyelitis.

later this pattern was lost. This type of case-spacing is described by Casey, Fishbein, Abrams, and Bundesen (1946), who postulate carrier waves in which only 2% of the cases develop paralysis, the waves being due to an incubation period of six to 14 days as observed by Casey (1942) and Aycock and Kessel (1943).

Search made for such carrier waves by examination of sick reports and admissions suggested that the diagnoses of tonsillitis, pharyngitis, coryza, and short fever were applied to different clinical manifestations of the same infection, as several of these conditions were often recorded simultaneously in the same unit, which would later be free of similar cases for some weeks. During the period June to October the weekly incidence of the aggregate of these diseases in the camp was between 0.07 and 1.1 cases per 1,000, which is not greater than in previous years. Twenty-four of these cases were thought to be serious enough for admission to hospital as opposed to the Camp reception

station, and from the throats of 17 of these β -haemolytic streptococci were cultured.

There were some ten large units of over a thousand men in the camp. One of these, which had furnished a case of paralytic poliomyelitis, produced only two instances of minor fever, and these at an interval of over three months from the case of poliomyelitis. Another similar unit, which had the highest incidence of minor fevers and actually also had the highest weekly record in the camp—namely, 4.5 per 1,000—also had one case of paralytic poliomyelitis. In other units producing paralytic cases the incidence of minor fevers was between these extremes, and two large units with relatively high instances of minor fever had no cases of poliomyelitis and no suspected cases.

Thus it would appear that these minor fevers were not related to the transmission of poliomyelitis. But as five of the paralytic patients were indisposed for a week before finding it necessary to seek medical advice it is possible that similar cases of indisposition were widespread and unrecognized; or, alternatively as postulated by McFarlan, Dick, and Seddon (1946), apparently healthy males can act as carriers of the epidemic.

Only one case (P5) and no suspected case occurred among the 1,612 children in the camp area. Preliminary reports of the English epidemic of 1947 (McAlpine, 1947) suggest that approximately 20% of notifications have been of patients over 15 years of age; even so, the disproportion is probably significant.

Three of the young soldiers developing paralytic poliomyelitis came from professional or middle-class families and two were from superior artisan families. Bernstein, Clark, and Tunbridge (1945), observing the same phenomenon among Service personnel in Malta, postulated that these classes had been more sheltered from the virus of poliomyelitis in their youth and hence were more susceptible. The young soldiers in Catterick were certainly in closer contact as a group and had more outside contacts than the children.

It may be stated that during the period June to October there were extremely few flies or other insects in the camp. The sanitation was good and intestinal diseases, apart from a very small epidemic of mild gastro-enteritis in September and October, were absent.

I wish to thank Col. H. C. Godding, Officer Commanding the Military Hospital, Catterick Camp, for permission to publish; Brigadier G. H. Gilmore, District Army Welfare Officer, Catterick

Camp, for the census of quarters in that camp; Major J. B. Harrower, S.M.O., Catterick Camp, and the medical officers under his command for early reference of cases and information about minor feverish illnesses; Major R. Wigglesworth, Lieut.-Col. R. Kempthorne, Capt. J. R. Edge, and Lieut. P. Venables for help in the care of patients and careful notes; Captain Bernstock for examining the pathological specimens; and Staff Sgt. L. Pitchfork and Privates J. E. Forrester and G. McGarry for numerous routine inquiries and help in preparing the tables.

ABERRANT ENDOMETRIAL TISSUE AND INTUSSUSCEPTION

BY

E. M. SOUTHERN, M.R.C.S., D.R.C.O.G.

Late Resident Obstetrical Officer, St. Mary Islington Hospital

Intussusception of the ileo-colic variety in an adult, with aberrant endometrial tissue at the apex of the entering ileum, is an unusual occurrence. V. B. Green-Armytage (1933) reports that a state of pelvic endometriosis existed in 8.9% of a series of 1,000 abdominal operation cases. Most instances in which aberrant endometrial tissue has been found to involve the peritoneal surface of the intestine are reported in locations about the sigmoid colon and recto-vaginal septum. Thierstein and Allen (1946) report 53 cases of intestinal endometriosis. Their series is subdivided into two groups: (1) 41 cases in which the endometriosis involved the rectum and recto-vaginal septum, and (2) 12 cases in which the lesions were found higher in the intestinal tract. The second group consisted of 6 cases of involvement of the sigmoid colon, 3 of caecal involvement, 1 of endometriosis of the ileum, and 2 of lesions involving the appendix.

Relatively few cases of acute or chronic intestinal obstruction due to endometriosis have been recorded. Glenn and Thornton (1940) report two cases of partial intestinal obstruction of the chronic type due to endometrial tissue. A review of the literature revealed only four cases in which the tissue involved small bowel and produced complete intestinal obstruction. I cannot find a single reported case of intussusception with endometrial tissue as a causal factor.

The justification for recording this case lies, however, not only in its extreme rarity but in the pathological histology, in which there is some evidence in support of the serosal theory of endothelial metaplasia as a factor in the origin of aberrant endometrial tissue.

Case Report

A single woman aged 23 was admitted on July 9, 1947. A year previously, while serving in the W.A.A.F., she had complained of attacks of diarrhoea and vomiting, and a diagnosis of acute food-poisoning had been made. Menstruation had started at the age of 14. The flow was moderate, lasting from

five to six days; the cycle was between 27 and 30 days. There had been severe dysmenorrhoea since the menarche, often sufficient to confine the patient to her bed, and the pain had always been associated with vomiting on the first day of the period. There was no history of pregnancy or abortion.

Three months before admission she had complained of several attacks of sharp colicky pain in the lower abdomen, more pronounced in the right iliac fossa. These attacks recurred at irregular intervals of about three weeks and lasted on each occasion for about half an hour. They had recently become more frequent and prolonged, and seemed to be clearly associated with the menstrual periods. The pain had not been relieved by sedation or antispasmodic drugs. The patient vomited during the attacks, but no nausea or vomiting occurred in the periods of intermission. The appetite was consistently poor. On two occasions there had been some diarrhoea (four or five semi-solid stools a day), but at no time was there any blood-stained discharge in the stools. The first day of the last menstrual period was 11 days before admission.

The patient was thin, lacrimose, and miserable, and was in severe pain, drawing up her legs and constantly retching and vomiting. The pulse was rapid, but regular and of good volume. The temperature was 98.6° F. (37° C.). The abdomen was uniformly tender and there was some guarding of the abdominal musculature. An oval sausage-shaped swelling was seen in the right iliac fossa. The swelling was semi-fluctuant, soft, and mobile. The white blood cells numbered 14,500 (polymorphs 80%, lymphocytes 10%).

The external genitalia were normal. The cervix and uterus were of normal size, shape, and position. A cystic swelling was palpable from the right fornix. This was distinctly felt as separate from the uterus. The mass was tender. Rectal examination confirmed the presence of a pelvic mass. Amongst the possibilities that had to be considered at this stage were appendicular abscess, Crohn's disease, pyosalpinx, extrauterine gestation, rotation of the pedicle of an ovarian tumour, and obstruction from bands or internal hernia.

Operation (July 9).—Under anaesthesia the mass felt like an appendix abscess. A McBurney incision revealed an intussusception of the ileo-colic variety, extending half-way up the ascending colon, which had to be delivered by a separate right paramedian incision. All attempts at reduction failed. A hemi-colectomy was performed and an end-to-end anastomosis of the ileum to the transverse colon was carried out. Both ovaries appeared normal at operation and there was no evidence of pelvic endometriosis.

The patient made an uneventful recovery and was discharged symptom-free on July 29. On Sept. 17 she was found to be well, and the two periods since operation had passed without pain or vomiting.

Pathological Report

The specimen consisted of the resected portion of the terminal ileum, which was intussuscepted into the ascending colon (Fig. 1). The ensheathing and returning tubes had been laid open. For microscopical sections a piece was cut from the ileum at the apex of the intussusception.

Microscopical Description.—Section of the ileum (Fig. 2) showed congestion of the mucosa and submucosa and some necrosis of the mucosa. In the muscularis there were small areas of typical endometrium, composed of glands lined with tall columnar cells in an abundant stroma that was characteristic of endometrial stroma (Fig. 3), but the unusual and interesting feature in this section was that on and underneath the serosa, at the terminal tip of the intussusception and exactly opposite the intramuscular area of endometrium, there was an area showing a most unusual degree of hyperplasia of the peritoneal endothelial cells (Fig. 4). Here the cells were cuboidal, and were arranged to form branching tubules of varying size, giving the appearance of an adenoma. Proliferations of peritoneal endothelial cells, with resulting tubular and cystic peritoneal inclusions, are common in chronic pelvic inflammation, but are very rarely found to the degree shown in this section. The appearance therefore suggested the possibility that this area of peritoneal hyperplasia was an early stage in the metaplasia of peritoneal cells into "endometrial" glandular element. Further, at a point between the endothelial tubules, areas of

JUNE 19, 1948

ABERRANT ENDOMETRIAL TISSUE AND INTUSSUSCEPTION

BRITISH
MEDICAL JOURNAL 1177

typical endometrial stroma might be seen. The picture produced was thus one of invagination of the serosa with accompanying stromal changes.

Discussion

The presence of aberrant endometrial tissue in certain conditions of the ovary was recognized by Russell in 1899

tubes, and finally settled at the site of the future lesion. Sampson has produced a great deal of evidence in support of this theory, and yet many objections to the general application of his views have been raised.

Emil Novak (1926) mentions the following: (1) Though retrograde menstruation may occur, it is a rarely observed phenomenon compared with the great frequency of endometriosis. (2) It is difficult to believe that endometrial tissue thrown off in the uterus could enter the small intestine or the tube travel outwards, and still be capable of implanting itself and growing upon the pelvic structures. (3) Endo-

1.—Resected specimen of ileum with endometrial tissue.

FIG 2.—Aberrant endometrial glands with abundant endometrial stroma within the muscularis of the ileum.

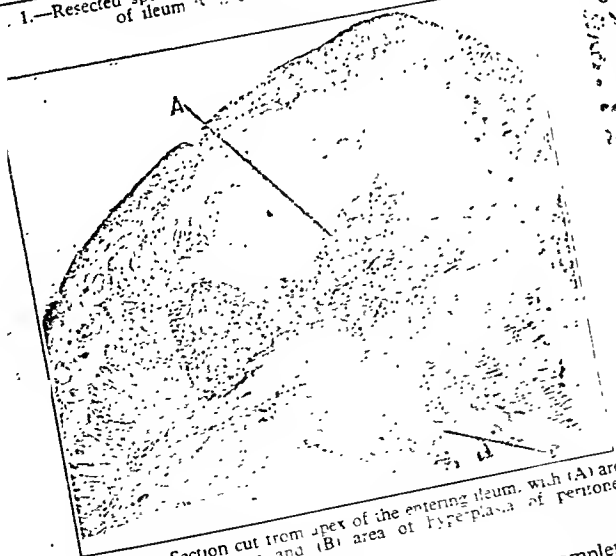

FIG 2.—Section cut from apex of the entering ileum, with (A) area of endometrial tissue and (B) area of hyperplasia of peritoneal endothelial cells. (X5)

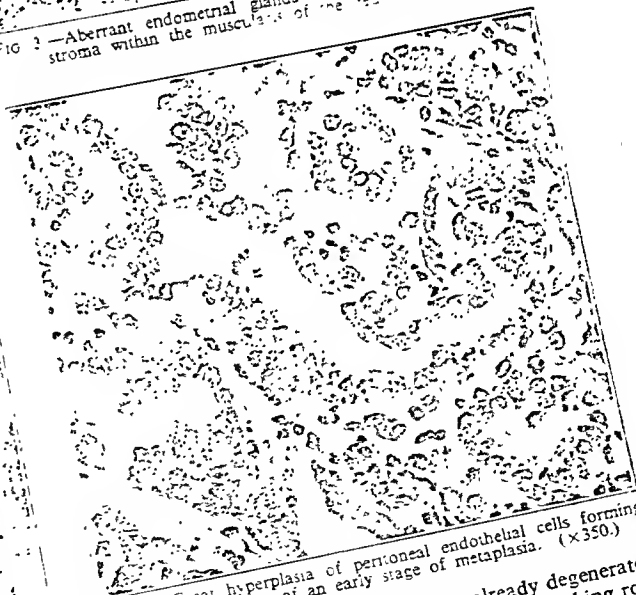

FIG 4.—Great hyperplasia of peritoneal endothelial cells forming tubules, suggestive of an early stage of metaplasia. (X350)

and yet the histogenesis of endometriosis is not completely explained. J. A. Sampson (1921) maintained that these lesions were due to implantations of the living endometrial cells over the surface of the peritoneum of the ovary, etc. These cells were supposed to be cast into the cavity of the uterus during menstruation, passed along the Fallopian

metrium thrown off at menstruation is already degenerated or dead, so that it is not easy to conceive of it taking root in the peritoneum. (4) Experiments such as those of Jacobsen (1922), showing that endometrium can grow in the peritoneum, have dealt with the normal healthy endometrium of animals. (5) Experiments such as those of Heim (1929), in monkeys, in which a utero-abdominal fistula was created, have failed to show any development of endometrium, in spite of the fact that the menstrual blood was emptied freely into the abdomen.

It was suggested by Iwanoff (1898), and supported by Meyer and Kitai (1924), that the origin of the aberrant endometrial tissue was a serosal metaplasia. This was based on the fact that the entire epithelial apparatus of the female genital tract (endometrium, germinal epithelium of the surface of the ovary, etc.) is derived from the primitive coelomic epithelium of the urogenital fold and is a mere modification of the peritoneum. According to this theory, under the influence of ovarian hormonal stimulation the pelvic peritoneum forms tubular invaginations which sink into the subjacent tissue, and the flat endometrium of the involved peritoneum becomes columnar, thus producing an adenomatous condition.

The hypothesis of serosal metaplasia has received influential support, especially for the endometrial cysts of the ovary and endometriosis of the umbilicus, laparotomy scars, uterine ligaments, intestine, and recto-vaginal septum.

An explanation of the stimulus of metaplasia may be found, in the above case, in a study of the behaviour of epithelium in the presence of inflammation. Inflammation beneath a mucous or serous surface produces an infiltrative proliferation in the adjacent epithelium. This epithelial proliferation is at first a protective process, but it can overstep the limit of physiological hyperplasia by producing epithelial tubules which have all the appearances of glandular invasion. Peritoneal endothelium behaves in the same way, and in the present case, in which a chronic intussusception probably gave rise to such a stimulus, the glandular elements are seen to reproduce the exact structure of normal endometrial glands and stimulate a surrounding stroma which is an exact replica of endometrial stroma. Furthermore, these areas of typical endometrial tissue are seen in the sections to lie in immediate apposition to the hyperplastic tubules which are shown to be derived from the peritoneal endothelium.

It would seem that reversions of the epithelium under inflammatory, and perhaps ovarian, stimuli are possible in the adult peritoneum, and that the embryonic cells can reproduce endometrial structure.

Summary

A case of intussusception, with tissue showing all the appearances of endometrium situated at the apex of the entering ileum, is presented.

The microscopical appearances are suggestive of a metaplastic origin of the endometrial tissue and may be held to support the observations of Meyer and Kitai (1924), Novak (1926, 1947), Moench (1929), and others.

I am indebted to Mr. G. C. Dorling, surgical specialist, Archway Group of Hospitals, for help with the clinical notes and for permission to publish the case, and to Miss K. M. Harding, consultant obstetrician and gynaecologist, Archway Group of Hospitals, under whose care the case was admitted. I should like to thank Mr. Moore, of the Central Histological Laboratory, Archway Hospital, and Mr. King, of the Bernhard Baron Pathological Institute, London Hospital, for the photomicrographs.

NEONATAL BACT. COLI MENINGITIS AFTER PROLONGED LABOUR

BY

H. R. DUVAL, M.D., C.M., F.R.C.S., M.R.C.O.G.

Consultant Obstetric and Gynaecological Surgeon,
Coventry and Warwickshire Hospital

AND

J. T. BURROWES, M.A., B.M., B.Ch., M.R.C.O.G.

Registrar, Department of Obstetrics and Gynaecology,
Coventry and Warwickshire Hospital

It is well known that *Bacterium coli* meningitis is relatively commoner in the newborn than in childhood or later life (Barron, 1918; Cruickshank, 1930; Craig, 1936; Rauch and Krinsky, 1940; Barrett *et al.*, 1942). The explanation given is that the newborn infant has not developed adequate resistance against the organism, although in later life it carries the same organism about in large numbers in relative safety (Cooke and Bell, 1922).

The route taken by the infecting organism has been the subject of some speculation, and numerous suggestions have been made. It is generally agreed, however, that the meninges are more commonly infected via the blood stream than by direct spread from adjacent areas. To support this contention Fothergill and Sweet (1933) demonstrated a *Bact. coli* bacteraemia at the same time that *Bact. coli* were found in the cerebrospinal fluid.

The original portal of entry is difficult to determine, but the large number of suggestions made, incriminating widely separated sources, indicate that infection may enter at any of many sites. The following portals of entry have been mentioned: middle ear (Scherer, 1894; Barron, 1918; Leathart, 1932; Craig, 1936), gut (Cooke and Bell, 1922; Barrett *et al.*, 1942; Ravid, 1935), lungs (Aschoff, 1897; Goldreich, 1902; Herrman, 1915), genito-urinary tract (Neal, 1926; Koplik, 1916), spina bifida (Forbes, quoted by Rauch and Krinsky, 1940), umbilicus (Hinsdale, 1899), and morbid conditions of skin, scalp, mucosae, and subcutaneous tissues (Craig, 1936). In addition transplacental bacteraemia, possibly arising from maternal pyelitis, has been suggested by Jakkola (1935), Karplus (1927), and Athenstaedt (1933). Aspiration of liquor infected with *Bact. coli*, causing a bronchopneumonia followed by blood stream spread to the meninges, was suggested by Goldreich in his case. Aschoff held similar views. And, it might be noted, F. J. Browne (1921) considers aspiration of infected liquor a cause of bronchopneumonia.

In the following case it would seem that this was also the method and route of infection. The foetal head lay in the maternal pelvis, deeply engaged, for at least four days, and during the latter two days the cervix was between half and full dilatation. Further, both mother and child showed clinical signs of infection three days after delivery—the mother with *Bact. coli* pyelitis and endometritis and the child with fatal *Bact. coli* meningitis and bronchopneumonia.

Some previous cases have been reported in which the same organism was found in the maternal urine and lochia as was found in the child's cerebrospinal fluid (Jakkola 1935; Trillat and Notter, 1939; Davis and Fernando, 1934).

Case History

A primipara aged 25 had labour surgically induced by Drew Smythe catheter when 38 weeks pregnant. The indication was pre-eclamptic toxæmia with a rising blood pressure

Labour started next day, but it was soon clear that primary uterine inertia existed. Four days later she had two eclamptic fits. She was then given 1 4 gr. (16 mg.) of morphine and sent into hospital.

On admission at 6 a.m. on Aug. 28, 1947, treatment based on Stroganoff's principles was immediately started. In the first 24 hours she received 1½ gr. (81 mg.) of morphine and 6 gr. (0.4 g.) of sodium phenobarbitone. She had a fit when being put to bed and another two hours later but the rest of the day she passed in a semicomatose condition. The foetus was small, with its head deeply engaged in the maternal pelvis. There were no uterine contractions at this stage and the foetal heart was easily audible.

The patient slept deeply throughout Aug. 29. Only 1 6 gr. (11 mg.) of morphine was given. A specimen of urine showed specific gravity, 1010; alkaline reaction; albumin 0.6; sugar nil; scanty pus cells; a few granular and hyaline casts. Sterile culture. At 2.30 a.m. on Aug. 30 the cervix was fully dilated and at 4 a.m. the child, a female, was delivered by forceps. It was somewhat narcotized, but breathed and cried satisfactorily after receiving 1.7 ml. of nikitinamide and 10 mg. of vitamin K intramuscularly. Both mother and child were as well as could be expected for the remainder of the day and throughout the following day.

On Sept. 1 the mother's temperature rose to 100.4 F. (38 C.) and clinical examination suggested acute pyelitis and endometritis. A catheter specimen of urine showed specific gravity, 1024; strongly acid reaction; albumin 0.8; sugar nil; pus cells, numerous organisms, granular and fatty casts; crystals, nil; culture, coliform bacilli. A high vaginal swab showed: direct smear—many pus cells, many coliform bacilli; culture, coliform bacilli. Penicillin was started on Sept. 1, was instituted, and after 24 hours the temperature of the remainder of the puerperium was normal.

The Child

At birth the child was given nose-blowing and an enema and was not disturbed except on the morning of the first day. During the first 48 hours of life (on the morning of the third day the child was found to have refused its feed of water. Some stiffness of the neck and limb rigidity were noticed. The temperature rose to 100.6 F. (38.1 C.). Cerebral haemorrhage was suspected and 100 mg. of 10% potassium chloral were given.

The child's condition deteriorated and 1 cc. of 1% solution of atropine was given. The face and limbs became more flaccid and the chest movements became more frequent. The child was given 100 mg. of sodium phenobarbitone and retraction became more marked. The child was given 100 mg. of sodium phenobarbitone and retraction became more marked. The child was given 100 mg. of sodium phenobarbitone and retraction became more marked.

Before death occurred the child was given 100 mg. of sodium phenobarbitone at the bases of the lungs and 100 mg. of penicillin, 100,000 units, was given. But the child became progressively dyspnoeic and cyanosed, and died at 10.20 p.m. on Sept. 1.

Post-mortem Report. External post-mortem lividity is very marked. Head normal and dura mater is normal. There is no evidence of intracranial haemorrhage or venous sinuses, but there is a well-marked acute purulent meningitis over the base of the brain. The meninges are thickened and contain a large excess of clear yellow fluid. The cerebellum shows marked toxic changes; placental sacs and drainage of both lungs and these show bronchopneumonic consolidation. Abdomen—The peritoneal sac is normal, liver, spleen and kidneys show toxic changes; other organs show nothing of note. Cause of death: Acute purulent meningitis, bronchopneumonia. Culture of pus from the base of the brain—typical reaction of coliform bacilli of intestinal origin.

Discussion

When the membranes are ruptured the way is open for the liquor amnii and the uterine cavity to become infected. This we know to be rare in normal labour or where the induction-delivery interval is short. But when there is

delay in the onset of labour or a prolongation from any cause infection of the liquor becomes an important consideration. And the longer labour continues, with or without vaginal examinations, the greater the degree of infection.

Eventually the liquor becomes frankly purulent and may lead to pyrexia and other signs of toxic absorption in the mother. The risks of caesarean section are greatly enhanced by the possibility of peritoneal and wound infection. At the same time the foetus is surrounded by a septic fluid which enters the mouth, the nose, the nasopharynx, and remains there to be inhaled into the lungs at the child's first breath, or to track down the Eustachian tubes to the middle ear.

Davis and Potter (1946) injected thororast into the amniotic fluid before hysterotomy or caesarean section and found it widely distributed throughout the lung fields of the foetuses. Even if this does not prove that intrauterine respiration occurs, it does indicate that amniotic fluid enters the lungs of the foetus, and if the fluid is infected serious disease of the foetus may be set up, e.g. bronchopneumonia.

Bact. coli is one of the commonest of the bacteria which are present in such a situation, and it is not surprising that this organism is responsible for the majority of meningeal infections in the newborn.

Instrumental delivery, with more or less manual manipulation and trauma, is relatively often required to terminate a prolonged labour, and this will nearly always produce minor abrasions and bruises on the child's scalp, which will be immediately subject to infection. Further, the child in such cases is likely to be born with some degree of cerebral oedema and congestion associated with asphyxia, which in turn favours lung infections.

The possibility of serious neonatal infection must therefore be considered in the management of prolonged labour. And where there is evidence of intrauterine infection, either in the shape of a maternal pyrexia without other cause or in the discharge of purulent liquor from the vagina, chemotherapy should be started, and the case assessed with a view to the earliest possible termination of labour. Woltz and Zittel (1945) have demonstrated that penicillin reaches the foetal blood and the liquor in adequate therapeutic quantities, and recommend its use prophylactically in cases of uterine inertia or unduly protracted labour.

Diagnosis and Treatment.—The diagnosis and treatment of *Bact. coli* meningitis is the province of the paediatrician, but it might be stressed that after a prolonged labour the attendant should be on the watch for early signs of infection in the child and chemotherapy should be started. Sulphapyridine, sulphadiazine, and sulphathiazole alone or in combination with penicillin have been recommended, and Alexander (1946) has had success with streptomycin in one case. Diagnosis is difficult, and it is usually necessary to examine the cerebrospinal fluid in order to differentiate between cerebral haemorrhage and meningitis.

Summary

A short review of the literature is made with particular reference to the portals of entry of *Bact. coli* infection which leads to *Bact. coli* meningitis in the newborn.

The history of a fatal case of *Bact. coli* meningitis in an infant 3 days old is given. The mother had intra-partum eclampsia and prolonged labour, and on the third day of the puerperium developed *Bact. coli* pyelitis and endometritis. The dangers of prolonged labour, from the point of view of the child, are stressed.

We wish to express our thanks to Dr. A. F. Wright, Director of the Coventry Joint Laboratory, for assistance and advice, for reporting on the specimens provided, and for carrying out the post-mortem examination.

CERVICAL SYMPATHETIC PARALYSIS

BY

J. DONALDSON CRAIG, M.D., M.R.C.P.

Research Fellow, Medical Unit, St. Mary's Hospital;
Late Squadron-Leader, Medical Specialist, R.A.F.V.R.

AND

R. C. FULLER, M.B., F.R.C.S.

Extra Surgical Registrar, St. Mary's Hospital;
Late Squadron-Leader, R.A.F.V.R.

The effects of unilateral paralysis of the cervical sympathetic chain, almost invariably referred to in standard textbooks as Horner's syndrome, are generally given as ptosis, enophthalmos, pupillary constriction, and anidrosis of the face on the affected side. This description of the syndrome not only is inaccurate and incomplete but differs from that published in 1869 by Horner himself. Further, accounts of sympathetic paralysis were published by many earlier workers, and it therefore seems justifiable to review the whole status of the eponym.

Historical

Pourfour du Petit (1727) recognized that injury to the sympathetic chain in the neck could cause pupillary changes. In many domestic animals he noted myosis and partial closure of the third eyelid at the inner canthus. His results were confirmed by Mollinelli in 1755 and by many others. Similar effects after section of the trigeminal nerve near the Gasserian ganglion were observed by Fodera (1823), Magendie (1824), and Sir Charles Bell.

Budge and Waller in 1841 demonstrated that the sympathetic supply to the iris has its origin in the anterior and middle columns of the spinal cord from the sixth cervical to the fourth thoracic segment, passing via the spinal nerves to the cervical sympathetic chain and thence to the first division of the trigeminal nerve. Brown-Séquard and Bernard in 1854 noted that section of the sympathetic chain caused pupillary contraction, closure of the eyelids, and increased vascularity and temperature on the affected side, all these changes being reversed by galvanic stimulation of the upper divided end of the nerve.

Despite all these observations, clinical descriptions of such conditions occurring in the course of natural diseases

do not appear in the earlier literature. In 1809 Sir Astley Cooper, in a case of aneurysm of the internal carotid artery, noted ptosis on the affected side together with "a feeling of hot and cold in the ear." He did not record whether or not these signs disappeared after he had eured the aneurysm by ligation of the common carotid artery, nor did he remark on the state of the pupils, an omission which is understandable when it is realized that the pupillary constriction of opium-poisoning was not recognized until Kinnis described it in 1818. Coates, in 1822, recorded a case in which successful ligation of the common carotid artery for an aneurysm was followed by restoration to normal of a pupil which had been markedly constricted. Sir Benjamin Brodie (1828) noted bilateral pupillary constriction in a man with fracture-dislocation of the cervico-dorsal spine. Willebrandt (1854) recorded similar pupillary constriction in a case of cervical tumour, and Gairdner (1855) described an instance of aortic aneurysm accompanied by eye changes which he rightly regarded as similar to those produced experimentally by section of the cervical sympathetic chain.

Notwithstanding the value of these earlier contributions it is probable that much of the credit for the clinical evaluation of the syndrome produced by cervical sympathetic paralysis should be accorded to J. W. Ogle, physician to St. George's Hospital, London. In his carefully reasoned publication (Ogle, 1858) he pointed out some of the fallacies in the application to man of the results of animal experiments, summarized the previous literature, and collected and reviewed a series of 27 cases. In these, unilateral myosis and ptosis were sometimes associated with vascular and temperature changes, and the interference with the cervical sympathetic chain was the result of intrathoracic aneurysms, cervical lymphadenopathy, or spinal injury. He recorded one case in which an acute abscess of the neck was accompanied by dilatation of the pupil, which returned to normal after incision of the abscess. The role of the cervical sympathetic seems to have been well recognized by this time. Weir Mitchell *et al.* (1864) described a patient in whom a gunshot wound of the neck was followed by unilateral pupillary constriction, narrowing of the palpebral fissure, and very pronounced vasodilatation of the corresponding side of the face and neck, ending abruptly at the midline. These changes were confidently ascribed to injury of the cervical sympathetic chain.

The Work of Horner

Horner (1869) based his observations on one case, that of a woman aged 40, who, six weeks after parturition, developed right-sided myosis, ptosis, and diminished ocular tension without evidence of eye disease or of trigeminal paralysis. Although remarking that some slight enophthalmos was present, Horner regarded this as of little importance, concentrating more on the study of the vascular effects. He noted that the affected side of the face was redder and distinctly warmer than the other and that it did not perspire. He measured the temperature on both sides of the face, finding a difference of 5° C. under normal conditions. Bandaging the face resulted in an increase in temperature on the normal side so that the difference was reduced to about 1° C. The vasodilatation of the face when warmer was, he noted, accompanied by a corresponding dilatation of the retinal veins. Atropine enlarged the pupil but slowly, irregularly, and to a lesser extent than on the normal side. Although recognizing that cervical sympathetic paralysis was the cause of the signs he expressed no views as to the fundamental pathology of the condition.

Horner's work appears to have stimulated his associate Nicati (1873), whose observations are remarkable for their anticipation of much of the modern view of the control of the blood vessels of the skin. He distinguished three stages in the development of the paralysis. In the first he considered that the encroachment of the lesion might produce stimulation of sympathetic activity as shown by hyperidrosis of the affected side of the face. Such changes might be found, for example, in cases of cervical abscess, the face returning to normal after this was incised. The second stage, that of early paralysis, he found to be characterized by unilateral myosis, ptosis, enophthalmos, anidrosis, and lowered ocular tension, with flushing and increased warmth of the affected side of the face and neck. Measuring the temperature of the skin of the two sides of the face Nicati found the affected side constantly warmer. In particular, the temperature on the paralysed side did not fall appreciably on exposure to excessive cold and on return to warmer conditions it rose more quickly than on the normal side. In the third and final stage some atrophy and wasting followed. The affected side, formerly highly coloured, was now paler. It was also cooler except when the vessels of the normal side were strongly contracted in response to excessive cold when once again the diseased side became the warmer.

Of Nicati's 25 cases, 20 occurred in women. Although he enumerated the causes of the syndrome fairly completely he was unable to determine any underlying pathological condition in the majority of his own patients, some of whom continued in good health for many years. He fell into the trap of attempting to correlate the syndrome with the ocular changes occurring in exophthalmic goitre, suggesting that excessive sympathetic stimulation might be the *fons et origo* of both the exophthalmos and the thyrotoxicosis, but his arguments are speculative and unconvincing.

From that time onwards the term "Horner's syndrome" appears to have come into common usage to describe the effects of cervical sympathetic paralysis, although the origin of the term is not widely known and the original description little consulted.

Anatomy

The sympathetic nerves of the face and neck are derived from the spinal segments D1 and D2. The fibres supplying the pupil have their connector cells in lateral horn cells of these segments, pass to the anterior or primary rami of the first two thoracic spinal nerves, and thence into the sympathetic chain to reach the superior cervical ganglion. The efferent fibres pass along the coat of the internal carotid artery to the cavernous plexus, whence they may pass to the pupil by one of two routes, either entering the Gasserian ganglion and passing into the first division of the trigeminal nerve, thence into the long ciliary nerves and thus to the pupil, or entering the ciliary ganglion by its sympathetic root, passing through it without synapsing and reaching its pupil by the short ciliary nerves.

The centre for the sympathetic control of the pupil is in the superior corpus quadrigeminum, and the path from here to the spinal cord is believed to be in the tecto-spinal tract. This centre receives fibres from the optic nerve.

The vasomotor fibres of the skin of the face are distributed from the superior cervical ganglion along the branches of the external carotid artery. The vasomotor centre is in the calamus scriptorius in the floor of the fourth ventricle, from which fibres pass to the connector cells of the sympathetic in the lateral horn of grey matter.

The levator palpebrae superioris muscle is supplied by the third cranial nerve through its upper branch. This,

however, supplies only striped muscle, and the ptosis which occurs in cervical sympathetic paralysis is due to interruption of the sympathetic nerve supply to the smooth muscle of the upper and lower eyelids called, respectively, the upper and lower tarsal muscles (of Müller).

A certain amount of misunderstanding has centred upon the subject of Müller's muscle. This term has been applied to the tarsal (or palpebral) muscle described above, and to the orbital muscle of Müller. The latter is a collection of plain muscle arising from the periorbital, bridging the inferior orbital fissure and radiating in a thin layer over the orbital floor. It is variable in size, and is the vestigial remnant of the muscular membrane completing the lateral wall of the orbit in those lower animals in which this does not consist of bone. In certain of these animals it acts as a protruder of the eye (Müller, 1858). In man, stimulation of the sympathetic does not produce protrusion of the eye (Turner, 1862), although this muscle is supplied by the sympathetic. It is difficult to see how this structure can have any notable effect on the position of the eyeball in man.

Pathology

Consideration of these anatomical facts makes it clear that the syndrome may be produced in several ways—namely, (1) by brain-stem lesions, notably thrombosis of the posterior-inferior cerebellar artery; (2) by intramedullary cord lesions at or above the level of D1—if at D1 there will also be wasting of the small muscles of the hand; (3) by extramedullary spinal lesions such as trauma and neoplasm; (4) by lesions involving the peripheral course of sympathetic fibres, such as trauma, aneurysm of the aorta or carotid vessels, or neoplasm in the neck or superior mediastinum; and (5) it also occurs in the rare condition of partial facial hemiatrophy (Parry-Romberg syndrome), the causation of which is as yet imperfectly understood.

The Clinical Syndrome

Whatever the site of the lesion the obvious clinical syndrome is fairly constant. The stage of stimulation described by Nicati is rarely, if ever, seen in present clinical practice, but should be borne in mind as a possible source of confusion in diagnosis.

1. *Myosis*.—This constantly occurs. Although the pupil is small the light reflexes are still present. The pupil does not dilate under cocaine, and the reaction to atropine is slow, irregular, and incomplete. This myosis is greater in lesions involving the superior cervical ganglion than in those arising more centrally.

2. *Narrowing of the Palpebral Fissure due to Descent of the Upper Lid and Raising of the Lower Lid*.—Horner, in his original description, remarked that the degree of enophthalmos was trivial, but in almost every current description enophthalmos is described as a cardinal feature. This is unjustifiable. The apparent enophthalmos is an optical illusion arising from the narrowing of the palpebral fissure. Actual measurements by Pochin (1939) have shown that sympathetic paralysis produces no immediate enophthalmos, such as might be produced by muscular paralysis. Only in long-standing cases is there a very slight degree of recession, of the order of 1 mm. Pochin has also shown the essential difference of the lid retraction produced by sympathetic stimulation and that occurring in Graves's disease. The lower eyelid is lowered in sympathetic stimulation but raised relative to the cornea when the upper lid is retracted by levator palpebrae spasm or Graves's disease. The true exophthalmos occurring in Graves's disease tends to give a false impression of the position of the lower lid. Pochin accordingly rejects the theories of earlier workers that the lid retraction in Graves's disease results from sympathetic overactivity.

3. *Other Eye Changes*.—Hypotonia, depigmentation of the iris, and cataract may occur.

4. *Anidrosis*.—Although the sweat glands are cholinergic they are innervated by the sympathetic, and therefore interference with function will be more or less complete according to the extent of the lesion. This affection is confined to one side of the face, stopping at the midline.

5. *Vascular Changes*.—These are variable, depending to some extent upon the degree of completeness of the paralysis, the rapidity of onset, and the presence of other vascular lesions, especially aneurysm or arteriosclerosis, the latter of which may prevent full dilatation. It is seldom that circulatory changes are as prominent a feature of the syndrome as are the eye changes. Where the lesion is of rapid onset, as in Weir Mitchell's case, loss of sympathetic tone may be followed by vasodilatation persisting even on exposure to cold. The vasodilator fibres, too, are involved, and on exposure to excessive warmth the normal side will show fuller dilatation than the other. But with the passage of time compensatory mechanisms are brought into play, the arteries and arterioles regaining some of their lost tone, so that actual pallor may develop, or the vessels may remain in a permanent state of incomplete relaxation. It is not true to say that the paralysed side is always warmer than the normal, although this is so under the usual environmental conditions of temperate climates. The temperature tends to remain relatively constant, failing to show the normal wide variations that follow those alterations in vasomotor tone which ordinarily result from fluctuations in surrounding temperature.

6. Some degree of facial hemiatrophy may occur in established cases, although this is never so pronounced as in the Parry-Romberg syndrome.

Summary

The inadequacy of many current accounts of the effects of cervical sympathetic paralysis is noted.

The history of the condition is reviewed, with particular reference to Horner's original account.

The anatomy, pathology, and clinical features of the syndrome are discussed.

As a result of this survey it is concluded that retention of the eponym "Horner's syndrome" is fully justified.

DAY NURSERIES AND THE MAN-POWER PROBLEM

BY

W. E. CAVENAGH, B.Sc., D.P.A.

The writer of a leading article on day nurseries and industry (*British Medical Journal*, 1947, 1, 644), after considering the results of recent research into the well-being of the children concerned, stated that the cost to the latter was such as cannot be justified except on grounds of overriding national economic need. He went on to say that if, as seemed to him probable, day nurseries consume as much or more labour than they free all basis for urging women to take up full-time work and leave their young children in a nursery disappears. This conclusion was partly based upon the Luton investigation made by F. Grundy in 1943.

There are really two questions to be considered: Do the day nurseries economize the use of woman-power?; and Does the economy, or the redistribution of labour involved, result in an increased supply of labour to work of national importance? The results of an investigation made in Birmingham in 1945 are interesting in this connexion.

During the whole of the war the labour shortage in Birmingham was such that a continual stream of men and women were moved from their homes in other parts of the country to work in Birmingham. At least 80,000 are actually recorded as having been brought in, placed, and billeted directly through the transfer and accommodation machinery set up by the Ministries of Labour and Health. Innumerable others drifted in on their own. This was the scale of the man-power problem which led to the setting up of 72 day nurseries and five 24-hour nurseries—the largest number of wartime nurseries set up by any local authority outside the L.C.C. The scheme was definitely intended as one of the alternative solutions to the problem of labour supply in the area.

The nurseries were almost continuously short of staff and from 1942 the number opened lagged well behind the direct evidence of need shown by the long waiting-list but gradually the Child Care Reserve and other schemes for the training or retraining of staff, together with the working of the National Service Orders, did much to clarify and stabilize the position.

The Ministry of Health in a circular letter to local authorities in August, 1940, had suggested that one staff to every five children attending would be necessary, but this was found insufficient in Birmingham, where the nurseries were open from 7 a.m. to 8 p.m., to cover the long hours worked by many mothers, and the wide variety of starting and stopping times. A number of attempts were made to shorten nursery hours, but owing to the large number of small factories concerned—a feature of this area—this proved impossible, and as a result overlapping shifts were worked with a total ratio of one staff to every four children (rather more in the 24-hour nurseries).

In June, 1945, the Public Health Department drew up the following picture of the provision made:

Nurseries and the Children

Capacity	3,695	Under 2	1
Vacancies	223	Over 2	2
Children on register ..	3,472	Mothers on register ..	3

Employment of Mothers

Employment	Full-time	Part-time
Factory	1,448	169
Transport	100	6
Canteen and waitresses ..	277	30
Shop assistants	293	34
Domestic	234	64
Other work	432	56

In Birmingham not more than two children from one family were accepted, and the number of mothers (3,143) was very high as compared with the number of children (3,472). On the Birmingham ratio the staff used for this number was 868, and so there would be a release of about 2,275 mothers, or 3.6 for each member of staff.

But this figure does not give a realistic picture of the nurseries from the man-power aspect. Of the mothers 359 were part-time workers and may be considered as equal to only half their number of full-time people. Again, the actual attendance of children was on an average only about 75% capacity, representing proportionately fewer mothers. Moreover, mothers temporarily off work through sickness were still allowed to send their children to the nursery for a period not exceeding three weeks, and although it is not known what allowance should be made for this factor it is clear that not every child attending had a mother at work at the time.

On the staff side Public Health Department records show that there were about 140 other people directly employed—e.g., cleaners and others, mostly part-time but equal to at least 70 full-time people. Behind the staff directly attached to the nurseries there were the other people, such as the doctors who inspected all nurseries once a fortnight, the extra staff at central kitchens, and all those involved in the erection of huts, adaptations of houses, equipment, alterations, and repairs.

Each of the nurseries when fully staffed used three highly qualified people (nurses or nursery nurses), all in the short-supply category, plus nine to eleven others according to the size of the nursery, and in estimating the man-power contribution this must be considered. The nurseries were not allowed to recruit staff between the ages of 18 and 25, but most of their workers could have done other forms of national work, although of course the 14-year-olds could not have been directed, and even who had children of their own (sometimes accommodated in the nursery) would also have been free from compulsion.

Since the issue of Circular 2388 by the Ministry of Health in May, 1941, it has been possible for *...the mother and a woman who is in employment* to use the nurseries not only the children of women on work certified as essential to the war effort. As women with young children were not affected by the National Service Orders, and were outside the Control of Employment Order, they could offer their services to, and be engaged on, employment without reference to the Ministry of Labour, and there was no control over the kind of work they did. The categories which from this angle might be regarded as doubtful are "shop assistants," "domestic," and "other work." These account for 959 mothers on full-time and 152 on part-time, being one-third of the total of mothers. Although doubtless many of the domestics were in hospital work, and the shop assistants in food shops, there is still a factor which, if fully known, might still further affect the picture.

In relating wartime experience to present needs it must be remembered that these nurseries were set up against a background of labour controls and comparatively high earnings on national work. Married women generally are now free to work or not as they please, but these nursery schemes were aimed particularly at the mothers of young children, and the present sliding scale of charges, with the high maximum, while deterring the better-off mother encourages the poor one. There are long waiting-lists, and it is time that the general public asked themselves whether they are satisfied with a situation in which young mothers of the working classes are driven by economic necessity to work outside the home while their young women generally and all women over 41 are free to work ever shorter hours.

During the war there was a rough check on the use of labour which was outside the controls in that, owing to the "vetting" operations of the District Man Power Offices, their engagement might result in the withdrawal of other employees. These powers have now practically disappeared. On the employees' side the cessation of munitions production has lowered earnings and reduced the financial attractions of national work as compared with other jobs. It is therefore less likely now than before that these mothers will be drawn towards work of high priority.

It is arguable that even during the war most of the mothers who placed their children in nurseries would have been working if the nurseries had never existed, as a great deal of paid minding at higher rates was known to have been going on in this area for years. Nurseries may simply have displaced minding in many cases by their extraordinary cheapness (6s. a week), the extra rations, and the long hours. Which form of child care was better for the children's welfare is quite another question, but since most of the minding was done by elderly relatives, not themselves in the labour market, any such displacement must actually have been detrimental to the labour supply situation.

One final point: since the withdrawal of the 100% grant by the Ministry of Health the charge per child has been raised to 18s. to cover the difference between the general grant aid received by the nurseries as part of the Maternity and Child Welfare provision by the authority and the actual cost, which is in the region of 35s. As the mother's payment is scaled according to her means, in some areas not more than half a dozen children in each nursery are being paid for at anything like the full charge, and the working of the scales is becoming a mounting burden on the rates. This expense may be more than justifiable looked at as a child welfare service, though even from that angle it would seem that allowances to necessitous mothers enabling them to look after their own children would probably serve the purpose more effectively. From the point of view of the national man-power problem, however, the arrangement would at best appear to result in a more than doubtful contribution to national labour needs at local expense.

Medical Memoranda

Benign Ulcers of the Greater Curvature

It is a general rule, subject to few exceptions, that the nearer to the pylorus, and especially to the greater curvature, the greater is the probability of malignancy in an ulcer. Thus the Mayo Clinic found malignancy in 10% of lesser-curvature ulcers, 65% of pre-pyloric ulcers, and 100% of greater-curvature ulcers.

There are many experienced surgeons and radiologists who have never seen a benign greater-curvature ulcer, whereas malignant ulcers involving the greater curvature are by no means a rarity. Up to the time of writing only 17 proved cases of benign greater-curvature ulcers had been recorded. The following is a report of the 18th case.

CASE REPORT

The patient, a woman aged 66, gave a history of "bilious attacks" for five years, worse during the last six months, with increasing anorexia, attacks of vomiting, abdominal distension, and constipation. Abdominal pain was not an important symptom, nor was any mass felt on palpation. A blood count showed: red cells, 2,500,000; haemoglobin, 48%; colour index, 0.9.

At a barium-meal examination I found a large ulcer crater on the greater curvature, at the junction of its middle and lower thirds

(see Fig.). The mucosal pattern above and below the ulcer was normal, but at the base of the ulcer convergent widened rugae were present. Tenderness on pressure was localized to this area and also to the region of the duodenal cap, which showed constant deformity. The greater curvature for 2 in. (5 cm.) below the ulcer was crenated.

The radiographic mucosal appearance of the ulcer suggested innocence, but its position was strong evidence in favour of malignancy. It was decided to operate, and I am indebted to Mr. G. Bohn for the following extract from his operation findings. "There was a large apparently innocent ulcer on the greater curvature of the stomach, with much induration around it. There was also a

large duodenal ulcer which was attached to and penetrating into the pancreas. On opening the stomach before fixation I found two ulcers and the scar of a third ulcer all lying exactly on the greater curvature and joined together by thin white scar tissue. The biggest ulcer, which was the most proximal of the three, contained an artery in its base. I carried out an anterior Polya gastrectomy, the section through the duodenum being just proximal to the ulcer there." The patient made an uninterrupted recovery from this operation.

Histological examination by Dr. J. Mills of the large ulcer (1 in. (2.5 cm.) in diameter and situated 4 in. (10 cm.) from the pylorus) showed "a typical benign peptic ulcer, the floor of which is composed of fibrosed fat, lined on the gastric aspect with inflammatory exudate. Near the gastric surface is a large vessel, which no doubt opens on the surface at some plane other than that of the section."

COMMENT

The operative finding of multiple greater-curvature ulcers is unique. That only the largest crater was demonstrated radiographically is understandable in view of the marked crenation of the greater curvature.

Before 1914 no single proved case had been recorded. There are records of 36 cases without histological examination. Between 1914 and 1928 there were 10 proved cases, mostly suggested by Continental authors. A brief analysis of the last 9 cases has been tabulated with the object of disclosing any factors which they may have in common. The series is of course too short to have any statistical value, but the figures suggest that the condition usually occurs in the more advanced age groups. The average age is 52. The distance of the ulcer from the pylorus varies between 1 and 5 cm., with an average of 3 cm. There is no common factor in the symptomatology, and diagnosis must be based on the radiological and histological findings.

This appears to be the first record of multiple benign ulcers on the greater curvature.

Author	Patient		Symptoms	Ulcer		Remarks
	Sex	Age		Diam.	Distance from Pylorus	
Matthews (1935)	F	57	Epigastric pain 2½ hours p.c. Duration 35 years. Relieved by food. No vomiting or hæmatemesis	1 cm.	12 cm.	Subtotal gastrectomy; well after 5½ years
Matthews (1935)	M	57	Epigastric pain 2 hours a.c. Duration 1 year. No vomiting or hæmatemesis	1.5 cm.	14 cm.	Subtotal gastrectomy; well after 15 mths.

Dr. William P. Forrest addressed the International Conference of Social Work at Atlantic City recently on the World Health Organization and social medicine to-day. He said that, though of professor of social medicine had collected 100 different definitions of the term, he himself regarded social medicine as a philosophy rather than a subject. It was part of the belief that medicine should no longer be taught or practised from a negative outlook. He would like to see medical students prohibited from studying anything divorced from its context. Discussing the health visitor, he thought they should give her fewer families to look after and more duty to perform. They would thereby greatly decrease the number of official visitors to each household in favour of one welcome visit. There might be families who enjoyed being visited by a 'stream' of social officials, but he hoped they were in the minority. The health visitor could easily undertake the duties of the school nurse, the tuberculosis nurse, the venereal diseases nurse, the friend of unmarried mothers. She could become a most remarkable and essential agent of all or nearly all the departments concerned with social service.

Reviews

DERMADROMES

DERMADROMES
Skin Manifestations of Internal Disorders (Dermadromes) By Kurt Wiener, M.D. (Pp 690. 386 text illustrations and six colour plates. 63s.) London: Henry Kimpton 1947

This book will be a useful work of reference to both general physicians and dermatologists. Many writers in the past have emphasized the close connexion between internal complaints and external manifestations on the skin but we do not remember anyone's undertaking the formidable task of collecting and classifying them. The magnitude of the work may be gauged from the size of the volume and the number of references, which exceed 3000. The author considers that the works and their authors referred to should not be hidden away out of sight on that page where that work is mentioned instead of being listed at the end of each chapter or relegated to the end of the book, and he has therefore adopted the system of consecutive numbering beneath the main text. He hopes that the reader may be encouraged to look up some of the original sources himself. He has also inserted a "word-dermadrome"—which denotes any phenomenon on the skin that accompanies an internal disease. I must not say too much about this book. Finally, I must say that it is a better word than many of the terms which are used in dermatology.

Although attempting possible the author has constitute entire division skin manifestations of infancy. Many write matters, and although their inclusion would volume. The word sy Among diseases in w and often serious are discusses these and th many of the manifest are seldom seen exce where they effectively an enormous subject to to practise, since the a score of common d with the interest the and we warmly recor clear and well repro

PSYCHO-ANALYSIS IN SELF

Sigmund Freud 4
D.Phil. The Inner-
Reconstruction (Pr
Trench, Trubner and

Dr. Hollitscher has a summary of the basic Freudian psychology for logists, for whom some understanding of it is an account of Freud's formulations are that and adherents. Freud, and again and again extension of his theory other factors, such as kind.

The charge can be made that Freud's spiritual descendants that they have neglected the spiritual structure which has few points of contact with the physical fields. His disciples have

built up and up instead of downwards to the ground. Had they pursued the latter course we might have seen real advances, instead of increasing mysticism and dogmatism and a schism of the churches. To take but one example. Freud's theory of the unconscious was a notable advance for 50 years ago, but in its presentation of anthropomorphized antagonistic "ideas" and the "censor," as if they were things rather than processes it is out of touch with modern medicine. Nevertheless, Freud's "unconscious" is directly translatable into neural concepts. So much cannot be said of some less fundamental concepts to which a central position has been given, such as the castration complex. It is frankly incredible that all modern theories of sex with castration nowadays start from the fact that the infant is in utter ignorance of their sexual functions, that the infant in the process of being born is a state of some kind of upheaval which disturbs the economy of its functions in such a way that subsequent experience of anxiety is related to this birth trauma. However, not all psychoanalysts will embrace these ideas. Before Freud in psychology can do so, it is necessary to have a more general structure of science it will have to be based on the results of the test of critical experiment to which the Freudian has not much inclination.

CORRECT DIAGNOSIS

[illegible]

The book opens with a long chapter on the principles of diagnosis and her application to the integrative approach. Thereafter find it an interesting and instructive review of various theories of the signs and special indications of considerable value. They reiterate the conviction that although it is difficult to state precisely what makes outstanding diagnosticians, a characteristic of such clinicians is that they consider all possible causes of the various symptoms and signs if only to dismiss them. The authors therefore include many lists of diseases which may present with given symptoms or signs. These lists gain in significance through being based on the practical experience of the authors or of other medical authorities. The style is refreshing for the book is enriched with many classical descriptions of disease, enlivened by pointed and amusing anecdotes, and spiced with American colloquialisms. The reviewer believes that physicians will read this book with pleasure and profit.

SIDNEY TRUELOVE.

A CORNISH HOSPITAL
Cornwall Hospital, Penzance

A CORNISH HOSPITAL By Dr.
A History of the West Cornwall Hospital, Penzance. Truro: Oscar Blackford,
E. C. Edwards. (Pp. 47. No price.)

Dr. Edwards is to be congratulated on having recorded the history of the West Cornwall Hospital, especially at this time when the fruits of public charity have been deemed ripe for plucking by the State. We may well be proud of our hospitals and of the men and women on whose enterprise and generosity

they depend. The wave of charity which began in London in the early eighteenth century rolled on in the course of time to the provincial cities and towns, so that before long there were few of any importance which did not boast of an infirmary or a dispensary.

Founded in the year 1809 as the Penzance Public Dispensary and Humane Society, it became sixty years later the West Cornwall Dispensary and Infirmary and later still (in 1929) the West Cornwall Hospital. Credit for the foundation of the hospital goes to Dr. J. B. Borlase and also to two early benefactors, W. H. Hoare, of London, and Sir Richard Acland. When Borlase, "our lamented friend and leader," died in 1813, his place was taken by the "excellent, talented, and zealous" Dr. James Montgomery, whose family service ceased only in 1908 on the death of his grandson, Dr. Hugh Montgomery. The first committee provided facilities for vaccination and also for the resuscitation of the apparently drowned. They equipped themselves with Dr. Fothergill's latest apparatus, to supplement if not to supplant the bleeding that was then the vogue, and went so far as to offer rewards to any who rendered service to shipwrecked mariners. The local tradition for their care has persisted to this day, and to the everlasting credit of this hospital stands their special record of service during the dark days of 1917-18, when the U-boat campaign nearly succeeded in bringing about our downfall.

The committees seem to have been fortunate in their choice of officers and servants, though it is disquieting to read that Jane Eva, who with her mother Anne acted as housekeeper for almost forty years on a modest wage scale of from 2s. to 2s. 6d. per week, was found guilty of "taking in lodgers" and of "allowing disorderly Females to congregate in the passage during the hours of Divine Service on Sunday Evening last." These misdemeanours, which were her undoing, seem to have resulted from her inordinate liking for the merry company at the Turks Head. There are the usual headaches for hospital committeemen, such as accounting for all the leeches purchased and finding sufficient money at the time it was wanted, but on the whole the people of Penzance seem to have given their institution the support it deserved. The committee, too, seem to have been intelligent and broadminded, for we read that in the year 1824 they sent their dispensing apothecary to London for the purpose of improving his professional abilities.

It is to be hoped that Dr. Edwards's apprehensions about the future of voluntary hospitals under State management will not be justified by the course of events. The voluntary hospital, so fundamentally Christian in its tradition, has a deservedly warm place in the hearts of our people, and any interference in its essential nature could not be tolerated.

W. H. McMENEY:

CATALAN SURGERY

Diagnóstico y Terapéutica Quirúrgicos de Urgencia. By Dr. F. Domenech-Alsina. (Pp. 912; 330 figures. No price given). Barcelona-Buenos Aires: Salvat Editores, S.A. 1947.

In 1936 the author of this book published in collaboration with Manuel Corachán *Diagnóstico y Terapéutica Quirúrgicos de Urgencia*, a book that was an outstanding success, and despite its having been reprinted in Buenos Aires it has been long out of print. Following the unfortunate death of Prof. Corachán in 1942 the co-editor has published the book anew. He has changed the title and reviewed the text, so that it now incorporates all the lessons learned in recent years about emergency surgery.

In spite of its being a book mainly based on personal experience, the majority of the views set out in it may be considered to be those of the Catalan school of surgery, and the author expresses in the preface his gratitude to a number of prominent Barcelona surgeons who have contributed by their advice or with their material to the completeness of the work. The book is divided into two main parts: the first on general problems, shock, surgical infections, burns, etc., and the second on the diagnosis and treatment of the acute surgical emergencies. The presentation is excellent and the bibliography is fairly complete. It is a book which will be useful to students, undergraduates, and postgraduates alike.

LONDON

SATURDAY JUNE 19 1948

AUTONOMY IN ORGANIZATION FOR SPECIALISTS

With the approach of the appointed day consultants and specialists are taking a lively interest in the organized representation of their interests in the National Health Service. The B.M.A.'s proposals for consultants and specialists organization were set out in the annual report of Council, and the part of the report dealing with this was reprinted in the *Supplement* of May 22. The whole matter will be discussed at the Annual Representative Meeting in Cambridge, when there will be the opportunity to debate the method of election, the kind of representation, and the functions of the central and peripheral committees. There will, for example, be the motion by Bournemouth asking that the Central Consultants and Specialists Committee "shall be an autonomous body with full powers to determine policy on consulting and specialist hospital matters and action thereon subject to the final sanction of the Association." It is probable that the decisions of the Committee will be subject to the final approval of Council. But even if the B.M.A. goes as far as, they may at present be inclined to do, in the aspects of the policy of the Association.

There is clearly a need to take account of the wishes and needs of the insured in the first time they come to the insurance service, and new methods of working in this situation. The Association is flexible to allow for the wishes of the insured and specialists will be able to make a motion, wish to have their terms of reference, and a model of the Insurance Company controlled by its general policyholders. Consultants and specialists will be able to have a general conference and a general policy laid down by the general policyholders. The Association will act on its own responsibility and will not be subject to the veto of the Council of the B.M.A. or the Representative Body. If the Association is the wish of the consultants and specialists generally to remove that no obstacle would be put in their way. The B.M.A. is a voluntary organization, and if an important section of its members wish to order their affairs in a certain fashion the elasticity of the voluntary principle will make it possible for them to do so. At the same time the Consultants and Specialists Committee may find it useful in certain matters to secure the backing of the B.M.A. Council and would not, we believe, wish to exclude this possibility.

Criticism has been a traditional method of representation in the regional and national committees. It is claimed

that the teaching hospitals should have a larger and even perhaps dominant voice in matters which concern the terms and conditions of consultants and specialists in the new service. No one is likely to underestimate the importance of the teaching hospitals, but their predominant influence, as is that of the Royal Colleges, is in the academic field. The Spens Report, it should be remembered, advocates equality of status among the hospitals in the National Health Service. Though this is an ideal to be aimed at, it is unlikely that the teaching hospitals will ever lose their supremacy. But the margin of difference between teaching hospitals and non-teaching hospitals is to be hoped, progressively narrow. This being so, it may be questioned whether a minority of hospitals should have a disproportionate representation either on the peripheral or in the central committees. All of these matters are open to reasonable settlement in a way most acceptable to the majority of consultants and specialists.

It would be regrettable if personal antagonisms or institutional rivalries were allowed to fog a fairly simple issue. To divide and so weaken the profession by setting up a new organization with a new and inexperienced secretariat as has been suggested, would be a step that we believe, to commend itself to the whole body of Generalists and Specialists. The Royal Colleges have sometimes been criticized, and often unfairly, for inaction. Their historical development has certainly favoured autocracy and working of the highest administration as they are, they are not instruments fitted for the medico-political work necessary for securing satisfactory terms and conditions of service for consultants and specialists after July 5.

THE PROFIT SLAVE

In the last hundred years the death rate from tuberculosis has been falling steadily. At present it is only about one-tenth of what it was in 1851. The greatest diminution has been in the early years of life. Up to the first decade of the present century the mean annual death rate was highest in infancy and early childhood, but since then a change has occurred. The infantile death rate has continued to fall, whereas that in young adults, especially young adult females, has remained more or less stationary, with the result that the highest death rate now is in females aged 20 to 25 years. What is the reason for this? Numerous explanations have been put forward, but none of them is supported by sufficient evidence to be convincing. The continued high death rate from pulmonary tuberculosis in young women is still an unsolved problem and presents a challenge to all those who are interested in overcoming what is the major infectious disease of Western civilization.

In an attempt to throw some light on this problem the Royal College of Physicians decided to conduct a survey of the incidence of tuberculosis in selected groups of young adults, with the special objects of following the natural history of the infection from its earliest stages and of determining which persons or groups of persons are most likely to develop clinical disease.¹ The project was made

¹ *Tuberculosis in Young Adults: Report on the Prophit Tuberculosis Survey 1935-44*. Royal College of Physicians. 1948. H. K. Lewis, London. 30s.

possible by a bequest of the late Mr. J. M. G. Prophit, and was guided by a widely representative committee under the chairmanship of the President. Observations were made over a ten-year period from 1935 to 1944. Ten thousand presumably healthy young adults came under observation; they belonged to five groups—contacts, nurses, medical students, naval entrants, and controls—and were examined at yearly or sometimes six-monthly intervals by chest radiography and by the graded Mantoux intradermal tuberculin test. The subjects were followed up for varying lengths of time to see what proportion developed tuberculosis. Owing to difficulties caused by the war observations on some of the groups had to be curtailed, and attention became focused mainly on nurses. The work was carried out by three Prophit scholars—Dr. Ridehalgh, Dr. Daniels, and Dr. Springett—to whose high purpose and unflagging zeal under most trying conditions the success of the investigation must be mainly attributed.

The high incidence of tuberculous infection was revealed by the initial tuberculin test; the proportion of subjects reacting to 1.0 mg. or less of old tuberculin ranged from 64% among the naval entrants to 93% among the contacts. Omitting the naval entrants, who were not followed long enough, the rate at which infection occurred was greatest in the nurses and least among the controls. Thus nearly all the nurses who were tuberculin-negative originally, three-quarters of the medical students, and rather over half of the controls become tuberculin-positive within three years of entering the survey. At the time of Mantoux-conversion about 30% of the subjects suffered from transient symptoms presumably related to their infection, and in 8% lesions of the lung were discovered soon afterwards on radiographical examination. Subsequent observation showed that just under half of those with radiographic changes soon after conversion developed tuberculous disease, as opposed to one-twentieth of those in whom no such lesions were detectable. This finding is of considerable importance, since it emphasizes the need for supervising young adults after Mantoux-conversion.

A further aid in estimating the risk of breaking down was provided by the degree of reaction to the tuberculin test; the higher this was shortly after Mantoux-conversion the more likely was tuberculous disease to develop. Moreover, in general terms, the greater the degree of exposure to infection, whether in initially tuberculin-positive or in initially tuberculin-negative subjects becoming positive, the higher was the tuberculosis morbidity rate. As other workers have found, the disease occurred more often in those who were tuberculin-negative originally and became positive while under observation than among those who reacted to tuberculin on entry. A further difference between these two groups was that when infection did progress in those who had recently become Mantoux-positive, clinical symptoms generally appeared within a year of conversion, whereas in the initially Mantoux-positive reactors the incidence of tuberculous disease was low in the first year, but tended to increase with each year of nursing experience. Among nurses genetic immunity clearly played a part; the disease was commoner in girls from Wales and Ireland than in English girls, though there was no evidence that it ran a more fatal course.

The report has something of value to say on the prognosis of the minimal lesion. Of 68 cases diagnosed on entry to the survey and followed up for the sake of interest, 51% proved to be progressive and 49% retrogressive or stationary. Of 97 cases arising after entry to the survey and observed for an average period of two and a half years, 45% became clinically active, 28% showed radiological evidence of local spread or of fresh foci elsewhere without developing symptoms, and 27% were non-progressive. On the whole, these observations confirm those of other workers and show, as pathologists know quite well, that a considerable proportion of pulmonary lesions large enough to be detectable by x-ray examination undergo natural healing without special treatment. What we want to be able to do now is to pick out from among the group of persons showing minimal lesions those that are most likely to prove progressive. It is encouraging to learn that this subject is under study in a fresh survey of the Prophit committee.

There is a mass of data in the report which will interest students of tuberculosis. We have, however, already mentioned sufficient of the main findings to indicate some of the lines of action that are called for. It is evident that, if tuberculosis in the young adult is to be diagnosed at an early stage when treatment is most effective, all persons of 18 years of age or over should not only be kept under general medical surveillance but should be tuberculin-tested periodically and, when necessary, x-rayed. Those reacting negatively to tuberculin are known to be free from infection and therefore need not be x-rayed but should be tuberculin-tested at intervals. Those reacting positively should be x-rayed, and all those with a pulmonary lesion should be kept under close supervision. The chances of their developing clinical tuberculosis are greater if they have a high degree of sensitivity to tuberculin than if they are only weakly sensitive, and more attention should therefore be paid to the strong reactors. Tuberculin-negative reactors who become positive should be x-rayed at once. Those with pulmonary lesions who have at the same time a high degree of tuberculin sensitivity should be taken off work completely or prescribed a light régime of duty. In the experience of the Prophit survey about half of the persons in this category developed tuberculosis; they deserve, therefore, special attention. Over 90%, however, of those undergoing Mantoux-conversion have no signs of pulmonary disease on x-ray examination, and their chances of developing tuberculosis are only one-twentieth of those with radiological lesions. If tuberculosis does develop in these persons it tends to develop soon, and probably all that is required is to keep them under general supervision, and repeat their x-ray examination every three to six months for a year or two. If these measures were taken and if at the same time attention was paid to improving the nutritional state and correcting faults in environment and mode of life it should be possible to effect a material reduction in the amount of tuberculous disease in the young adult population, and probably an even greater reduction in the number of fatal cases.

In the final passages of his introduction to the report the President wisely raises an issue of even greater importance than the problems investigated by the Prophit

scholars. It concerns the whole of our attitude towards tuberculosis. Are we to restrict ourselves, as we have in the past, to the treatment of the individual patient, or are we to direct our efforts against the prevention of the disease itself? There is good reason to believe that if tuberculosis could be regarded like other infectious diseases, and if measures could be taken to prevent infectious persons from transferring their tubercle bacilli to other members of the community, greater progress would be made in a few years towards control of the disease than is ever likely to be achieved by our present methods. The problem is an epidemiological and social one, and under the new National Health Service its solution might well form the main task of medical officers of health, who, freed from routine hospital duties, should be able to concentrate attention on their most important duty—the prevention of unnecessary disease.

MENTAL HEALTH ADMINISTRATION

The National Health Service brings changes in the field of mental health administration as in every other branch of medicine. The Board of Control, now re-established in London after seven years' exile at St. Anne's on Sea, welcomes the integration, central and local, of the mental health services with the National Health Service. The annual report¹ for 1946 describes how centrally the administrative functions of the Board will be transferred to the Minister of Health. Its members and officers will in future act as the Minister's officers, though the Board will retain its quasi-judicial functions in relation to the admission and detention of patients where questions of the liberty of the subject arise. As local health authorities the county councils and county borough councils will be responsible for the initial care of patients under the Lunacy and Mental Treatment Acts, and in certain circumstances for after-care. They will also be responsible for the ascertainment, supervision, guardianship, and community training of mental defectives. It is believed that in the integrated service there will be opportunities for expanding the scope and increasing the efficiency of mental health provision. A closer association between psychiatry and general medicine is expected and a further breaking down of that isolation by which in the past the treatment of mental illness has so often been handicapped.

More than half the admissions to mental hospitals in England and Wales in 1946 were voluntary. This is more than twice the number obtaining in 1938 and is an encouraging indication of a greater public awareness of the importance of early treatment. The 25,326 discharges during 1946 represented 71.2% of the direct admissions, compared with an average for the preceding five years of 67.1%. This discharge rate, the highest ever recorded, is again largely due to the number of voluntary patients who seek early treatment. Many of them are quickly restored to health and leave after a short time. The number of voluntary patients admitted during the year was 18,059, and of 16,183 discharged 6,154 were recovered, and 7,603 relieved, the remainder being put down as "not

improved." Only 351 voluntary patients out of a total of 17,208 such patients in mental hospitals were transferred to certified status; on the other hand, 823 certified cases were regraded as voluntary patients.

Some form of physical treatment is now used in every mental hospital to supplement other methods of approach. The Board has watched the development of prefrontal leucotomy, and considers that for certain types of cases this operation offers "a probability of relief and the possibility of recovery." Occupational therapy for recent cases and for patients in the early stages of illness is now given an important place in most hospitals; the Board wishes that its use for chronic patients was more clearly recognized.

In recent years there has been a steady rise in the number of admissions to mental hospitals, and in spite of the present high discharge rate the mental hospital population of England and Wales is increasing. In 1946 there were 35,585 admissions, 6,009 more than in 1945 and 8,148 more than in 1938. The total mental hospital population at the end of 1946—namely, 134,920—was higher by 1,113 than at the beginning of that year. The proportion of women residents was 57.2% and of men 42.8%.

The death rate expressed as a percentage of the daily average number resident was 7.55, compared with 6.81, which was the average for the pre-war quinquennium 1934-8. Owing to the late receipt of the general mortality statistics, the causes of death cannot be given completely for 1946. In 1945 by far the most frequent cause was disease of the coronary arteries, with pneumonia next in order, followed at a great distance by senility, pulmonary tuberculosis, intracranial lesions of vascular origin, and cancer. The death rate from tuberculosis in 1946 was lower than in any year since 1939, and the number of fresh cases lower than in any year since 1940. Dysentery showed an incidence rate of 9.0 per 1,000, the lowest figure since 1940, and a death rate of 0.1 per 1,000, the lowest for the last decade.

The effect of the Education Act, 1944, is clearly seen in the increased number of children notified by local education authorities as mentally defective. The number of such children in 1946 was 4,209, or nearly 1,000 more than in 1945 or 1944. The number of mentally defective persons in institutions or under statutory care in the community is close on 102,000. In the institutions for mental defectives the proportion of deaths during the year to the average number resident was 13.4 per 1,000. The chief causes of mortality were pneumonia, heart disease, tuberculosis, and epilepsy, in that order.

Shortage of accommodation is still a serious problem. At the beginning of this year there was overcrowding in mental deficiency institutions to the extent of more than 4,000 beds, while nearly the same number of mental defectives were awaiting admission. Mental hospitals show an aggregate overcrowding of 13.1% on the basis of recognized bed-space, and it is provisionally estimated that during the next ten years an additional 1,500 beds a year may be required to meet the increased numbers for whom accommodation must be provided. The Board points out that shortage of labour and materials and the priority necessarily accorded to housing have prevented almost entirely the provision of new accommodation for mental

¹Thirty-third Annual Report of the Board of Control for the Year 1946. Part I. London: H.M.S.O. 9d. net.

patients for several years past, and, with regard to mental defectives particularly, a partial breakdown in institutional provision is already causing difficulties. Equally serious is the shortage of nurses and particularly of female nurses, though in the view of the Board there has recently been some improvement in the general conditions of service in mental hospitals and in the accommodation provided for nurses.

MEDICAL BIRTHDAY HONOURS

The outstanding feature of the medical Birthday Honours, of which a full list appears in another column, is the barony conferred on Sir Alfred Webb-Johnson, Bt., surgeon to Queen Mary and President of the Royal College of Surgeons since 1941. Before his election as President of the College, Sir Alfred Webb-Johnson was known to combine the skill of a general surgeon with a remarkable capacity for administration. He was for some years the Dean of the Medical School of the Middlesex Hospital, and it was largely through his untiring efforts that funds were raised for the rebuilding of the hospital, which was opened in June, 1935, by the Duke of York. Although more than half the term of his presidency was during the dark days of war, Sir Alfred Webb-Johnson has probably done more for the Royal College of Surgeons than any of his predecessors. Under his guidance it has become a live and progressive institution for research and postgraduate teaching. Departments have been established and professorships endowed for anatomy and pathology; a research chair in ophthalmology has been instituted; practical teaching has been started in the College laboratories for postgraduate students seeking higher qualifications; under the new Charter, Faculties in dental surgery and anaesthetics have been established in the College; the R.C.S. now publishes its own *Annals*, the first birthday of which was celebrated last week. Sir Alfred's social gifts have found expression in the monthly dinners for Members and Fellows. Sir Alfred is the third practising surgeon to be elevated to the House of Lords, and future debates there should benefit much from his shrewd wisdom.

The youngest of the Royal Colleges is honoured in the knighthood conferred on Mr. William Gilliatt; and knight-hoods are conferred on Mr. John Newman Morris, Chairman of the National Council of the Australian Red Cross, and on Dr. David T. Rocyn-Jones for public services in South Wales. Air Vice-Marshal A. F. Rook, recently Consultant in Medicine to the Royal Air Force and now Director of Student Health Services at Cambridge, receives the K.B.E. The C.B. has been conferred on Surgeon Rear-Admiral O. D. Brownfield, Major-General J. J. Magner, and Dr. C. E. Good, and the C.M.G. on Dr. J. C. R. Buchanan, Director of Medical Services, Fiji, and on Dr. Percy Stocks, Chief Medical Statistician of the General Register Office. In congratulating these medical men on the honours bestowed on them the medical profession will also note with satisfaction the conferment of knighthood on the distinguished scientist, Charles Robert Harington, who is director of the National Institute for Medical Research at Mount Vernon, Hampstead.

SURGERY OF CONGENITAL HEART DISEASE

The last decade has seen some noteworthy advances in the technique of thoracic surgery. Since the report of the Committee of which Christie¹ was the chairman shows that subacute bacterial endocarditis could be cured by penicillin, more and more attention has been paid to the surgery of the heart and in particular to congenital heart disease. While there are innumerable variants of this condition, those compatible with life fall into four groups: patent ductus arteriosus, coarctation of the aorta, pulmonary stenosis, and septal defects. It was the frequency of the association of subacute bacterial endocarditis which stimulated surgeons to tackle the first of these groups. The success achieved provided further stimulus and led them to attempt operations which would have been considered quite impossible even before the last war.

The first successful ligation of the patent ductus was described by Gross and Hubbard,² and the first account of the operation in England were by Tubbs,³ who reported the recovery of 6 out of 9 cases of patients with subacute bacterial endocarditis. Tubbs told the International Conference of Physicians last year that he had operated on 3 cases and though some deaths had occurred they were mostly before penicillin was freely available. At the same meeting Crafoord stated that his mortality for the operation was 2%, and stressed that if recanalization was to be avoided it was necessary to discriminate carefully between those cases in which ligation would suffice and those in which division with its greater risks was necessary. Crafoord and Nylin⁴ described in 1945 their operation for the resection of aortic coarctation. In the course of experimental work on patent ductus arteriosus in dogs Crafoord noted the circulatory conditions which resulted after clamping the aorta at different levels and came to the conclusion that the surgical risks would not be too great. On the strength of these observations he took the risk in certain patients with a patent ductus of placing a clamp on the aorta above and below the point of entry of the duct in the aorta; the clamps were kept in position while he divided the duct and sutured the aorta; and in one patient it took 27 minutes. No significant disturbances were subsequently observed in the patients' internal organs or lower limbs.

Crafoord then decided to operate on a patient with coarctation and resect the stenosis; he performed the first of these operations⁵ on Oct. 19, 1944. Blalock⁶ had been considering the problem at about the same time and he performed an anastomosing operation in animals to improve the circulation peripheral to the stricture. This line of thought was continued by Blalock and Taussig⁷ in considering the third type of congenital heart disease—pulmonary stenosis. They thought that though the structure of the heart was grossly abnormal it might be possible in many instances to alter the course of the circulation in such a manner as to lessen the cyanosis and the resultant disability. To this end they tried several operations and eventually decided that the most satisfactory was that which effected an anastomosis between the subclavian branch of the innominate artery and the superior aspect of the pulmonary artery. The results of this operation have been dramatic, especially in children between the ages of 3 and

SURGERY OF CONGENITAL HEART DISEASE

9. In a series of 474 operations excellent results have been claimed in three-quarters and the mortality has not been high.

These results stimulated Brock to consider the problem further, and we published in the opening pages of last week's *Journal* an account of his brilliant work. He argued that the correct way to solve the problem of relief of valvular stenosis was by a direct attack on the valves. He pointed out that while in many cases of Fallot's tetralogy it was true that the stenosis was subvalvular, it was equally true that in many the stenosis was valvular. When a valvular stenosis was present it was diaphragmatic in nature and the fused valves were forced by the blood stream into a nipple-like projection with a tiny hole in its summit. The force of the blood pushed through this jet also caused dilatation of the pulmonary artery. Brock thought that the formation and structure of this stenosis showed that the condition was eminently suitable for relief by division and that a much larger opening could be made in a shorter time, in exactly the right place, than is possible with the Blalock operation, in which a long and tedious dissection is necessary to secure a systemic artery of adequate size. He therefore attempted the division of the valves at first under direct vision through a cardioscope passed straight down the left pulmonary artery. This gave him a good view of the valves, but the pulmonary artery being narrow the procedure placed too great a strain in the circulation and had to be abandoned. The experience gained, however, proved that it was possible to diagnose the presence of a valvular stenosis. The experience gained in the making an incision in the valve, and the relief of the stenosis, has been so far as the relief of the stenosis is concerned, the results in three cases are excellent. The operation will be performed in a further three cases. The post-operative course has been uneventful. Unfortunately this danger is known or perhaps prevented by dicoumarol.

What will be the surgery of the heart disease, and it is as 1925, attempted valve in a patient disease of the heart death in the patient possible that if the removed from that years longer.

restrain infection only by such organisms as staphylococci and not *Bact. coli*.

Serious infections may arise in various other possible ways when the infant has first to adapt itself to a world heavily populated with bacteria. It is uncertain which is the most probable when meningitis appears a week after birth with no obvious explanation such as meningococci. *Bact. coli* is much the commonest cause of meningitis during the first few weeks of life. The onset is usually within the first week, and prematurity has been disposed to it. The literature of the subject has been reviewed by K. J. Randall, who also describes six of his own cases, all fatal. In this series prematurity seems to have been a factor in two and prolonged labour in one. On the other hand, pneumonia, changes in addition to meningitis were seen only in two of the cases. One was normal. The onset in one of these was immediate and in the other about the sixth day. In one of these was between the fourth and seventh day. In one of these infants septicæmia was first detected by a leucocyte packed with ingested bacteria during the performance of a differential blood count. The condition of this child is illustrated, is quite unmistakable. In some of these infants the condition was apparently unrecognized during life, and its signs, which do not always include either fever or obvious coughing of the infant, can be misleading. *Bact. coli* is a Gram-negative bacillus, but effect in one case. Other life-endangering infections are streptomycin, other life-endangering infections for treatment with streptomycin, and we may hope that the next series will include information on the results of treatment.

THE SPREAD OF POLIOMYELITIS VIRUS

The mode of spread of an infectious disease is usually most readily revealed by investigation of cases during the early stages of an epidemic. This is particularly true of a disease such as poliomyelitis, in which cases of which are uncomplicated. In times when the disease is endemic the sources of infection are often not discovered. When an epidemic is at its height the infective agent is widely distributed and there are so many temporary carriers that the connexion between the cases may not be detected. In the early stages of an epidemic, when infection results in more overt cases than when the disease is endemic, and when the foci of infection are still localized, careful field work can sometimes reveal the lines of spread. An instance of this is afforded by Sweetnam's article on page 1172 of this issue. He describes the rather explosive epidemic of poliomyelitis in Eccles during the summer of 1947. Early in the outbreak it was possible to demonstrate direct or indirect contact between many of the cases. Later cases did not appear to be connected so directly. Infection spread across the town from west to east, a movement that corresponded with the west-to-east sequence of epidemic peaks of incidence in the contiguous urban areas of Irlam, Eccles, Salford, and Manchester. This type of spread has been noted in other epidemics where children with minor illnesses have been shown to play an important part in transmitting the disease. Sweetnam's investigations showed that about 20 such cases occurred for every case of paralysis and that they were more numerous in the neighbourhood of frank cases. These findings support his conception of a carrier epidemic preceding the appearance of paralytic cases.

MENINGITIS IN THE NEWBORN

On another page H. R. D. and J. T. B. are describing a case of *Bact. coli* meningitis in the newborn, which is of particular interest because of the origin of the condition is unusual. A clear, well-prolonged labour after rupture of the membranes, the onset of maternal pyelitis shortly after labour, the immediate onset of meningitis in the infant, and the finding of bronchopneumonia post mortem all point to an intrauterine infection via the amniotic fluid as the portal of infection being the lungs. This is an obvious route in such circumstances, and the danger must be borne in mind. As these authors suggest it may be an indication for chemotherapy, though the concentration of penicillin attainable in the foetal circulation would be sufficient to

¹ *Amer. J. Hyg.*, 1947, 45, 248.
² *British Medical Journal*, 1947, 2, 303.

A different pattern is seen in the epidemic among young soldiers in Catterick Camp studied by Dixon and reported in this issue at page 1175. There was no case-to-case contact and no two cases were in the same unit. Minor febrile illnesses in soldiers were not more numerous than during corresponding months in previous years and did not appear to be related to the spread of poliomyelitis. Dixon suggests that the infection may have been transmitted by soldiers with symptomless infections or whose illnesses were so mild that they did not seek medical advice. The healthy adult carrier has been thought able to spread infection from the time of Wiekman's studies onwards, and such carriers may have maintained the virus in the camp or introduced it from outside on return from leave. The explanations suggested for the Eccles epidemic and the cases at Catterick Camp are in accord, as explanations of the spread of poliomyelitis must be, with numerous demonstrations that frequency of cases is proportional to closeness of contact with a frank case of the disease. The recognition that patients may be infectious during the incubation period makes it possible to envisage contact as the main means of transmission. Zintek¹ has suggested, however, that the cases with nearly simultaneous onset in families are more probably due to exposure to an extra-human source of infection. In groups of cases with simultaneous onset it is necessary to consider the possibility of infection from some aliment contaminated with virus by flies or human carriers, but such a mode of spread would appear to be usually incidental to contact spread, just as streptococcal infections are sometimes transmitted by milk, although case-to-case spread is far more common. Precautions against the possible spread of the disease are touched on in a film, "Polio—Diagnosis and Management," produced for the Ministry of Health by the Crown Film Unit. It is the successor to the short one made last year² and was shown to a small audience last week. The film, which without tedium goes on for one hour, combines a first-class clinical demonstration with useful instruction on after-care and occupational therapy, and should prove of great value to general practitioners.

In another article in this issue (p. 1167) Field and Brierley refer to the spread of poliomyelitis virus within the body. The generally accepted view is that the virus spreads along nerve axons, but they suggest that some features of the disease are more readily explained by assuming that it spreads in the cerebrospinal fluid and that it may reach the central nervous system by lymphatic channels which they have demonstrated in the rabbit. In the body as in the community there may be several routes by which the virus spreads.

ADVERTISING OF PROPRIETARY MEDICINES

Successive statutes have forbidden the publication of advertisements offering treatments for certain diseases. The earliest was the Venereal Diseases Act, 1917, which made it an offence to advertise any preparation as a medicine for the prevention or cure or relief of such diseases. The Cancer Act, 1939, made it an offence to advertise any offer to prescribe remedies for the treatment of cancer. The Pharmacy and Medicines Act, 1941, similarly banned advertisements which implied that certain preparations might be used for the treatment of a number of diseases, including Bright's disease, diabetes, epilepsy, locomotor ataxia, and certain eye conditions. The same Act forbade publication of advertisements suggesting that any article might be used in a way calculated to produce misarrriage. In addition to these statutory injunctions a "British Code" has now been prepared with the approval

and support of the principal newspaper and advertising organizations, as well as of the Proprietary Association of Great Britain.

This code brings under a voluntary ban the advertising of remedies for a further fifty or so diseases. The diseases range from alopecia to varicose veins, from amenorrhoea to gastric or duodenal ulcer, from gallstones to obesity. They include structural or organic defects of eyes or ears and many skin diseases. Some of the categories are vague—"diseased ankles," "artery troubles," "cardiac symptoms"—but have been much used in lay press advertisements.

The movement towards a code of this kind first took shape twelve years ago when the Proprietary Association brought out, in agreement with the Newspaper Proprietors Association, a number of self-imposed restrictions, and a few years later, with the Newspaper Society joining in, further restrictions were added to the list in order to raise the general standard to the level of the highest adopted by any individual newspaper. The restrictions, of course, were obligatory only upon the members of the organization concerned.

In 1945 the Advertising Association took a hand; a committee was set up for the preparation of a common code, and the eventual result is the present document, which is supported by all the organizations above named, together with the Incorporated Society of British Advertisers, the Institute of Incorporated Practitioners in Advertising, and the Periodical Trade Press and Weekly Newspaper Proprietors Association. Thus the code has a triple backing—those owners of the proprietary preparations who belong to their trade association, the owners of newspapers, daily and weekly, and those who handle advertising matter. In addition to the ban on the offering of remedies for certain diseases guidance is given in other directions. Misleading and exaggerated claims must not be made. Appeals to fear are discountenanced. Such terms as "miraculous" or "magical" are out of court. Diagnosis or treatment by correspondence is banned. There must be no "money back" offers or prize competitions. Claims that a product will promote sexual virility are to be avoided. No reference must be made to a college, institute, clinic, or laboratory unless in fact such an establishment exists, and there must be no reference to doctors or hospitals unless such a reference can be substantiated by independent evidence and is properly used. The name "Dr." must not be attached to a product unless the product was so named before 1944.

Certainly the way of the patent medicine advertiser is made harder, for claims like those with which the British public has long been bemused will not appear in reputable newspapers or be handled by reputable advertising firms if the members of their respective associations follow the guidance given by this new code. Recognition should be made of the self-denial which these ordinances impose. It may be recalled that in 1912 a Select Committee was appointed to consider the question of the sale of patent and proprietary medicines, and that one of its recommendations was an amendment of the Indecent Advertisements Act, on lines suggested by the British Medical Association to include the total prohibition of the advertisement and sale (except the sale by doctor's order) of medicines purporting to cure a number of diseases, some of which were listed in the Pharmacy and Medicines Act twenty-seven years later, while others appear in this new code. Nothing further happened at that time, but since then, largely as a result of the action of the advertising profession and the public-spirited policy of enlightened newspapers, there has been a great improvement, which the new code will help to establish and carry further.

WEIGHT AND BLOOD PRESSURE

BY

R. A. MURRAY SCOTT, M.B.

Though information about the state of health of any section of the community is of particular value at the moment, few surveys of the nutrition of adults have been recorded. Some statistical records of haemoglobin levels are available, but little is known of the comparison, both in weight and in blood pressure, between age groups of people before the war and to-day.

A review has been made of the weights and blood pressures of the male members of an office staff spread over the North of England. The table shows the age distribution of the men examined in 1938-9, 1943, and 1946-7.

Age Distribution

Age Group	1938-9	1943	1946-7	
			Ex-Service	Non-Service
16-20	38	29		104

The weights were taken fully clothed, but as the examinations were evenly distributed through the years seasonal variation in the weight of clothes has been ignored. The measurements of blood pressure before the war were taken by one doctor, while those taken in 1943 and 1947 were measured on the same instrument by two doctors, one of whom examined over three-quarters of the men. The measurements made by these two doctors have been several times compared and found to be similar. In the 1938-9 group the average weight was 155 lb. (70.3 kg.). The average weight in 1943 fell to 151 lb. (68.5 kg.), and in 1946-7 it rose to 156 lb. (70.8 kg.). These averages do not in themselves give a true picture of what took place, as the proportion of men in the several age groups varied in each period—e.g., the larger number of examinations in 1938-9 were in the 26-40-year groups, while in 1946-7 the largest group is 16-20 years.

A more detailed exposition of weights by age groups is shown in Graph 1. The average weight in pounds is plotted against

GRAPH 1.—Average weight according to age groups

five-year age groups. The number of men in each group can be seen from the above table. From the age of 21 to 40 the average weight in each 1946-7 group exceeds that in each comparable 1938-9 group, showing a most marked divergence of about 8½ lb. (3.8 kg.) at 26-30 years. The 16-20 age group is static in each period; so is the 41-50 group. In 1946-7, the 51-55 group is 5½ lb. (2.5 kg.) less than the 1938-9 counterpart.

Graph 2 shows the effect of splitting the 1946-7 series into ex-Service and non-Service components and leaving the 1938-9 series for comparison. This shows that from 21-35 years the ex-Service men give a higher average weight than the non-Service men, while the 36-40 group of non-Service men is higher than the ex-Service group. The number of men in each group is now too small to be completely significant, but the steady trend of ex-Service men in three consecutive age groups to be heavier than the non-Service men is suggestive. It is

interesting to note that of 52 men aged 46-50 years examined in 1943, the average chest measurement was 37 in. (92.5 cm.) and the waist 32½ in. (81.25 cm.), while of 52 men of this age group examined in 1947 the average chest measurement was the

GRAPH 2.—Average weight of ex-Service and non-Service men of the 1946-7 group compared with that of the 1938-9 group.

same, but the waist measurement was 1½ in. (3.75 cm.) greater. This can be compared with an increase in average weight of 7 lb. (3.2 kg.) of the 1947 group over that of 1943.

Graph 3 shows the rising lines of diastolic pressure of the increasing age groups of the three series of examinations. Through the whole of its length the 1938-9 line lies below those of 1943 and 1946-7. The 1943 line similarly lies above the other two. This grouping at once suggests that the war

GRAPH 3.—Average diastolic blood pressure.

strain of 1943, due to extra work and additional employment in A.R.P., fire-watching, and so on, coupled with the worries of bombing and the fear for relatives in the fighting line, caused a comparative rise of diastolic blood pressure at all ages. This increase has now fallen to a level roughly half-way between the wartime and pre-war levels. There is an interesting but unexplained dip in the 1938-9 and the 1946-7 lines at the 41-45-year group. Of more practical importance is the fact that the 46-55 groups of 1946-7 have a diastolic pressure averaging about 88 mm. Hg., which is some 5 mm. higher than that of the 1938-9 group.

Graph 4 records the average systolic pressures of the age groups. It shows positively the great average increase in pressure in those over 40 years in the wartime and post-war groups compared with pre-war. The post-war heights show

GRAPH 4.—Average systolic blood pressure.

little decrease on the 1943 range. The rise of average systolic pressure in the 21-25 group in 1946-7 compared with the 1938-9 group is thought to illustrate the nervousness of men at their first examination, as no rise occurs in the diastolic pressure.

Conclusions

Up to the age of 40 years the men examined in 1946-7 are on the average heavier than men of the same age in 1938-9. From 41 to 55 years there is little difference between the two periods.

The men between 21 and 35 years who have been in the Forces are on the average heavier than those who have not.

The average diastolic pressures of all 1946-7 age groups are above those of 1938-9, the maximum difference being 12 mm. Hg at 41-45 years.

The average systolic pressures of all 1946-7 age groups are above those of 1938-9, the maximum difference being 27 mm. Hg at 46-50 years.

The rise in blood pressure can be correlated with a recent increase in neurocirculatory disorders in the male staff over 50 years of age.

This sample survey of a section of the community is interesting and provides nutritional implications. Additional information of this type from other sections of the community would help to paint more clearly the picture of the health of the people of this country to-day. Perhaps it is available, but not published.

ROYAL SANITARY INSTITUTE CONGRESS INDUSTRIAL HEALTH DISCUSSIONS

A Health Congress was organized by the Royal Sanitary Institute at Harrogate from May 24 to 28. Delegates were present from several hundred municipal authorities and voluntary bodies, as well as from Government Departments, home and overseas. Dr. James Fenton and Dr. J. A. Ireland represented the British Medical Association. The Congress, over which Lord Inman presided, met in eight sections and at four special conferences. The president of the Conference of Medical Officers of Health was Dr. F. Hall, County Medical Officer, Lancashire. Dr. G. S. Wilson presided over the Section of Preventive Medicine and devoted his address to a description of the Public Health Laboratory Service, now established on a permanent footing under the National Health Service Act; on this subject he was followed by Dr. J. Greenwood Wilson and Dr. A. Leslie Banks. Dr. Andrew Topping presided over the Conference of Health Visitors, and urged, though with an awareness of the nursing shortage, that the health visitor should be a State-registered nurse.

Pneumoconiosis among Miners

One of the best sustained discussions in the Section of Hygiene in Industry, presided over by Prof. R. E. Lane, of the University of Manchester, was on the health of the coal-miner. Dr. J. B. Atkins, regional mines medical officer, Ministry of Fuel and Power, dealt with the problem of pneumoconiosis. In South Wales during the last two years there had been a steady improvement in incidence. In that area the problem had been so great as to strip the industry within three or four years of the best of its young man-power. By the end of 1945, 12,000 men, mainly skilled coal-face workers, out of a labour force of some 120,000, had been forced to leave the mines on account of this disease, thereby not only depleting the industry but seriously handicapping recruitment.

The general view was that the exceptionally high dust concentrations met with in South Wales, particularly in the mechanized mines before dust-suppression measures were taken, accounted for the wave of cases during recent years. Some concentrations were described by those who worked in them as being so thick that a man's lamp could not be seen at a distance of a few feet, and the choking effect was such that men frequently vomited their breakfast on starting work. The most effective attack on the problem had been made by ventilation, water infusion of the seam before mining, and the modification of mechanical mining to reduce the dust carried, for example, by wet boring and cutting and the incorporation of water sprays with pneumatic picks. Another line of investigation was by the finer analysis of jobs from the point of view of dust hazard. Regular x-ray examination of all men exposed would enable precautions to be taken when radiological signs of nodulation had developed, though Dr. Atkins pointed out that a single x-ray examination might be misleading if other clinical findings were not considered, because the appearance of x-ray changes due to dust might be masked by the development of focal emphysema. The first of a number of special light industry factories for the employment of men suffering from pneumoconiosis had recently been opened.

National Coal Board Medical Service

Dr. C. L. Cope, of the Scientific Department of the National Coal Board, described how research on pneumoconiosis was being actively pursued by the Medical Research Council unit at Cardiff, the team numbering nearly sixty. In this connexion reference should be made to the Goulstonian Lectures published in our last two issues by Dr. C. M. Fletcher, Director of the Pneumoconiosis Research Unit of the M.R.C.

Until the National Coal Board established an x-ray plant of its own, Dr. Cope continued, the contribution of the Scientific Department could only be the collection and co-ordination of information obtained from surveys and from records of dust concentrations. An advisory committee on nystagmus among miners which was formed originally by the British Colliery Owners Research Association was being actively maintained. Negotiations were proceeding for the appointment of a medical officer in the area of the small Kent coal-field to investigate miners' dermatitis. For some reason the incidence of dermatitis among miners in Kent was much higher than in any other part of the country.

A more difficult problem to tackle was the group of diseases not peculiar to miners. It was uncertain how miners' morbidity compared with that of the rest of the community. Chronic rheumatism was a good example of the type of condition on which more morbidity statistics were needed. It was held by some to be more common among miners.

Finally Dr. E. H. Capel, principal medical officer of the Board, discussed present and future arrangements. Under private ownership a few mines provided good medical services, but in general the industry lagged behind modern industries in this respect. Coal-mining was well known to be a dangerous occupation. During 1945 more than one miner out of every four sustained an accident or contracted an occupational disease necessitating more than three days' loss of work, a rate about seven times higher than that for industrial workers generally. During the past ten years the incidence of fatal accidents had fallen by about 30%, serious accidents had fallen slightly, but less serious accidents had risen by nearly 40%. Although the incidence of pneumoconiosis had fallen in South Wales since 1945, it had risen in other areas. Of other diseases, between 1,000 and 2,000 cases of nystagmus were certified annually; the incidence of occupational dermatitis was rising steadily, and chronic infections of the knee and elbow—the so-called "beat" diseases—remained at a high figure.

The medical service of the mines, as Dr. Capel saw it, would devote itself to selecting workers and assisting in their placement, controlling environmental conditions from the health point of view, and providing first treatment in accident and illness arising at work. One difficulty in organizing a medical service was that mines were small units. Of 956 mines, only 532 employed more than 500 men; 80 employed fewer than 100. If as a result of health measures absenteeism could be reduced from its figure of 12.5% last year to 11.5% it would mean an annual increase of about two million tons of coal.

Purity of Food

Several papers bearing on food inspection were read to the Congress. Mr. E. Dodsworth, chief sanitary inspector, Harrogate, discussed the adulteration of milk. He said that the Ministry of Health had suggested that out of every three samples of food and drink tested one should be of milk, milk being the ideal substance for the practice of adulteration. The familiar plea of defendants in milk cases that the appearance of the milk was due to the insufficient quantity and quality of the food given to the cows was contrary to the opinion of research workers hitherto, though worth re-examining. Mr. Dodsworth urged sharper penalties for offenders. The figures for adulteration remain obstinately high.

Ice-cream was also debated, and Mr. Morley Parry, chief sanitary inspector for Northampton, declared that owing mainly to the 1947 regulation which stated that all apparatus for the manufacture of ice-cream should be installed, maintained, and operated to the satisfaction of the local authority, the days of back-scullery manufacture of ice-cream were over. Mr. Parry was of opinion that there was no satisfactory equipment capable of complying with the regulations for heat treatment in their full form for those who manufactured less than

four gallons a day. Really adequate plant would raise the cost of ice-cream produced on such a small scale by 100 or 150%.

Epidemiology of Yellow Fever

In the Section of Tropical Hygiene, presided over by Dr. C. J. Hackitt, director of the Wellcome Museum of Medical Science, the epidemiology of yellow fever was the main subject for discussion. Dr. A. F. Mahaffy, director of medical research at the Colonial Office, said that such a study fell into two epochs, each of them initiated and made possible by an important discovery. The first was the demonstration that yellow fever was an insect-borne disease, transmitted by the mosquito *A. aegypti*, and the second the transmission of the disease to rhesus monkeys.

In Africa, Dr. Mahaffy said, there was a wide field of immunity to yellow fever, extending from the west coast through Central Africa into Uganda and the Anglo-Egyptian Sudan—a much wider distribution of immunity than could have been predicted from the history of the disease. He mentioned in particular the work done in Bwamba, in the extreme west of Uganda. Here evidence had been found of a man-to-man yellow fever cycle with *A. simpsoni* as the vector and a monkey-to-monkey cycle transmitted by various forest-dwelling mosquitoes, of which *A. africanus* was the most important. The evidence indicated that the disease was endemic in the monkeys of the forest and that it was able to maintain itself indefinitely in these animals. There was every reason to believe that in Bwamba yellow fever was essentially a disease of monkeys in no way dependent on the presence of human infection but introduced from time to time into the areas inhabited by man.

Thus, Dr. Mahaffy pointed out, it seemed that there were two distinct kinds of yellow fever epidemic occurring in two entirely different types of environment—one in urban centres, a disease of man transmitted by the domestic mosquito *A. aegypti*, the other associated with jungle or forest, a disease of the lower animals, transmitted by forest-dwelling mosquitoes. He emphasized that the difference between these types was wholly epidemiological, in every other respect the urban disease was identical with that which originated in the forest. He now believed that the forest disease was the original epidemiological type and that it was from this source that urban centres were invaded from time to time.

So far as the control of the urban disease was concerned, he method of choice was the extermination of the vector, *A. aegypti*. The control of forest vectors was a much more difficult, perhaps an impossible, task. The extermination of the reservoir of virus in the animals of the forest was impracticable and this source of infection remained a constant threat to any urban centre with which it was in continuous contact and in which the urban vector had not been eradicated, or at least brought under effective control. Vaccination against forest infection, however, was available, and was being indicated in the case of crews and passengers of air and steamship traffic operating between endemic and non-endemic regions.

Air-route Sanitation

Mr. C. B. Symes, entomologist to the Colonial Insecticides Committee, brought forward in the same Section a suggestion for Commonwealth air-route sanitation, namely, the creation of a high-level air-sanitation authority, a committee and executive with wide experience of health problems in the Tropics and elsewhere, whose duty it would be to inspect important airports and advise the local authority on the application of sanitary measures. It would concern itself also with the siting of new airports, the planning of medical-inspection rooms and quarantine buildings, and the sources and supplies of food for passengers and crews. Sanitary zones would be demarcated, based not on territorial boundaries but on the distribution of the main infections, and an adequate standard of sanitation for all main route airports would be established.

Investigations had shown that large numbers of insects of many groups, including those incriminated in spreading malaria, yellow fever, plague, and trypanosomiasis, were conveyed for long distances by aircraft and apparently suffered no ill-effects from changes of altitude and temperature. Of 200 species of

insects found in aircraft in Africa, the commonest were mosquitoes, including the vectors of malaria, and the two vectors and seven possible vectors of yellow fever. If insects could be adequately dealt with on and around airports and in aircraft the problem of insect-borne infections in relation to air travel would be reduced enormously.

Airport health control was also discussed by Dr. W. P. Cargill, deputy M.O.H., Southampton. His general conclusion was that the present quarantine procedure applied to aircraft coming to this country was a compromise between maximum protection for our own people and minimum interference with travel, and seemed to be satisfactory, provided full use was made of the protection afforded to travellers by artificial inoculation. Experience had shown that although the danger to this country from the introduction of exotic infectious disease by air travel was perhaps less than had been expected, the introduction of smallpox from the East was always possible. The other "convention" diseases were less to be feared as regards introduction, but passengers incubating smallpox had arrived in this country by air during each of the last three years. True, they were Service men, but as civilian air traffic expanded so would the risk increase.

HOSPITAL PLANNING AND METHOD

ROYAL COLLEGE OF NURSING CONFERENCE

A conference largely attended by matrons and nursing administrators was held at the Royal College of Nursing on May 31 and June 1 and 2. The plan was followed of having a number of opening addresses and then dividing into discussion groups. The main theme was modern planning, equipment, and method designed to improve the service to the patients.

Modern American Hospitals

Capt. J. E. Stone, consultant to King Edward's Hospital Fund, who has lately returned from a visit to American hospitals, gave some impressions he had gathered. One thing which struck him in the modern American hospital was the reception department—a large and pleasing entrance hall, a desk labelled "Information," a courteous white-gowned hostess who knew everything about the hospital, a lounge in which visitors could wait, and a gift or hospitality shop. Another feature was a beauty parlour for the nurses; in America a well-turned-out nurse is considered to have a therapeutic value for the patient. In general discussion the lack of a proper reception department in British hospitals was deplored. One suggestion was that every patient and visitor should receive a leaflet about the hospital, written in an intimate way—not a series of "do" and "don't's."

A point of controversy is whether nurses should serve meals. In American hospitals the dietitian is in charge of meals until they actually reach the bedside. An electrically heated trolley comes to the bed and also offers the patient some choice of dishes. The over-bed table is largely done away with, and a locker is provided which on pressing a button extends a table, and on pressing another button furnishes the patient with a reading-desk. Bedsteads are largely made of aluminium. The old institutional mattress is giving place to an interior spring or rubber mattress. Some discussion took place on the best distribution of beds in the ward. The parallel-to-the-wall system, largely adopted on the Continent, found a good deal of favour in the conference, as opposed to the usual system of alignment of beds with their heads to the wall.

Noise in Hospitals

Capt. Stone said that in large American hospitals the visual system for calls is being used in preference to the auditory system; in this country the visual system has been installed in the new Charing Cross Hospital. In one hospital of 800 beds with the auditory call system it was estimated that 47 calls through the loud speaker in every ward and corridor were made during an average day. In some hospitals in America and in at least two in this country a microphone system has been put in whereby the patient who wants the nurse can speak to her at a distance, and a promised development of this system is an intercommunicating telephone whereby the nurse can also

answer at a distance. Headphones for wireless are being discarded in American hospitals in favour of a "husher-phone"—a disk about 10 cm. in diameter—which is placed under the pillow so that the patient can lie and hear the programme and even the occupant of the next bed cannot hear a sound. Hospital doors can be a great source of noise; this can be abated by a wide single door, with a good check return and without a catch—a plan followed in Westminster Hospital. The elimination of metal gates for lifts in favour of automatic doors would do away with another source of noise; and a noise which can be very irritating to patients, the hanging of cups on metal hooks in the ward kitchen, can be overcome by the use of leather-covered or plastic hooks.

The lighting of wards was also discussed, and what was called strip lighting—apparently fluorescent lighting—found some favour, though it had some critics, one nursing sister remarking that with this lighting "you cannot make up your mind what colour the patient is." Fluorescent lighting was stated by Capt. Stone to be very popular in American hospitals, but some device for toning it down is used in the wards. In the discussion speakers preferred for lighting at night a low-level light which can be switched on by the bed, also an independent light on the locker or near by which can be used for clinical purposes as well.

Mr. Bevan on Postponement

The final session of the conference was addressed by the Minister of Health. Mr. Aneurin Bevan said that there had been suggestions that the new Health Service ought not to start on July 5 because of shortage of beds, of equipment, of health centres, of doctors, and of nurses. But it was "stupid nonsense" to talk of postponing the Act until they had got all they needed. Expectation would always exceed capacity. In any case if there was a shortage it was all the more reason for making a well-balanced use of the resources available. "If there is a shortage of doctors on July 5, when the cash relationship between doctor and patient will disappear, it is very much more important that the doctors who are in short supply should spend their time looking after patients who really need to be looked after than that they should be looking after a lot of hypochondriacs who can afford to pay."

So far as nurses were concerned Mr. Bevan considered that the National Health Service itself ought to be the best recruiting agency. The conditions of nurses had been improved during the last year or so, and they would be improved even more. For example, the superannuation scheme would follow them wherever they went, from hospital to hospital, a thing which did not obtain at present. As for health centres, of course we were going to have health centres, but not all at once. Housing was the most important of all health services; if he had to choose between building houses and building health centres his choice was for houses. If a mother could have her baby in a good modern house it was better for her than to be in a maternity home.

From the beginning he had been most anxious that the people who actually ran the Service should have a bigger and bigger share in the policies which governed it. Democracy was not in the putting of a cross opposite somebody's name once in five years, but in the dynamic participation of the citizen in the affairs of his own profession or service. With this in mind it had been arranged to put a nurse on each Regional Board, but the Regional Board was not the main administrative hospital unit; this was the Management Committee, and it was desired that the staff groups in every hospital should be so organized as to have direct access to that committee. Participation of the nurse at hospital, regional, and national level was provided for in this scheme. There would be a Nurses' Advisory Committee at the top under the Central Health Services Council which advised the Minister. These advisory councils were very important bodies with power to make recommendations. Mr. Bevan stressed the freedom of the nurse in the Service to work where she wished; there was no power of direction, though there might be a request to a nurse to go to a hospital where there was shortage of staff. The Regional Board could not dismiss a nurse over the Management Committee's head because she was unwilling to go to another hospital.

In conclusion Mr. Bevan said that much attention had been drawn to what we had not got, but sometimes it was a good thing to call attention to what we had got, and we had some-

thing in this country which was of priceless value—namely, the genius for combining State and voluntary activity. Here we had a great centralized health scheme organized by the Government and paid for by the State—it was extraordinarily difficult to convince people that there was no contributory basis, but that the Service was provided for everybody from the national exchequer—but the voluntary system would be still at work. The voluntary system would be found on the Regional Boards and the Management and House Committees. It was this compromise between State and voluntary activity which showed the peculiar genius of the British people, and thanks largely to this he predicted that in some years' time—not too far ahead—people would be coming from all parts of the world to this country to study a magnificent health system.

SCOTTISH HEALTH SERVICES COUNCIL

The Scottish Health Services Council has been set up under the National Health Service (Scotland) Act to advise the Secretary of State for Scotland on the Service. It has elected Sir Humphrey Broun Lindsay chairman and Prof. Sydney Smith vice-chairman. Dr. E. R. C. Walker, Scottish Secretary of the B.M.A., has been appointed joint secretary with Mr. T. D. Haddow, of the Department of Health for Scotland. The first meeting, which Mr. Woodburn attended, was held in Edinburgh on June 11. The following are the members of the Council:

Appointed until Dec. 31, 1949.—Lieut.-Col. J. C. Dundas, chairman, British Hospitals Association (Scottish branch); Prof. G. B. Fleming, visiting physician, Glasgow Sick Children's Hospital; Mr. J. M. Graham, consulting surgeon, Royal Infirmary, Edinburgh; Prof. Sir David Henderson, Professor of Psychiatry, Edinburgh University; Mr. James F. Henderson, dental practitioner; Miss C. M'N. Keachie; Dr. David M'Call, assistant resident secretary of the Pharmaceutical Society in Scotland; Dr. George MacFeat, chairman of Scottish Committee of B.M.A.; Prof. J. W. M'Nee, Regius Professor of Practice of Medicine, Glasgow; Mr. John Mann, Convener of Lanarkshire; Dr. W. D. D. Small, President of the Royal College of Physicians, Edinburgh.

Appointed until Dec. 31, 1950.—Dr. A. D. Briggs, medical superintendent, Stobhill Hospital, Glasgow; Sir Humphrey Broun Lindsay, Convener of East Lothian; Prof. D. F. Cappell, Professor of Pathology, Glasgow University; Dr. R. C. Scott Dow, examiner in dental surgery for Royal College of Surgeons, Edinburgh; Miss J. P. Ferlie, matron, Simpson Memorial Maternity Pavilion, Royal Infirmary, Edinburgh; Dr. G. Matthew Fyfe, Medical Officer of Health, Fife; Dr. J. R. Langmuir, chairman of Glasgow Local Medical Committee; Prof. J. R. Learmonth, Regius Professor of Surgery, Edinburgh University; Dr. I. H. Maciver, member of Northern Regional Hospital Board; Mr. William O'Neill; Capt. Joseph Steel, director of Crichton Royal Institution, Dumfries; Capt. J. P. Younger, Director of Stirling Royal Infirmary.

Appointed until Dec. 31, 1951.—Prof. Dugald Baird, Regius Professor of Midwifery, Aberdeen; Dr. W. G. Clark, Medical Officer of Health, Edinburgh; Mr. Alexander Cunningham, member of Stirling County Council; Mr. C. G. Drummond, pharmacist; Dr. Mary Esslemont, general practitioner in Aberdeen; Mr. W. F. Ferguson, secretary and treasurer of Royal Infirmary, Edinburgh; Miss E. G. Manners, matron, Glasgow Royal Infirmary; Dr. A. F. Wilkie Millar, general practitioner in Edinburgh; Mr. Thomas Rankin, consulting dental specialist to plastic and jaw injury units at Bangour and Ballochmyle; Dr. Ferguson Rodger, Medical Commissioner, General Board of Control for Scotland; Prof. Sydney Smith, Regius Professor of Forensic Medicine and Dean of Faculty of Medicine, Edinburgh University; Mr. James Young, Provost of Kirkcaldy.

BOARDS OF GOVERNORS OF TEACHING HOSPITALS

The Minister of Health has appointed the following chairmen and members of Boards of Governors of Teaching Hospitals:

United Newcastle-upon-Tyne Hospitals.—Mr. Norman Dakeyne Newall, O.B.E., J.P. (chairman), who is appointed for the period ending March 31, 1951.

Appointed for the period ending March 31, 1950: Dr. Robert Vivian Bradlaw; Alderman John Chapman; Mr. Edward Colgan; Mr. Edward Foyle Collingwood; Mr. Henry Harvey Evers, F.R.C.S.; Mr. Fred Burnand Fenwick; Prof. Ronald Bramble Green; Prof. Frederick John Nattrass; Mr. John Walmsley; Mr. Thomas Alexander Wright.

Appointed for the period ending March 31, 1951: Mr. William Allan; Viscount Allendale, C.B.E., M.C.; Alderman Peter Stron-

Hancock, O.B.E.; Mr. W. Stanley Mitcalfe, M.C.; Mr. Robert Muckle; Rt. Hon. Lord Eustace Percy; Viscountess Ridley, J.P.; Sir Walter Thompson, J.P.

Appointed for the period ending March 31, 1952: Dr. Thomas Henry Bates, J.P.; Mr. Norleigh Booth; Dr. Samuel Whately Davidson; Alderman N. Garrow, J.P.; Mr. John Gilmour, F.R.C.S.; Sir Mark Hodgson, O.B.E., J.P.; Mr. Walter Daglish Lockety, J.P.; Prof. James Calvert Spence, M.C.; Alderman Miss Margery Taylor, O.B.E., J.P.; Mr. Sam Usher

United Leeds Hospitals.—Sir George W Martin, K.B.E., J.P. (chairman), who is appointed for the period ending March 31, 1951.
Appointed for the period ending March 31, 1951.

David Beevers, J.P.; Prof. Andrew Moynihan Claye; Mr W. M. Jones; Miss Elinor Gertrude Lupton, J.P.; Prof. William MacAdam; Prof. Thomas Talmage Read; Dr John Elvin Rusby, M.C.; T.D.; Prof. Arnold Nixon Shummin.

Appointed for the period ending March 31, 1951 Prof. Digby Chamberlain; Mr. Marcus Robert Hollings. Mr Joseph Charles Hunter; Mr. William Wilson Powell; Rev. Canon Arthur Sirelton Reeve; Mr. L. Richmond, CBE; Mrs. I. Barbara Shaw; Mr. Richard Wheeler, J.P.; Alderman Joseph Wilkenson, J.P.

Appointed for the period ending March 31, 1952. Mr. James Walker Booth; Mr. John Franco Fattorini; Mr. Frederick J. Higginson; Dr. John Thornton Ingram; Dr. Bernard Mowat Jones, D.S.O.; Mr. Leslie Norman Pyrah, F.R.C.S.; Mr. Harold Abbot Ryott; Prof. Matthew John Stewart; Mr. Mark Whitlock.

United Sheffield Hospitals.—Mr. A. Ballard (chairman), who is appointed for the period ending March 31, 1951

Appointed for the period ending March 31, 1950 Alderman
Alfred Buxton, J.P.; Mr Edward Thornton Lemmon. Mr J
Madin, J.P.; Mr Percy Mally. Mr Arthur Ratcliffe Martin, Mr
James Irvine Orme M.B.E.; Mr Theophilus Pearson.
Dr. Henry Renwick Vickers. Mr Thomas Gilbert Sorby Prof.
Edward Johnson Wynn:

Appointed for the period ending March 31, 1961: Mr. James Victor Bibby, D.S.O.; Mr. M. John Briggs; Mr. Gladys Burton J.P.; Mr. John Lewis Ardern; Great F.R.C.S.Ed. M.C. Alarman Percy Judd; Dr. Balfour McKean; Mr. Frederick Marmont Osborn; Mr. Leslie Bingham; Patrick F.R.C.S.Ed. Mr. William Raymond Shirecliffe; Stephen; Mr. Gerald Francis Young.

Appointed for the period end 1 March 1982: Mr Frank Anthony Barker; Sir Basil Gibson, JP. Mr William James L. F.R.C.S.; Dr. John Gibb McCue, OBE TD. Peter George Lawrence Roberts; Prof. Charles Herbert Sutherland, A'Fellow Mrs. Grace Tebbutt; Mr John Wilford T. Jett, JP.

United Cambridge Hospital - Mr. I. R. K. S. (chairman), who is appointed for the period ending March 31, 1951

Appointed for the term ending March 31, 1956: Mrs. A. J. McClean Bidder; L. B. Brazz J. P. Mrs. E. L. H. N. M. George Hawkins, O. B. M. O. C. E. E. E. H. A. O. M. Ernest William Plump J. P. R. P. O. C. E. E. E. R. L. Dr. Claude Howard W. J.

Appointed for the period ending March 31, 1966: Mrs. E. Binfield; Mrs. Eleanor Margaret Curran; Mr. Walter Macdonald; Francis; Alderman Edward Thomas H. Linar; Mr. O. L. F.R.C.S.; Mr. Roger Henry Parker M.C. Alderman Mr. E. Winifred Parsons; Mr. Alfred Smith; Harold Winifred F.R.C.S. Rt. Hon. Henry Urmston, Whiston M.C.

Appointed for the period 1st January 1962 to 31st December 1962:

Oswald Chivers, CBE, Director, British Antarctic Survey, High Cross, Madingley Road, Cambridge CB3 0ET.

Dean; Mr. Percy French, Director, British Antarctic Survey, High Cross, Madingley Road, Cambridge CB3 0ET.

Mr. Sidney George Newman, M.A., C.B.E., F.R.C.S., Director, British Antarctic Survey, High Cross, Madingley Road, Cambridge CB3 0ET.

Mr. H. J. Pye, Mr. A. J. Shepherd, M.B.E., M.B. (P.), S.D. (P.), Director, British Antarctic Survey, High Cross, Madingley Road, Cambridge CB3 0ET.

Ernest Howard White, Director, British Antarctic Survey, High Cross, Madingley Road, Cambridge CB3 0ET.

United Oxford Hosp. - Mr. E. G. C. ... F.R.C.S.
(chairman), who is accompanied by ... M.B. ...

Appointed for the following: Mr. C. W. Carter; Mr. Arthur F. Smith; Mr. Percy G. Alderman Dr. Isabell. Dr. H. M. J. P. Dr. A. Freeman King; Mr. R. G. M. Dr. Ed. Mr. Leonard Vincent Murray; Miss R. Dr. Arthur Quinton Wells.

Appointed for the period ending March 22, 1917: Dr. Edward Miller Buzzard; Sir Henry C. Park, Arthur D. Brown Gardner; Mr. John J. Johnson, CBE; Mr. A. C. Williams, Henry Booth King; Mr. James Christopher Scott, FRCS; M. Edgar Alfred Semewin, J.P.; Mr. Ralph Francis S. S. OBE, TD.; Dr. Janet Marie Vaughan, OBE; Dr. John Christopher Wharton.

Appointed for the period ending March 31 1952 Mr. Leonard Bertie Guy Bellinger Prof. Sir Hugh Cairns Dr. Alexander Macdougall Cooke; Mr H A Goddard Mr Gilbert Ernest Cecil Holt, J.P.; Mr. William Robert Robson, J.P.; Mr. John Thomson, J.D.; Alderman Lady Laidlaw, J.P. Prof. L.J. Wiggs.

United Bristol Hospitals.—Mr. Charles Cyril Clarke (chairman), who is appointed for the period ending March 31, 1951.

Appointed for the period ending March 31, 1950: Prof. Arthur Ivan Darling; Mr. Philip William Hort; Miss I. M. Lebb; Alderman John James Milten, J.P.; Sir Philip Robert Morris, C.B.E.; Mr. Anthony Gordon Palin, F.R.C.S.Ed.; Lady Sinclair; Mr. Herbert Bland Stokes; Miss Helen Strimer.

Appointed for the period ending March 31, 1951. Mr. Gilbert Charles Bennett, George Travers Biggs, DSO, Prof. Robert James Brocklehurst, Mr. G. T. Bullock, MBE, Prof. Albert Victor Neale, Rev. K. L. Parry, Dr. Sydney Kishaw Rigg, Mr. Harry Leslie Shepherd, F.R.C.O.G., Lady Wills, JP.

Appointed for the period ending March 31, 1952: Mr. George Alton Watson Allan; Mr. Egbert Caubrey, D.S.C., D.F.C., J.P.; Mr. William James Carter; Mr. Geoffrey Melvyn Fitzgibbon, F.R.C.S.; Dr. James Herbert Grove-Whire; Mr. John Angell James, F.R.C.S.; Prof. Robert Hughes Parry; Prof. Charles Bruce Perry; Mr. Herbert George Tanner

Unned Cardiff Hospitals—Mr. Gilbert David Shepherd, M.B.E., J.P. (chairman), who is appointed for the period ending March 31, 1951.

Appointed for the period ending March 31, 1950: Alderman Joseph Dicks; Mr. Douglas Benjamin Evan Foster, F.R.C.S.; Alderman James Griffiths, J.P.; Mr. Alex Samuel William Johnson, J.P.; Sir Ewen J. Maclean, T.D., J.P.; Mr. Samuel Ralph Marsh; Mr. Ernest Victor Rogers; Mr. Edward E. Tompkins, J.P.; Dr. Arthur Geroway Watkins.

Appointed for the period ending March 31, 1964: Alderman Sidney Jones, Mr. Robert Davies Owen, F.R.C.S.Ed. Alderman Oliver Cuthbert Purnell, C.B.E., J.P., Alderman Mr. Dorothy M. Rees, Alderman Richard Gruffydd Robinson, J.P., Prof. G. I. Stuchlik, Mr. Ernest Tear, J.P., Sir Ivor B. Thomas, J.P., Mr. James William Tudor Thomas, F.R.C.S., Alderman the Rev. William Degwel Thomas.

Appointed for the period ending March 31, 1982: Sr. Frederick J. Aibar, CBE, JP; Mrs. Helena Evans; Mr. Harold Finch; Prof. Jehro Gough; Mr. Charles James Handa, Jc.; Mr. Sidney Mitchell; Prof. Ralph M. F. Paken; Sr. W. Reardon-Smith, Bt.; JP; Dr. Thomas Roger Rees; Prof. Lambert Charles Rogers.

United Birmingham Hospital.—Mr. Stephen Francis Burman, M.B.E. (Lancaster), who is appointed to the post ending March 31, 1951.

Appointed for the period ending March 1, 1950: Mr. George Paul Alderman, Albert Frederick Brodner, M. D. Bulgin, Prof. Frank Cyril Power Cooke, Mr. John Fairfax Crowder, Alderman Mrs. Elsie May Farley, J.P. Prof. Humphrey Francis Humphreys, OBE, M.C. T.D. Mr. Raymond Edward Ponsley, M.C., Alderman Arthur James Stanley.

Approved for the period ending March 31, 1951

Onions, I.P.; Prof. Robert Platt.

United Liverpool Hospitals.—Sir Richard Harold Armstrong (chairman), who is appointed for the period ending March 31 1951.

Appointed for the period ending March 31, 1950: Mr. John P. Bibby; Prof. Henry Cohen, J.P.; Mr. Thomas Henry Herron; Miss Mary Jones, O.B.E.; Mr. Thomas Keeling, J.P.; Mr. George Leather, J.P.; Mr. Thomas McDonald; Mr. James Bagot Oldham, F.R.C.S. Dr. Prof. Hubert Horace Stones.

Appointed for the period ending March 31, 1951: Mrs. D. Barton M.B.E., J.P.; Mr. Albert Nicholas Denaro, M.B.E., J.P.; Mr.

Averill Doris Eills, M.B.E., J.P.; Prof. William Mowll Frazer, O.B.E.; Prof. Thomas Norman Arthur Jeffcoate; Alderman William John Lucas, J.P.; Mr. John Tertius Morrison, O.B.E., F.R.C.S.; Prof. Edwin Augustine Owen; Dr. Percy Henry Whitaker.

Appointed for the period ending March 31, 1952: Mr. Frederick Bidston; Mrs. Elizabeth M. Braddock, J.P., M.P.; Prof. Norman Brandon Capon; Dr. Robert Coope; Mr. A. Elliott, J.P.; Mr. Arthur Alexander Gemmell, M.C., F.R.C.S.Ed.; Mr. George Jennings; Dr. T. A. Jermy; Mr. James Frederick Mountford; Sir John Nicholson, Bt., C.I.E.; Mr. William Sutcliffe Rhodes, J.P.

MEDICAL BIRTHDAY HONOURS

The names of the following members of the medical profession were included in a Birthday Honours List published in *Supplements* to the *London Gazette* on June 10:

Barony

Sir ALFRED EDWARD WEBB-JOHNSON, Bt., K.C.V.O., C.B.E., D.S.O., T.D., M.B., Ch.B. Surgeon to H.M. Queen Mary. President of the Royal College of Surgeons of England since 1941.

K.B.E. (Military Division)

Air Vice-Marshal ALAN FILMER ROOK, C.B., O.B.E., F.R.C.P., D.P.H., R.A.F. Honorary Physician to the King. Consultant in Medicine to the Royal Air Force.

Knighthood

WILLIAM GILLIATT, C.V.O., M.D., M.S., F.R.C.P., F.R.C.S. President of the Royal College of Obstetricians and Gynaecologists.

JOHN NEWMAN MORRIS, C.M.G., M.B., B.S., F.R.A.C.S. Chairman of National Council of the Australian Red Cross. For outstanding services in Red Cross matters and voluntary hospital work in the State of Victoria.

DAVID THOMAS ROCYN-JONES, C.B.E., D.L., M.B., C.M., D.P.H., J.P. For public services in South Wales.

C.B. (Military Division)

Surgeon Rear-Admiral OWEN DEANE BROWNFIELD, O.B.E., M.B., B.S. Honorary Physician to the King.

Major-General JEREMIAH JOHN MAGNER, M.C., M.B., B.Ch., D.M.R., late Royal Army Medical Corps.

C.B. (Civil Division)

CHRISTOPHER FRANK GOOD, M.R.C.S., L.R.C.P. Principal Medical Officer, Insurance Medical Service, Ministry of Health.

C.M.G.

JOHN CECIL RANKIN BUCHANAN, M.D., F.R.C.P.Ed., D.T.M. and H., Colonial Medical Service. Director of Medical Services, Fiji, and Inspector-General, South Pacific Health Service.

PERCY SROCKS, M.D., F.R.C.P., D.P.H. Chief Medical Statistician, General Register Office.

C.B.E. (Military Division)

Surgeon Captain FREDRICK GEORGE HUNT, M.B., B.Ch., R.N. Air Commodore ERIC ALFRED LUMLEY, M.C., M.D., B.Ch., D.P.H., D.T.M. and H., R.A.F.

C.B.E. (Civil Division)

JOHN HENRY BIGGART, M.D., D.Sc. Professor of Pathology and Dean of the Faculty of Medicine, Queen's University, Belfast.

CHARLES SAMUEL CURTIS, M.D., Medical Director and Superintendent of Newfoundland Medical Service.

FRANK ARNOLD GUNASEKERA, O.B.E., M.R.C.S., L.R.C.P. Senator, formerly Officer Commanding, Ceylon Medical Corps.

EDWARD ROWLAND ALWORTH MEREWETHER, M.D., F.R.C.P., D.I.H. Senior Medical Inspector of Factories, Ministry of Labour and National Service.

JOHN ERNEST ALFRED UNDERWOOD, M.B., B.S., D.P.H. Principal Medical Officer, Ministry of Education.

O.B.E. (Civil Division)

WILLIAM DAVID BATHGATE, M.C., L.R.C.P. and S.Ed., Medical Superintendent, Hospital of the Edinburgh Medical Missionary Society, Nazareth, Palestine.

AGNES ELIZABETH LLOYD BENNETT, M.B.E., M.D. For services as medical practitioner in Wellington.

JOHN ROBERT BLAZE, L.M.S., Senior Physician, General Hospital, Colombo.

PERCY LESLIE FOOTE, F.R.C.S.Ed., Medical Superintendent, Bute Hospital, New Zealand.

JAMES JOHN JOSEPH GIPALDI, M.D. Physician, King George V Hospital, Gibraltar.

CHARLES NORMAN GRIFFIN, M.B.E., M.D., Colonial Medical Service. Federal Senior Medical Officer, Leeward Islands.

WILLIAM ARTHUR EDWARD KARUNARATNE, M.D., Professor of Pathology, General Hospital, Colombo.

SHANKAR DHONDO KARVE, M.B., B.S. For public services in Kenya.

ROBERT KIRK, M.D., F.R.F.P.S., D.P.H., Bacteriologist, Sudan Medical Service.

Mrs. ELIZABETH JOSEPHINE LE SUEUR, M.B., B.Ch., D.P.H., D.T.M. and H., Lady Medical Officer, Sarawak.

EDOWO AWUNOR RENNER, M.B., Ch.B., Senior Medical Officer, Sierra Leone.

GEORGE FRANCIS THOMAS SAUNDERS, M.D., Colonial Medical Service. Senior Medical Officer, Gold Coast.

THOMAS EDMONDSTON SAXBY, F.R.F.P.S., J.P., Medical Practitioner, Unst, Shetland.

Honorary O.B.E. (Civil Division)

LAWRENCE MICHAEL EKEN RICHARD HENSHAW, M.B., Ch.B., D.T.M., Medical Officer, Nigeria.

M.B.E. (Civil Division)

SYBIL KATHLEEN BATLEY, M.R.C.S., L.R.C.P., Medical Superintendent, Church Missionary Society, Onitsha, Nigeria.

GEORGE ERIC WARNER LACEY, M.B., B.S. Admiralty Surgeon and Agent, Woolwich.

Knighthood for C. R. Harington, Ph.D., F.R.S.

The honour of knighthood was also conferred on Charles Robert Harington, Ph.D., F.R.S., Director of the National Institute for Medical Research.

TRAINING OF NURSES

The General Nursing Council for England and Wales has submitted to the Minister of Health a memorandum on the Report of the Working Party on the Recruitment and Training of Nurses (Sept. 13, 1947, p. 426). The Council advocates three years of training instead of the two years recommended by the Working Party, considering that it would be impossible to cover the suggested syllabus in the time. Candidates should undergo the G.N.C.'s test examination before entering the training school if they do not hold the requisite qualifications; they should have a comprehensive medical examination and also be interviewed by the matron. No candidate should start training before the age of 18. Student nurses should be on duty (including theoretical training) for not more than 96 hours a fortnight.

Discussing the wastage during training that the Working Party emphasized in its report, the Council considers that the statistics which the Working Party used are misleading because they relate largely to the war years, when many girls entered the profession to avoid being directed to other work. "Dislike of contact with sick people" is an important cause of wastage not discussed by the Working Party, and the G.N.C. points out that since June, 1947, this reason for discontinuing training has been returned by 63 out of 311 student nurses. Unfortunately it is discovered only after training has started. On the subject of discipline of student nurses, which was discussed at length by the Working Party and by the organizations that have commented on its report, the G.N.C. emphasizes that "discipline to a certain degree" is essential, but that the rules should be accepted and appreciated as necessary to the welfare and comfort of those living in the nurses' home.

In recent years student nurses have had to undertake work that would normally be performed by the domestic staff; the Council deprecates this and considers that students ought only to care for nursing equipment and do such domestic duties as are part of the training. It asks the Minister of Health, and through him the Minister of Labour, to help in the urgent recruitment of ward orderlies and domestics.

Seventeen delegates from Belgium, China, Eire, France, Holland, Switzerland, and Sweden, with a power of attorney from Finland and fifteen from this country, attended the meeting after the sixth annual conference of the British Pharmaceutical Students' Association to discuss the formation of a world federation of student pharmacists. Russia ignored the invitation. Five weeks before the meeting Czechoslovakia promised to send delegates; none arrived. Hungary, after agreeing to be present, wrote asking for an official invitation to allow delegates to get permits to leave the country. Nothing more was heard of them.

Reports of Societies

CO-OPERATION BETWEEN PHYSICIAN AND PSYCHIATRIST

Need for Team Work

A discussion on cooperation between the psychiatrist and the psychologist in psychosomatic medicine took place in the evening of the Section of Medical Psychology. Ronald S. Gellert, M.D., presented a paper on May 25.

Dr. MAURICE DAVIDSON, the expression "team work" is very popular in recent years. It is a sacrifice of immediate materialism and opportunism necessary to realize and maintain its great reputation essential to full understanding any branch of medicine. In discussing that event

The crystallization of Freud and of psychiatry as a idea of psychosomatic centuries. In the Se from their colleague was anxious to eluc and the necessary li trist alike in deah which their function days many patients symptoms for which be discovered were Yet they were none the round of hospit

This extreme evaluation is perhaps less prominent in its own right. The real problem is the operation between the two. Much excellent and valuable medical literature has been written which was confined to the field when it was encouraged by the faculty inherent in the accompanying card. The progressive polyarticular psychosomatic problem or prolonged mental state is a dormant tubercle.

In days gone

infant: The first step to a conscious

be in the developing mind, and then in process of time, when the character of the ulcer-prone individual was fully formed, the somatic would add itself to the psychic element.

Physicians and psychiatrists united were probably the best hope of a sick world. Man was carrying to-day an immense load of emotional disability. He was lamentably unable to manage his affairs, with his fears and guilts and hates and aggressions. He lived by outworn standards imposed upon him by his grandparents, and it was not surprising that he often found relief in psychosomatic illness.

Prickly Psychiatrists

Dr. J. S. RICHARDSON said that the realization that certain well recognized and frequently encountered diseases which had been accepted as organic since they were first described had in fact a largely psychological basis was comparatively new. The missionary spirit of some psychiatrists made them at times prickly companions, especially when their enthusiasm outran the limits of their subject and even of their capacity. He wondered how long it took psychiatrists to achieve success where success was achieved. And what about the cases that relapsed? The picture they had been given by Dr. James of the grumpy physician doling out his bottle of medicine and yet being followed by his patient for years was true, but how much less good was his treatment than that of the sympathetic gentleman tête-à-tête with the patient, using techniques which were dramatic and doubtless effective, and how vulnerable were these patients to influences which were outside any doctor's control.

The general physician's relationship to the psychiatrist was the same as to any other specialist. He would seek his help as he would that of the surgeon or neurologist. Some patients mistrusted specialists and feared that certain aspects of their cases were apt to be overlooked by them. There were those who resented the suggestion that they should attend the psychiatric department, or felt a sense of shame or failure when this was broached. There would be something wrong with a society which allowed an individual to accept too willingly a psychiatric basis for his complaints. These prejudices contained something of value and furnished an additional reason why the physician should be as competent as possible to deal with such cases himself. He hoped the term "psychosomatic medicine" would fall into disuse, and that the physician and psychiatrist would come to use the word "medicine" in the same sense.

General Discussion

Dr. NOEL HARRIS said that the study of psychology should be incumbent on all who took up medicine, just as much as the study of anatomy and physiology. It was unfortunate that psychology had been thought of too much in the past in connexion with the study of psychiatry alone. Dr. RALPH NOBLE said that the psychiatrist, who of course had been trained as a physician, did examine his patient physically. As to how long it took the psychiatrist to achieve success, the best estimate was obtained by observing the cases treated in the wards of general hospitals by psychiatrists. In this country there were very few hospitals which had beds allocated to properly trained psychiatrists, but in America every good hospital had such beds. Not all patients needed a long treatment to get results by the usual methods now in vogue.

Dr. J. B. MURRAY said that the explanation of the majority of psychosomatic manifestations could be found if one chose to look to one's methods of history-taking and examination of the patient. Dr. DAVID SHAW considered that nothing could be more conducive to keeping the two Sections further apart than the suggestion that every physician should have a training analysis. More emphasis ought to be placed on the need for making psychiatrists better general physicians than for making physicians analytically minded.

Dr. J. RICKMAN said that the first tool of research was history-taking, and the first thing to be considered in taking a history was the cause which had brought about the illness. The technique for getting a fairly satisfactory psychosomatic history was to listen to the patient. If the psychiatrist pulled a lot of information out of the patient, he must give back to his patient—the doctor-patient relationship being a two-way traffic—something of what he had taken out. The patient

would understand better, if he was allowed to talk, how he came to be in the position in which he was, and the psychiatrist must be willing to tolerate information which at that time he felt to be irrelevant. The capacity to listen to a patient in suffering was the only way by which the physician would begin to see the patient completely as a live person. Dr. CECILY HINGSTON and Dr. MARGARET LOWENFELD spoke of the importance of child psychiatry, the latter deploring the lack of co-operation between the physician and psychiatrist in this respect.

Finally a surgeon present related a personal experience. Many years ago as a young man he had ambitions to be a huntsman, and particularly to wear a brown tail-coat and canary yellow breeches, but a fall from his horse and a severe injury to his back put a stop to his career in that direction. He made a good recovery and had enjoyed excellent health, but a few days before that meeting, in the high street of Billericay, he saw the hunt pass through, headed by a lady wearing a brown tail-coat and canary yellow breeches, whereupon he was immediately seized with excruciating pains in the back, which continued for the whole of that day. At night he took an aspirin and applied a hot-water bottle, and next morning the pain had completely gone. Ought he to have been analysed?

THE GREEN MONKEYS OF ST. KITTS

Dental Instability

An interesting piece of special dental research was brought to the attention of the Odontological Section of the Royal Society of Medicine on May 24 by Sir FRANK COLYER, when he demonstrated in the museum of the Royal College of Surgeons the dental condition of the green monkeys of St. Kitts. It is well known, of course, that New World monkeys differ from Old World monkeys; apart from other anatomical variations, New World monkeys have three bicuspid or premolar teeth on each side, both in the upper and lower jaw, whereas the Old World monkeys have only two. But the green monkeys of St. Kitts (*Cercopithecus aethiops sabaeus*), very small animals, exhibit a great capacity for dental variation, the result doubtless of environment, though to what extent a hereditary factor may also be implicated does not seem to be known.

Sir Frank Colyer has succeeded in obtaining a considerable number of the skulls of these monkeys, which reveal a frequency of dental variation three or four times as great as a numerically comparable group of African monkeys. The variations include, in one example, a supernumerary tooth posterior to the mandibular right molar; in another, an abnormal position of the maxillary incisors; in others again, rotation of the right maxillary second premolar and the mandibular third molar, and also projection of the first incisors and inward displacement of the second premolars. The third molar normally has three well-developed and separated roots, but these roots were shown in some of these examples to be in various stages of fusion. Evidence of caries of the right maxillary third molar was shown in one instance.

These animals are apparently in a state of dental instability, a state which alternates with dental constancy in various species. As for the cause of these numerical and positional variations the sugar cane in this West Indian island obviously suggests itself. The monkeys have a habit of tugging at the sugar cane the wear being mainly on the premolars. How far has this habit modified dental structure and produced anomalies? Whatever the explanation, this study has resulted in a further valuable addition to the priceless odontological collection at Lincoln's Inn Fields, which owes so much to Sir Frank Colyer's painstaking enthusiasm.

A school for the treatment and education of Scottish children suffering from cerebral palsy will be established this year in Edinburgh by the Scottish Council for the Care of Spastics. The Scottish branch of the British Red Cross Society is providing financial support, and it has bought for the Council a house in the Murrayfield district of Edinburgh. It is hoped to provide a home where parents can stay while learning how to care for their children. Research and the training of specialists will also be carried out. Dr. A. M. Fraser, Honorary Secretary of the Council, initiated the Scottish plan.

Correspondence

The Red Cross and St. John during War

Sir,—At the request of the Army Council and, subsequently, of the War Office and the Ministry of Health, the Joint War Organization of the British Red Cross Society and the Order of St. John opened during the war years some 250 establishments in England and Wales. These comprised convalescent hospitals, auxiliary hospitals, convalescent homes and residential nurseries. Many establishments providing simple convalescent amenities became hospitals organized for curative and rehabilitative treatments. Well over half a million patients passed through these hospitals and homes. They included officers and men of the British, Dominion, Indian and Allied Forces, and members of the Women's Auxiliary Services. Civilians injured by air attack, infants to 5 years of age and children from that age to 14 all in some way victims of the war.

Of the value of these establishments, Lieut.-Gen. Sir Alexander Hood, D.G. A.M.S., wrote: "No praise can be too high for the services rendered to the Army by the Hospitals and Medical Services Department of the War Organization which has provided care and comfort for thousands of officers and men and done so much for their restoration to normal health and strength." The Ministers of Health also expressed appreciation. Mr. Wilson, describing their assistance as invaluable, said, "But for the willing help given at all times by the auxiliary hospitals the work of the Emergency Hospital Scheme could not have proceeded so smoothly." Mr. Aneurin Bevan described them as "a department not only for the soldiers but also to men and women of other Services and to a certain extent, to civilians. Not only that, he added, but it has been too great for workers in the hospitals to be able to do a good job and well-being of the patients and to keep a great deal of very willing voluntary service is rendered."

A number of these homes were destroyed at the end of the war. The Government, under the direction of the Hon. Mr. St. John and Red Cross, have been opening them and its doors on July 4, and it is a great privilege and opportunity of expressing our thanks and appreciation to all those who made possible the healing and restoration of the homes of the poor. For Horder and Sir Alfred W. Horder, M.D., and the Medical Department, who have been working to restore the homes, and who gave so much to express on behalf and sincere thanks —

Where Are We Going

SIR,—My article on this subject in the *Journal* has brought me a large number of letters from all parts of Great Britain and also from Norway, Canada and the U.S.A. All my correspondents express full agreement with the views set forth at the prospect before us. Many address me for their own experience in support of my case and have asked for reprints for distribution among their friends. I have suggested that I should express my thanks for the book.

The only discordant note is coming from the medical photographers, whom I have worried a little. The photographers. My expression, "The Editors' Private Opinion." Dr. Peter Hansell (April 19, p. 618) says, "I am sorry. If plain English puzzles him, he is not fit to be asked to explain anything to him. My remarks about P. S. and T. Thomson, and Hopkins he thinks false. I assure him they were written in deadly earnest." R. G. W. Ollerenshaw (March 27, p. 618) is aggrieved that "the medical photographers at their word and assent have not meant what they say."

Of course advances in photographic art should be used for the benefit of health. No one wants to use cracked or faded slides. No one wants to do it the hard way when there is an easier, though some can achieve better results by the cheaper way than others can by the more expensive. It is all a matter of proportion. Medical photography must be subsidiary to medicine, not the reverse which is what the extravagant demands of at least some medical photographers threaten.

If photographs are intended for books the cost is usually passed on to the purchaser. Sometimes the author sells at a loss, hoping to recoup himself by increased private practice, greater prospects of promotion or merely admiration, glory, or pride in achievement. In such cases the cost comes out of his own pocket. When photographs are produced by commercial firms the directors and share-holders can be expected to see that so far as they are concerned there is a profit either direct or indirect.

Expenditure on medical photography in the U.S. is confined only in so far as the outlay may be directed toward an improvement in medical practice, resulting eventually in a diminution in the incidence and extent of disease. It is not justified if used for the personal gratification of those whose clinical achievements are thereby facilitated.

Some may believe that medical progress is an ever-
winding. The result of disease and of the past failure
are the other manifestations of nature's ever-
more. Some possess of in the past, the
of the elements. Should the, to the
of metaphysics must carry
of the, they can only be
of the, that there is within
and artistic perception—I am

6-22-66

Mr. ROBERTS.

Hearing-aids in New Zealand

SRK - The motion "Dec 6/44" is dated concerning the research work carried out by the New Zealand Institute of Medical Research Council. The motion is presented by the Government and often pointed out in the quality, safety and battery of the research training aids, the New Zealand League for the Hard of Hearing in 1940 requested the help of the New Zealand Standards Institute, a department of the Ministry of Industries and Commerce. The first motion of electro-mechanicians and other manufacturers, vendors and manufacturers of the New Zealand Security Department, and the League was called in that year.

I would like first Standard Specification in 1940. This was followed by several subsequent meetings, and in October, 1947, the New Zealand Standard Specification 266 was issued under the authority of the Minister for Industries and Commerce. Hearing-aid companies conforming with the specification and issued with the Government guarantee as to quality service and battery running time were entitled to bear the New Zealand Standards Mark. This was ignored by the vendors of imported aids, which, apart from minor differences, were designed to take batteries of special shape to fit only their own aids.

The Government, having announced its policy of issuing free or subsidized hearing-aids, had an investigation made by the Minister of Finance, which noted the unduly high prices charged for imported hearing-aids. These on examination were all proved to have their essential components—viz., microphones, amplifying valves, and crystal earphones—made by firms in America who held world patents over them. These firms did not make or sell hearing-aids but supplied the essential components to manufacturing vendors or allowed them to construct under licence, who architected them together on principles well known to acoustical science.

The Government called for tenders and accepted one called the "Universal" hearing-aid, which complies with the New Zealand Standard Specification and gives the specification guarantee for maintenance, service, and battery running costs for twelve months.

The Harvard Psycho-Acoustical Committee in its preliminary report on the selection of hearing-aids (*Laryngoscope*, 1946, 56, 81) drew attention to the fact that all valve-model aids made by reputable firms were of equal efficiency. Their design objective differs only in minor matters from the New Zealand Standard Specification 486. The New Zealand Universal model is bought by the Government at £15, inclusive of the crystal earphone with a sensitivity of 5 bars per volt, and an individually moulded ear-canal insert, batteries, battery containers, instruction booklet, carton, a guarantee of twelve months for service, and an estimate of yearly battery costs when the aid is used for six hours a day.

The Universal aid contractors also supplied special types of aids for cases where direct-insertion ear moulds cannot be used or are inadvisable, bone-conduction aids where required (about one case in a hundred), and special high-power aids of wearable type for cases of very severe loss giving high undistorted output for higher than usual speech "inputs." By means of a Universal battery holder, different sizes and weights of B batteries can be used. Two sizes of A battery or torch cells C or D can be used. This provides the necessary compromise between size, weight, and operating costs.

The Government then authorized the establishment of hearing-aids clinics at public hospitals to issue, under a qualified staff, free aids to all persons irrespective of age who had an average loss of 35 decibels over the frequencies of 512 to 4,096 inclusive. At the clinics, if the patient wants another aid from any outside firm, it has to be passed by the clinic officers, must carry the New Zealand Standard Mark, and give the written guarantee as to quality, maintenance, and battery costs if the aid is run for six hours a day. This brought to bay and severely limited the activities of vendors whose advertisements and previous disregard of the Standard Specification were tinged with callous disregard for the welfare of the hard of hearing. The distribution costs were claimed by vendors to be 100% to 150% of the wholesale price. This has been eliminated in distribution by hospital clinics. The cost of the latter is offset by the civil rehabilitation of many persons who were socially and economically depressed.

In the annotation is the statement, "It is, however, necessary to stress that many of the deaf included in this number (half a million in Britain) belong to the higher age groups. In them deafness is often due to senile and other degeneration of the internal ear, and so can seldom be satisfactorily corrected by electrical hearing-aids." We also thought so, but have been surprised at the very few who cannot be helped. We have also been surprised at the number of hard of hearing who had not contacted the various branches of the League. At the Auckland clinic, which started on Nov. 1, 1947, of the first 258 applicants for free aids the ages varied from 20 to 90 years. The greatest number were in the age group of 40 to 70 years. Their average hearing loss was 69 decibels.

In general, they had not had a hearing-aid because of their prohibitive costs, or have been dissatisfied with their efficiency, or have been unable to bear the expense of maintenance and battery supply. Most of them have been badly advised or given a hopeless outlook. Above all, they avoided the constant strain of trying to understand or get the context of what the speaker was saying. They have resigned themselves to practical seclusion, and withdrawn from group conversation lest they disclose their infirmity. The fact that they were in the main the first applicants for aids shows the urgency of their plea for help. In the first six hundred issued they form a mass that shows a correlated national tragedy and a hitherto lost legion.

For testing the hearing the clinic has a room that is reasonably sound-proof, and a Western Electric 6A audiometer. The League sound-proof room has an audiometer of local make which is also periodically calibrated and gives similar readings to the Western Electric. The presence of a supervising acoustical engineer has greatly contributed to the smooth running of the department. There are six distribution clinics in the Dominion and others are in the process of being set up. Over 90% of the patients have taken the Universal aid. Their delight in its efficiency is very gratifying. The other 10% have amongst them some persons who were unaware of the quality of the Government aid and were induced to give the £15 subsidy to the vendors and pay up to £30 additional money.

Determined efforts are being made by practically all hearing-aid manufacturers to produce small aids with the batteries contained in the amplifying case. This type of construction increases the battery costs to a level of £20 to £36 per annum. The smaller the aid the greater the reduction of safety factors. The New Zealand specification calls for an adaptor to be fitted to these single-pack aids, so that if the increased running costs are disclosed after use the ordinary battery pack can be coupled on to give smaller operating costs and more power if desired by the user.

Our great satisfaction is the practical elimination of the aids of some vendors whose meretricious advertisements delude the unwary, and whose disregard for service and battery supply was a source of disappointment and loss to many.—I am, etc.,

JAS. HARDIE NEIL,
President of the New Zealand League
for the Hard of Hearing.

Medical Photography

SIR,—Dr. R. G. W. Ollershaw (May 22, p. 1001) is sceptical of the opinions expressed in my letter (May 1, p. 855). Unlike him I prefer to express my scepticism in English; it is understood by so many more colleagues. Surely photography is not the only section of art which has not made any material progress during the past 40 years, except in the direction I indicated and as the result of advances in non-visible radiations.

Dr. Ollershaw says, "The great bulk of the pictorial work is mediocre," with which I agree, but when he follows with the statement, "Blaming the editorial boards will not help if the material is not good in the first place," I cannot agree. I believe it would help if it ensured efficient representation on those boards, for then that which was not good or accurately described would not be published—a real advance. It is better for the journal and the contributors if quality rather than prejudice decide acceptance.

He suggests that I am being unfair by withholding the name of the hospital whose figures I quoted. Had I felt that they did not contribute point to my argument I should not have used the figures, and I preferred not to give the name lest it be considered that their use was dictated by bias, for I had put up a carefully reasoned but unsuccessful protest against an ultra-modern hospital—the Accident Hospital, Birmingham—being run without a radiologist.

I do not consider that either of the two reasons quoted by Dr. Ollershaw are adequate excuse for the exorbitant demands of which he approves. He states, "The photograph is free from any possibility of personal error, which may well change with the observer." I agree that the possibility of error may well change with the observer, but I hardly think that is what he wishes to imply. Does he really believe that the photograph is free from any possibility of personal error? Surely it is the thing which is not free from the possibilities of erroneous interpretation, for the only person who can accurately interpret the photographs of many specimens is he who prepares the specimens. Without his guidance many photographs are liable to multiple and varied interpretations. For instance, of the two photographs reproduced in the *Journal* of May 22 (p. 993) to illustrate the article on medical photography (good as they are and readily interpreted by the person who prepared them) it can be reasonably claimed that those of us who do not know the specimen consider it a puzzle to find in Fig. 2 a "cavity in which nerve was densely adherent." It certainly is not in the middle of the picture as the object which should at once attract attention.

Fortunately I have been able to secure, by the kindness of Lady Robertson, an album of medical photographs which was made up some 40 years ago for the late Sir John Robertson, and in spite of the age of the prints would submit these with confidence to any unbiased committee for judgment. Had Dr. Ollershaw examined publications which contain examples of these illustrations (see *British Medical Journal*, 1931, 1, 133, and *Brit. J. Radiol.*, 1941, n.s. 14, 79) he would not perhaps have cast the slur contained in his last paragraph. I may say that the author of a book, nearing completion in printing, on pathological conditions of food animals sought permission, even in this modern age, to use some of these and a selection of others to illustrate the book—thus lending support to the old saying, "What Manchester does to-day, Birmingham (with its motto "Forward") did 40 years ago."—I am, etc.,

Edgbaston, Birmingham.

JAMES F. BRAILSFORD.

Obstetric Emergency Service

SIR,—A previous correspondence in the *Journal* (Dec. 13, 1947, p. 976, and Dec. 27, 1947, p. 1055) has revealed a wide spread interest in the working of so-called "flying squads" for treating acute obstetrical emergencies in their homes. The experiences of the scheme which has been operating in London for the past ten years under the L.C.C. therefore may be worth recording. It was started in 1939 with the limited object of supplying essential treatment (especially blood transfusion) for acute obstetrical emergencies occurring in the home, which could not safely be moved to hospital. With the exception of two boroughs, which were served by a teaching hospital, the whole of London was covered by 11 L.C.C. hospitals, a clear

This situation is now entirely changed, and it is understood that the Services Committee of the Central Medical War Committee has had to consider new means of increasing the inflow

of G.D.O.s to the Services. The Medical Women's Federation wishes again to express its opinion that the newly qualified women doctors ought to take their share of the burden, and that they would provide a not inconsiderable contribution to the requirement. It is understood that a recommendation on these lines has been made by the Services Committee of the Central Medical War Committee to the Medical Priority Committee. This would involve legislation to render women doctors liable to National Service, but the principle at stake is so important and the immediate need so urgent that the Federation does not feel that this is an insuperable difficulty. It reaffirms the desire of women doctors to share fully all professional liabilities.—I am, etc.,

Bromley, Kent.

MARY F. LUCAS KEENE,
President, Medical Women's Federation.

Gastric Herpes Zoster

SIR.—The case of gastric herpes zoster described by Dr. R. V. Stone (May 8, p. 882) brings to mind a similar case which I attended five months ago. In this case, however, the haematemesis was slight.

The patient, a woman aged 58, had a fall on her left side in November, 1946, bruised her ribs, and developed arthritis of her left shoulder-joint. She was x-rayed early in November, 1947, as she had stiffness and limitation of movement of the left arm. Nothing was found apart from some arthritis of the left shoulder. Ribs and spine were normal. In December, 1947, she developed severe pain in the region of 9th and 10th ribs, radiating towards the epigastrium, associated with nausea and anorexia. A week later she developed a typical herpetic eruption and the following day vomited about 10 oz. of "coffee"-stained fluid.

She was seen by a surgeon, who took her into hospital for investigation as she had lost a considerable amount of weight and was complaining of a burning sensation over the epigastrium which was not relieved by alkalis, etc. She was also considerably dehydrated and looked ill. All investigations during her 21 days in hospital were negative. Barium meal revealed nothing abnormal. Fractional test meal showed complete achlorhydria. X rays of spine and ribs were normal, and urine was normal. The C.S.F. was not examined. A laparotomy was considered, but the patient would not consent to this and accordingly she left hospital in the middle of January, 1948. By this time the rash was fading, though the pain was still severe but intermittent. Her appetite gradually returned, the nausea disappeared, and by the end of February she was completely well apart from some post-herpetic neuralgia. I last saw her at the beginning of April, when she had gained 10 lb. in weight and was entirely free from symptoms.

An interesting point in this case was the fact that the lady's grandchild had had chicken-pox about three weeks before she developed her initial symptoms. I think the similarity between this case and that of Dr. Stone is most interesting.—I am, etc.,

Belfast

P. E. FITZPATRICK.

Nervous Disorders and Malnutrition

SIR.—Dr. H. S. Stannus in his paper "Disorders of the Nervous System Due to Malnutrition" (Feb. 21, p. 342) remarks that "considerable and new interest has been aroused in nutritional disorders of the nervous system as a result of their high incidence among prisoners of war in the Near and Far East." While malnutrition is undoubtedly of great importance in these manifestations, I want to raise another point. On comparing the reports about the health of returned prisoners of war and of inmates of concentration camps one finds that the syndromes were encountered only amongst the P.O.W.s detained in the East. Both groups were on an inadequate diet, and people in the concentration camps were even on starvation diet. Lipscomb¹ states that "clear-cut specific vitamin deficiency syndromes were strikingly absent." Rosencher² writes that in Dachau "avitaminoses were rare and disappeared rapidly." It seems significant that there was a great incidence of malaria, ankylostomiasis, amoebiasis, and other intestinal infections amongst the P.O.W.s in the East. Lipscomb asserts that in Belsen there was neither malaria nor amoebiasis, nor were these diseases common amongst the P.O.W.s detained on the Continent.

The main reason for the appearance of the nervous manifestations supposed to be due to malnutrition and to vitamin deficiencies amongst the P.O.W.s detained in the East can only be that these manifestations were precipitated by the prevalent infectious diseases like malaria, amoebiasis, and hookworm infections. This is in

accordance with modern views, which regard these diseases as disposing factors for deficiency diseases. These infections are known to cause anorexia and gastro-intestinal disturbances, and this results in a low calorie-intake and contribute to the malnutrition. Simultaneously there will also be poor absorption of the food due to the affection of the gastro-intestinal tract, especially in amoebiasis and ankylostomiasis, which cause loss of mucosal integrity. Last, all three diseases are known to cause hepatitis and affection of the liver, which in turn will lead to decreased utilization of the food.

However, there is another consequence of the involvement of the liver to be considered. Experimentally it has been confirmed that disease of the liver can cause brain lesions and damage to the nervous system. This is demonstrated in hepatico-lenticular degeneration, where derangement of the liver produces nervous changes and disturbances. The course of the disease is influenced by the diet. Homburger and Kozol³ write that "in the cases where exacerbations were related to periods of inadequate diet, remissions followed periods during which the patients had been taking high calorie diets relatively low in fat."

Interference with the metabolism of the host by invading parasites must also be considered. It is well known that the malarial plasmodium consumes glucose and oxygen. It has been established that (1) suspensions of parasites consume oxygen at a high rate much higher than does normal blood; and (2) the malarial parasite uses glucose—half of the proportion which is destroyed being converted into lactic acid and the other half being incompletely oxidized.⁴ Thus malarial infection might deprive the host of the glucose and oxygen which are needed for the metabolism of the brain which derives its energy solely by the metabolism of glucose.

I have seen the nervous disorders mainly during the hot season. This may be due to malaria and amoebiasis being prevalent during these seasons, but it may also be possible that during the hot season there is an increased metabolism and this will accentuate any nutritional deficiencies.—I am, etc.,

Chirala, India.

Scoliosis in School-children

SIR.—In 1942 my attention was drawn to scoliosis in the dorsal region caused by slight shortening of the one leg in a munition worker complaining of backache. There was neither history nor symptoms suggesting previous infantile paralysis or other disease, and she had attended and had various treatments at hospital, but it had never been noticed that the one leg was about half an inch shorter than the other. This naturally caused tilting of the pelvis and a compensatory scoliosis higher up the spine. Her symptoms cleared with the raising of the heel by half an inch, and massage and exercises.

Since then, when examining school-children, I get them to bend down and try to touch their toes with knees stiff, so that when standing behind them, one can easily run one's finger along the spines of the vertebrae and note whether there is any scoliosis present. Occasionally one finds a lumbar curve with the muscles of the convex side slightly more prominent than on the opposite side, as if the bodies of the 2nd, 3rd, and 4th lumbar vertebrae were twisted a little on their vertical axis. If these children are turned round and examined from the front, it can be seen that the opposite shoulder drops and the pelvis is tilted, with one anterior superior spine higher than the other. Measurement of the legs, when lying, shows a difference in length of from 1/4 to 3/4 in. (usually about 1/2 in.), as taken from the anterior superior spine to the internal malleolus. There is generally no difference in the circumference of the thigh or calf, though in one girl the whole side of the body seemed slightly smaller. The girls are normally healthy and complain of no discomfort.

When I first see them they range from 9 to 12 years old, and in each set of new girls in the past 4 years there have been one or two cases; so that in the school at present I know of 6 cases, which works out at 1 1/2 to 2%. In 4 of the 6 girls the left is the shorter leg, the lumbar curve is convex to the left, and the right shoulder is dropped. With back exercises and the raising of the heel by the required amount (about 1/2 in.) much of the deformity disappears in time.

Another form of scoliosis is seen among the older girls, but this occurs higher up the spine, mostly in the lower dorsal region; it is combined with a twist of the bodies of the vertebrae which causes a projection of the posterior curve of the lower ribs on one side when they bend down to touch their toes. It is accompanied by dropping of the shoulder on the opposite side, and the syndrome invariably arises from the bad habit so many young people have of standing on one leg with the other knee bent. This gives a

The Natural Aid to
NUTRITION

WHEN the general nutrition of the body is below normal as a result of dietary errors or of debilitating diseases, the use of 'Ovaltine' is of greater and more lasting value than that of chemical stimulants. It adequately reinforces and renders safe the ordinary dietary; is a powerful source of energy and assists tissue regeneration.

A considerable measure of the value of 'Ovaltine' as a highly satisfactory accessory food and aid to nutrition is due to its constituents—milk, eggs, malt extract, cocoa and soya.

'Ovaltine' is not only highly nutritious, but really delightful to the taste and particularly easy of digestion.

efficient immunization

FOR THE WORLD'S

BABIES

Immunization against diphtheria has so diminished the incidence of that disease that world attention now focuses upon pertussis as a major cause of child mortality and disability. An alum-precipitated pertussis vaccine is acknowledged as the most efficient known means of stimulating immunity to whooping cough, and its combination with diphtheria toxoid in one immunological weapon has reduced dual prophylaxis

to a single course. To meet the need for protection among the infant population of the world, a series of three injections of Diphtheria-Pertussis Prophylactic Glaxo (0.5 cc., 0.5 cc., and 1 cc. at monthly intervals), begun at about six months of age, confers a high level of immunity during the period of life when the two diseases are most distressing and most lethal.

GLAXO

Diphtheria-Pertussis Prophylactic Glaxo

Each cc. of the 'Combined Prophylactic' contains at least 1/25 Diphtheria Prophylactic A.P.T. and 20,000 million H. Pertussis.

The
HECSON
SUPER ELASTIC TRUSS
for the Treatment of Hernia

Strap is fixed to Pad at A. Therefore greater pressure is exerted at B, when the strap is pulled tightly.

Where treatment of Hernia by surgical methods is undesirable for any reason, the HECSON super elastic truss can be confidently recommended. The Special Feature of the HECSON Truss is that the porineal or under strap is attached to the top of the pad instead of the lower margin as in the ordinary elastic or old spring truss. Thus it becomes part of the leverage mechanism for increasing the pressure of the pad at its base.

In the beginning the reaction to dicumarol takes place slowly, perhaps 48 hours, but after the 10-14 days' intermission a small dose of dicumarol (25 mg. to 50 mg.) may result in a profound alteration of prothrombin time, accelerated (24 hours) as compared with 48 hours for the initial doses: and the prothrombin time returns more rapidly to normal (24 or 48 hours

compared with 10-14 days). This small "re-educating" dose may be followed by 100 mg. every other day until the prothrombin time has lengthened to the desired extent. In spite of the objections of Dr. H. Lempert (Jan. 17, p. 125) and Dr. R. G. Macfarlane (*J. clin. Path.*, 1948, 1, 113), it is maintained that viper venom (the "stypven" of Messrs. Burroughs, Wellcome and Co., Ltd.), if calibrated before use, is a perfectly safe and reliable guide to the prothrombin time after dicoumarol treatment provided the technique is above reproach.—I am, etc.,

Epping, Essex.

FRANK MARSH.

Our Democracy

SIR.—I congratulate you upon your decision to give Dr. A. C. E. Breach (June 12, p. 1157) adequate space in which to deal with the anomalies that many of us feel exist at present in the effort of the R.B. to voice the views of the profession. Dr. Breach's analysis is thoughtful and factual and his suggested remedies call for close attention. But all this will take time, and time is just what we have not got if, as many of us think, we should bring order into the present confusion and stem the drift into *laissez-faire*.

What is the actual position to-day? We had two alternatives before us (and this whether we consider the progress of medicine, the best service for the public, or our own freedoms): either to get the present Act so amended that these things would be safe for a considerable period, or to give the Minister a blank cheque and be in perpetual doubt as to whether we could honour it—in other words, watch every Regulation with critical eyes for an indefinite time. In February we had no doubt that the first alternative was the proper one, and we said so. In April the hurried plebiscite, with its implication that the position had materially changed, and the *volte face* of the Council, which the Chairman was powerless to oppose, broke the all too tenuous thread which held us united; and in May, through the R.B., we chose the second alternative.

How, now, are we to clarify the position and regain our self-respect and the respect of the public? There is a large section of the profession which feels that these things should not be left in the hands of the men who, though they "have discharged their exacting and arduous duties" in a patient and conscientious way (Breach), yet have "taken the wrong turning." Confidence has been badly shaken. There are many doctors asking for guidance, not only for themselves but for their sons and daughters thinking of medicine as a vocation. To these are to be added many members of the public. There will shortly be a third group—men who will leave the Service they have too hastily joined out of fear and not conviction.

What is the best way of dealing with the situation? Will you allow me, Sir, to say through the medium of the *Journal* that I shall welcome the views of any of your readers sent to me privately? Such a step seems to me desirable before any action is taken in which I am concerned.—I am, etc.,

London, W. 1.

HORDER.

Rota of Pharmacies

SIR.—Dr. L. S. Woolf (May 22, p. 1006) draws attention yet again to a pressing problem. During my membership of the Hours of Service Subcommittee of the Middlesex Insurance Committee (shortly to be superseded) I drew upon myself considerable unpopularity and the open antagonism of the pharmaceutical members of the Committee, who were determined to perpetuate what was in effect a wartime practice of early closing. I pointed out that the pharmaceutical service was as integral a part of medical benefits as the doctors' service, and that, although something was paid to the doctors for emergency supply of drugs after hours, this was based on the old assumption that chemists would remain open during normal evening hours—say, till 8 p.m. in most cases.

The pharmacists' case was that they were bound by the Shop Hours Act as regards the sale of cosmetics, fancy goods, etc., and that it would not pay them to remain open solely for the purpose of dispensing. It was finally agreed that the rota system, which had been more honoured in the breach than the observance, should be properly implemented. A little improvement has taken place, but it is to be hoped that the new regulations will insist on an adequate pharmaceutical service in the evening. A woman should be able to obtain a sulphonamide after 6 p.m. even if she cannot get a lipstick.—I am, etc.,

M. MUNDY.

Remuneration in Rural Areas

SIR.—It fell to my lot to be the representative of the Rural Practices of Great Britain on the Association's Representative Committee which discussed the "shape of things to come" with the Minister of Health (then Mr. Ernest Brown) while the White Paper for the National Health Act was in preparation. I was also one of the two witnesses called to give evidence on behalf of rural practitioners before the Spens Committee. Not unnaturally, therefore, after reading the official leaflets describing the scheme, I am moved to make some comments on matters which seem to be of vital importance to country doctors.

Take first of all the main condition for granting the (unfortunately so christened) "basic salary"—the minimum number of patients. At this, in the words of one of Mr. George Robey's songs, "I'm not only surprised, I'm amazed!" For no distinction is made between the town doctor with all his patients within easy walking distance (over pavements) and the country doctor in a sparsely populated, extensive, and difficult district, with each patient an average of five miles away from him (and part of that five miles "o'er moor and fen, o'er crag and torrent wide"). As things stand, each alike, it seems, qualifies for "basic salary" on the same minimum of 500 patients. Surely, as a matter of plain common sense and equity the truly rural doctor should qualify on less than is stipulated for the town doctor.

It should be made quite clear also in what way the "inducement grants" to those who practise in difficult areas will be distributed and how much they will amount to. Without adequate inducement it will certainly be found that many experienced and fit country doctors in their fifties will turn from doctoring to farming—a very lucrative occupation just now.

The question of adequate mileage grants to rural doctors is another matter that needs very special consideration, because our car expenses are greatly increased by quite abnormal conditions, which are not likely to be remedied for a very long time. My own case is perhaps typical of many other colleagues'. I have to use two cars against the town doctor's one car. The roads I travel along are in a very poor state—and little wonder, for during the war this was a battle area, and heavy tanks, many hundreds of them over a long period, pounded over roads and lanes which were meant for horse traffic. Now repairs to these roads have been further hindered by the "axing" in the county of a large number of roadmen and the drastic curtailment of road maintenance and improvement schemes. The cars which I have to drive along these roads are respectively of 1937 and 1938 vintage because I cannot get a new car under present conditions of supply. Whereas it was my pre-war routine to change one car for a new car every year, the agents now tell me that if they can supply a new car in two or three years' time I shall be lucky. In the meantime repair bills mount up to alarming figures on each car annually—a factor which is not contemplated at all under any existing scheme of N.H.I. mileage grants. Neither is adequate allowance made for the time factor in country work, not only the time spent in motoring and walking to distant farms (I may walk often six or seven miles in a day), but also the time spent in driving ten or twelve miles to the nearest town for car repairs beyond village resources; for shopping, or to get to a cinema or concert. (One is entitled to one's recreations in the country as well as in the town.)

Then there is the rent of the branch surgeries and "houses of call" which are so essential in country areas; and there is the dispensing, for willy-nilly dispense we must if most of our patients are not to be saddled with great inconvenience or even real hardship. For instance, at one of the villages from which I mainly carry on my practice the nearest chemists are respectively eight, ten, and twelve miles distant, and the only form of public transport is a bus once a week to two of the towns. If I did not dispense at my branch surgery a messenger would have to be employed to get any medicines that were urgently needed; and the tariff is 10s. per journey by motor-cycle, £1 by a hired car.

Obviously doctors must dispense under conditions such as these, and the dispensing allowance should cover the cost of employing a dispenser as well as the cost of the drugs. Indeed, was not that the suggestion, or even the promise, made by Mr. Bevan in a Parliamentary reply soon after he took office? Unfortunately I have not the time nor the opportunity to delve into *Harisard* on this point, but I seem to have a very clear recollection that such a statement by him was duly reported in the *B.M.J.*'s "Notes in Parliament."

Lastly, there is the matter of telephone and postage expenses. These are very heavy in country practice at the present high rates I have, for instance, to rent two telephone installations and an extension. One of my neighbours maintains three. Each call to the nearest hospital costs 6d., and two or three such calls may have to be made to secure the admission of a panel patient. All the many local calls are on the same scale—and will multiply after July 5. The 2½d. postage stamp makes a big difference, too, in the costs of

sending necessary letters and tablets to patients, and there is the quite appreciable item of medicines sent by train and by bus. It is true that most patients would willingly reimburse these items, but it is quite impracticable to keep a note of the multitude of them—small payments individually, but very appreciable annually in their sum.

Such are some of the considerations that, I submit, should be borne in mind in assessing the remuneration of the rural doctor. Many of them were emphasized in my evidence to the Spens Committee. I hope that they may materialize as something more tangible than the elusive "rare and refreshing fruit" of Mr. Lloyd George's promises in 1911—or the receding mirage of health centres. Will the rural doctor get a "new deal" under this new Act? Or, in the words of my one-time sergeant-major (a ruthless castigator of super-optimists) is it just going to be "some bloody 'opes"?—I am, etc.,

Clynderwen, Penn.

E. R. ROLAND WILLIAMS.

* * Mr. Bevan said in the Committee stage of the N.H.S. Bill (*Hansard*, June 25, 1946) "arrangements will be made in rural areas for doctors to provide medicines." The Secretary of the B.M.A. writes: "The Association has not yet discussed with the Ministry of Health the doctors' remuneration for dispensing under the National Health Service. It is awaiting a proposal from the Ministry, and the Ministry is not in a position to make one until it has dealt with the chemists' remuneration." The Association is, however, alive to the position in which rural practitioners will find themselves inasmuch as the persons for whom they will be required to dispense will be fewer in number, though they will still have to employ a dispenser. The Ministry has been informed and recognizes that this is one of the points which will have to be taken into consideration.—Ed., B.M.J.

Partnership Agreements

SIR.—A great deal of correspondence dealing with the multitude of aspects of the N.H.S. Bill affects the individual practitioner or section of the profession, and has appeared in the columns of the *B.M.J.* No direct exchange of views has been made concerning existing partnership agreements when the N.H.S. comes into operation on July 5. We are informed through the medical and national press that the question is under consideration by a legal tribunal.

The tribunal was formed over a month ago and no report have been forthcoming. This most important question affecting a large number of medical practitioners in practice have been neglected. Announcements containing such phrases as "40 doctors will be free to work on a partnership basis" leave one in doubt as to whether this applies to existing as well as future partnership agreements. Since, no conclusion could be reached and announced on the existing proposal, the advent of the N.H.S. quickly approaches and surely we are entitled to know our position as partners before the grand upheaval on July 5.—I am, etc.,

Manchester.

M. J. O'DONNELL.

Health Centres

SIR.—In your leading article entitled "What We Have Gained" (May 15 p. 47) I should like to contribute when referring to the building of health centres. Building materials and labour will be more usefully employed in providing new houses. In many parts of Great Britain this may be true in the industrial areas I feel that the building of health centres is most urgent. Practically all the doctors' houses have quite small surgery accommodation. The war programs were designed for private practice and during the winter months have been only just able to cater for the increased numbers attending for N.H.I. certificates. It is certain that with free medical attention there will be a considerable increase in the number of women and children attending. During the winter months there will be a gross deficiency in accommodation. It is apparent to anyone working on the spot that in the winter there will be queues outside almost every doctor's house; women and children will be refused admission; they will either have to wait outside in rain or snow, or return home and hope to gain admission at a later date. Mr. Bevan has produced

the regulation for the Service without any provisions. He has set up the machinery, but appears to have no intention of providing a roof.

I submit, Sir, that the provision of health centres, whether temporary or permanent, must be given urgent consideration. This Government is pledged to help the working classes. Unless it provides accommodation the patients in these areas will suffer hardships in the not far distant future. During the war whole air-fields were rapidly erected. Surely enough materials could be obtained in times of peace. Each health centre would cater for the needs of several thousand people. It has been stated that there is a shortage of trained staff. For attendance on "sick parades" and simple dressings any woman who has had experience as a nursing orderly in H.M. Forces or as a V.A.D. in hospital would be suitable.

I feel that the Minister of Health could encourage the local authorities to proceed in thickly populated areas. He is reluctant because it will mean an increase in expenditure. Both doctors and patients are expected to manage under grossly inadequate conditions. I hope the leaders of the B.M.A. will investigate and press for action.

As I write the rain is pouring down on us.—I am, etc.,

Bristol Lane.

W. MARSHALL BENNETT.

Wise Action

SIR.—I feel it is time that some of your correspondents stopped moaning and started to get down to make this new Health Service a success. Most of what they write is prejudiced rubbish, to say the least, and I am sure the new scheme can be a success both for patient and doctor, though no doubt changes will be necessary from time to time. I feel that the B.M.A. Council and the Representative Body have acted wisely and, as it may be seen in the years to come, farsightedly.—I am, etc.,

Wolverhampton, Dec. 1, 1947.

D. W. MANNING.

44-hour Week

SIR.—It is high time that somebody thanked those who have tried to maintain the principles on which the British Medical Association is based (see "Points from Letters," May 22, p. 1006 "Self-government") and I take this opportunity of doing so.

The number of our casualties up to the eve of the Special Representative Meeting and reported by Dr. Dain on May 28 were encouragingly small in view of the intensity of Mr. Bevan's attack, and I have no doubt that the figures available by May 26 stimulated Sir William Douglas to write to Dr. Hill on that date (*Supplement* June 5 p. 155). Such a written statement is always useful, and besides, we now know that satisfactory hours of work for doctors will like central clinics, go by the board. However, this can be avoided if the following motion, postponed on May 28 owing to lack of a quorum at 6.30 p.m., is passed by the Annual Representative Meeting at the end of June:

No. 145. Motion by Liverpool.—That the Minister of Health should be told exactly what the doctors can do on the following lines: (a) doctors will work a 44-hour week or as advocated by the T.U.C. for their supporters and will take the holidays with pay customary for Civil Servants of equal status; (b) the State must provide the receptionists and filing-clerks necessary to enable doctors to devote themselves to clinical work; (c) existing semi-private and private beds will be reserved for the use of patients who prefer to see their doctors privately outside State hours. When the Government provides more free beds the percentage of pay-beds can be kept up if the public voluntarily contributes the necessary capital.

Clause (a) now has special significance in view of the following sentence taken from Sir William's letter: "The charging of a private fee to a patient on a doctor's public list for anything within the field of general medical practice would, in the Minister's view, be repugnant to the whole new health scheme." The Representative Body's acceptance of the B.M.A. Council's Recommendation A to co-operate conditionally amounts to handing the Minister a blank cheque. It is likely to cause more friction than did the way in which a majority wish was waived in favour of a minority, as in the case of the April plebiscite result of a 64% vote against accepting service. It will be inconsistent if the representatives who on May 28 set

a precedent for an eight-hour working day—for more than half of them left the meeting before the end—do not on June 29 preach what they practised and vote for Clause (a) of Motion 145, thus giving doctors a chance to think again and providing the Council with the powder and shot they now appear to lack.—I am, etc.,

Liverpool.

H. RICHARD BICKERTON.

The Independence Fund

SIR.—History has again resembled itself, and brilliant leading articles cannot conceal the fact that under B.M.A. leadership medicine and the profession have been betrayed. This time, unfortunately, the results are likely to be very much more considerable than in 1911. An impregnable position has been reduced by sowing doubts and dissension within, and a large number of colleagues have already voted away the constitutional right of British citizens of access to the courts of the country. Perhaps it is hardly surprising that such men are now no more mindful of the more altruistic principles which until recently found so much space in your pages.

We are now left with a "soldiers' battle." One of the first questions which immediately arises in the minds of those of us who backed our support with such money as we could afford is what is now to be the future of the "independence fund" to which we were asked to subscribe. Of the two declared objects of the fund one was to organize the unification of the profession in its expressed determination not to accept service, the other to provide financial aid to practitioners who may suffer hardship as a result of their loyalty to the cause of the profession. As a prompt subscriber I wish to know at once what interpretation is likely to be placed by the trustees on the loyalty of those members of the profession who are unable to share the view expressed by Dr. Dain that the present debacle is in reality a great victory, and who are still not prepared to sign away either the great and abiding professional principles for which we have stood or the few personal rights remaining to us, such as access to the courts, by accepting the terms of service.—I am, etc.,

Carlisle

C. GORDON HARPER.

Defeat or Victory

SIR.—In April the Council instituted a plebiscite in order to find out whether the attitude of the profession towards the N.H.S. Act was such as to warrant an all-out fight against the Minister. The accepted terms were that only if 13,000 general practitioners voted against it would the profession be called to fight. Unfortunately 13,000 general practitioners did not vote against it—much to the disappointment of a large section of the profession, including some members of Council. The fight, therefore, was off. The Council, recognizing that there was nothing else to do, drafted Recommendation A, and submitted it to the profession, to the majority of which it meant nothing else than what it was—a symbol of defeat. Yet on May 28 we find this same symbol of defeat carried bravely aloft on the rostrum of the great hall, as a flag of victory—of a victory, the greatest that has been won against this or any other Government: surely a strangely accommodating recommendation, but only as strange as the sight of the members of Council urging us all to surrender unconditionally.—I am, etc.,

Nantwich, Cheshire

OLIVER H. BLACKLAY.

Medical Trade Union

SIR.—Dr. R. E. Clarke (May 29, p. 1048) has in my opinion hit the nail right on the head when he advocated the formation of a medical trade union. In my presidential address to the Northern Ireland Branch of the B.M.A. in 1935 I said that only the formation of such a union, which would ostracize professionally and socially any and every doctor who refused to join, could save our profession from disaster, and unfortunately in the absence of such a union disaster has overtaken us.

Dr. Clarke advises that the B.M.A. should "transform itself into a properly constituted trade union," but I understand that under its articles of association this is impossible. Should an alteration of these articles which would permit this to be effected be impracticable, could not the B.M.A. foster the formation of such a union to work in close liaison with itself?

I also advocated the fixing of a substantial annual subscription—£10 10s. at least—and the accumulation of a substantial fighting fund. Had this been done even ten years ago we would now have a fund of some millions and would be in a position to fight any Government to a successful finish. Unless such a union is formed the profession of medicine in Great Britain and Northern Ireland will deteriorate to such an extent that no one can be a member of it and retain his independence and self-respect, nor can the standards and traditions which constitute a precious heritage be maintained.—I am, etc.,

Belfast.

W. LYLE.

SIR.—Kindly permit me to express my strong support for Dr. R. E. Clarke's proposal (May 29, p. 1048) that the B.M.A. constitute itself a legal trade union affiliated to the T.U.C.

On July 5 the great majority of doctors will find themselves to be subcontractors to His Majesty's Government under conditions which no trade unionist would tolerate for one week.

As members of a properly constituted trade union our minimum demands should be: (1) A 44-hour week. (2) Payment at time-and-a-half rate for overtime up to 12 hours a day and double time for any longer hours worked. (3) Holiday with pay. (4) Locum provided free in sickness or when on holiday. (5) Transport provided. (6) Compensation for accident or illness sustained while at work. (7) Special payment of "danger money" for work in pathology, bacteriology, and infectious diseases. (8) Provision of staff to do work of secretary, telephonist, and receptionist. (9) Provision of surgery with furniture and all medical instruments, or payment or rent for those now supplied by doctor.

I submit that these demands at no point go beyond well established trade union principles and practices, and that until the B.M.A. is a trade union the practice of medicine will continue to be the last example of sweated labour in Britain.—am, etc.,

Isle of Barra

NORMAN J. L. MACKINVEN.

POINTS FROM LETTERS

Soil Fungi

DR. DUDLEY F. TORRENS (Market Rasen, Lincs) writes: The stupefaction of soil fungi arose out of the successful work of the late Sir Howard in practical agriculture, and the work of Dr. M. C. Rayner. It has found corroboration in field work by agriculturists, in practical health studies by Sir R. McCarrison, and in social surveys great and small in all parts of the world. These have all approached the problem as one of agriculture, as it ought to be, but it has been derided as "cranky," "uneconomic" costly in labour and money etc., and so far has failed to get the backing it deserves. The question arises whether the examination of these fungi might not yield in the laboratory a product which used as a food accessory might make available to humanity the undoubted great increase in resistance to disease and increased bodily and mental vigour which we are denied through faulty agriculture.

Treatment of Pruritus Ani

DR. H. MARGULIES (London, N.W.2) writes: I have read with great interest Dr. Alexander Orley's letter (May 8, p. 904) on pruritus ani and feel that both his explanation of its cause and the suggested therapy merit some comment. . . . The "functional pruritus ani" for which no cause can normally be found (and these mainly a matter of discussion) normally starts with an accidental irritation, followed by scratching, infection, etc.—the recognized vicious circle which usually foils all endeavour to cure it.

The rational therapeutic approach, therefore, will require to combat the two main links in the chain of mentioned factors, and these are (a) irritation, and (b) infection. In the last six months I have used an ointment containing 0.3% of phenylmercuric nitrate in combination with "amethocaine" and benzocaine ("polycrest cream"). Of the 12 cases under my care 10 were cured within 4 months, and some of these patients had a history extending over 3-4 years. . . .

Terms of Service

DR. F. C. MCN. MCLWICK (Callander, Perthshire) writes: . . . Having been advised (or ill advised) to take part in the Health Service and probably having somewhat unwillingly taken the advice it is not time that the terms of service were discussed openly? . . . I have had quite enough of hush hush, now now, come come. Having lost our right to earn a considerable part of our living, is it not time to discuss and insist that the terms of service will be sufficient to recompense us in full? . . .

on leave, she obtained the F.R.C.S.Ed., and in 1941 was appointed superintendent of the Medical School Hospital. The next year she was called to succeed Dame Edith as principal, and quickly her great ability and energy were evident in the raising of standards and the maintenance of the highest traditions of Christian medicine. During the recent communal disturbances Dr. Pollock was put to a very great strain, working incessantly, taking but a few hours of rest by day or night. It was due to her initiative in establishing a cholera hospital that this disease was controlled among the tens of thousands of refugees who were being cared for in the inadequate transit camps. On Easter Sunday night she was last seen visiting a seriously ill patient at 1.30 a.m. She was found dead in her bed next morning from the condition of which she had premonitions, though she refused to modify the course of her life and the burdens she so readily accepted. Thus her death was but the crown of a living sacrifice. As a local official put it, "I often felt ashamed that a woman could do so much." Two days of mourning were observed in the city, and from the theatre sweeper to the wealthiest patient in the district there will be sorrow as long as her memory lives. In Dr. Pollock a very strong personality which had surmounted many difficulties was combined with a unique degree of selfless giving of herself in the service of others. India and the profession will be immeasurably poorer for her loss.

Dr. LEONARD EDGAR WHITAKER, who died on May 12 at the age of 72, was the seventh son and youngest child of Joseph Whitaker, founder of *Whitaker's Almanack*. He was educated at Lansing College and St. Bartholomew's Hospital, qualifying in 1899. He was ophthalmic house-surgeon to Dr. Vernon, whose other junior was Walter Jessop. He was an enthusiastic sportsman, and during his time at the hospital was captain of the association football team and of the combined hospitals team. On leaving Bart's Dr. Whitaker travelled to New Zealand with a fellow student, returning to England on the outbreak of the South African war. He served throughout as a civil surgeon and was awarded the medal and five clasps. Again coming back to England he started in practice at Diss, Norfolk, but in 1910, attracted by his earlier visit to the country, he went with his wife and two small children to New Zealand, settling in Palmerston North. He became ophthalmic surgeon to Palmerston North Hospital, and later its treasurer. He was instrumental in raising funds to extend it and make it at that time the most efficient and up-to-date hospital in New Zealand. Dr. Whitaker also became medical officer of health for the district, although troubled by increasing deafness, and in the great influenza epidemic after the 1914-18 war he gave devoted service. The lessons he learned at this time had much to do with the further improvement and expansion of the local hospital service. In 1920 he left for England and joined the family publishing business of J. Whitaker and Sons, Ltd., becoming a director and later managing director of the firm. He was keenly interested in literature and in the book trade. Although his main interests in later life were literary, he was croquet champion on several occasions, both in England and New Zealand. After croquet his principal diversion was motor-cruising on the Thames. He leaves a widow and two sons.

Dr. DOUGLAS EDWARD WILSON died suddenly from a heart attack at his home in Bishop Auckland, Co. Durham, on May 20, at the age of 45. Dr. Wilson graduated in the University of Aberdeen in 1925, and served in the Colonial Medical Service in Tanganyika Territory from 1928 until 1942. During the last five years of that period he was working as a pathologist. Owing to temporary ill-health Dr. Wilson returned to England, where he held laboratory appointments until 1943, when he joined the R.A.M.C., serving in France and the Middle East. He was finally assistant director of pathology to "Paiforce" with the rank of lieutenant-colonel. On his release from the Army Douglas Wilson rejoined the Colonial Service as senior pathologist, Palestine, and on his retirement from this post he was offered and accepted the appointment of area pathologist in County Durham. Dr. Wilson was an enthusiastic and indefatigable worker, and published several contributions to medical literature. All who knew him will feel that they have lost a charming, sincere, and sympathetic friend, and the high esteem in which he was held, not only by his professional colleagues but also by everyone who came in contact with him, will comfort his widow and two sons, to whom the deepest sympathy is extended.—H. J. L.

Dr. LAURENCE WILLIAM POLE, who died at Edinburgh on May 21, was a student at Edinburgh University. He graduated M.B., Ch.B. in 1901, and took the D.P.H. in 1906. For a time he was engaged in general practice in Edinburgh and then in Canada. Returning home, he took up public health work and was a student M.O.H. for the City of Worcester, and later

county medical officer for Radnorshire. His career was interrupted by the first world war, when he served in France with the R.A.M.C. In 1920 he was appointed medical officer of health for Llanelli Borough and continued in this capacity until 1944. His medical colleagues expressed their appreciation of his work over a period of twenty-four years at a farewell meeting just before he went into retirement. Dr. Pole possessed the traditional characteristics of his race—to the casual acquaintance he might appear distant and reserved, but to anyone privileged to know him his friendship was something of genuine value. He did much for public health but frequently regretted that he could not do more. He was a great lover of children, and never did he appear happier than when he was among them at the annual summer camp on Pendine sands, which had been established by him in 1923. He is survived by his widow and one son, Dr. Alan Chateris Pole.—D. M.

Dr. ALLAN LEONARD SMITH TUKE died suddenly at the age of 82 at his home in Dunfermline on May 25. Dr. Tuke, who was Dunfermline's oldest practitioner, was the youngest son of the late Sir John Batty Tuke. A native of Edinburgh, he graduated M.B., C.M. in 1887, and continued his studies at Leipzig and Vienna. He was Prof. Sheen's house-surgeon at the Edinburgh Royal Infirmary before settling in Dunfermline as assistant to the late Dr. Arthur Drysdale, subsequently becoming his partner. Dr. Tuke was for many years the senior member of the honorary medical staff of the Dunfermline and West Fife Hospital. He was associated with this institution from its inception and was largely responsible for the extensions to the hospital which were completed in 1931. In 1888 Dr. Tuke enlisted as a trooper in the Fife Light Horse, a unit of the Old Volunteers, which later became part of the Fife and Forfar Yeomanry. In 1914 he was mobilized with his regiment, serving with the rank of major in the Egyptian and Palestine campaigns and being awarded the M.C. in 1916. After the war Dr. Tuke was one of the founders of the Dunfermline branch of the British Legion and acted as its chairman for a number of years. In April, 1931, he was made a Free Burgh of Dunfermline in recognition of his public services. Dr. Tuke had attended a meeting of the managers of the Dunfermline and West Fife Hospital on the day before his death and had been seeing patients at his home the same afternoon. He was able to recall a time when operations were conducted on a kitchen table by the light of a tallow candle and with the assistance of a handywoman. In 1938 Dr. Tuke was appointed a Deputy-Lieutenant of the County of Fife. He had been member of the British Medical Association for many years and was president of the Fife branch in 1922. He was one of the original members of the Carnegie Dunfermline Trust and inspired and originated one of its most important enterprises, the setting up of the Dunfermline College of Hygiene and Physical Education.

Dr. CHARLES DAINTY HATRICK, who was for thirty-six years in practice at New Barnet, Middlesex, died on May 31 at the age of 72. Dr. Hatrick had only returned the week previous from South Africa, where he went last year to visit his two daughters. A student at University College Hospital in closing years of the last century, he graduated in 1901 and proceeded M.D. two years later. The teaching staff at U.C. included such brilliant men as Gowers, Barlow, Sidney Mart Victor Horsley, and Godlee, and it was here that Dr. Hatrick began a life-long friendship with Wilfred Trotter. Immediately after qualifying, he went out to the South African war as a civil surgeon. Returning home, he did some house appointments, and then settled in New Barnet, where he remained until his retirement in 1940. Hatrick was a man of outstanding ability, of courage, and of decision. He was a quick worker, a quick thinker, and possessed of abundant energy. Although not of robust physique he carried on an extensive practice without apparent effort. He was a member of the B.M.A. long standing and took a great interest in the Association's work. He was the first chairman of the newly created Barnet Division, president of the Hertfordshire Branch, and an original member of the Hertfordshire Local Medical and Panel Committee, of which he was chairman for four years. In 1935 he went out to South Africa as a representative of the B.M.A. to the South African Medical Association Congress. In all his offices he gave of his best and never spared himself. In the first world war he served with the R.A.M.C. in India, and the last war he played his part as a member of a National Service Military Recruiting Board. His leisure was spent in the garden. He was an expert gardener, and he grew flowers of great beauty that were a source of delight to his friends. He was singularly fortunate in his married life. To his wife and to his three children, a son in the medical profession and two daughters, one also a doctor, married and living in South Africa, the sympathy of all his friends will be extended.—W. G. H.

Medico-Legal

FAILURE OF ANOTHER RESTRICTIVE COVENANT

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

Last year the peace of mind of medico-legal draftsmen was disturbed by the decision of the Court of Appeal in the "Okehampton case." In this case of *Routh v. Jones* the Court of Appeal declared invalid a restrictive covenant in an agreement between a principal and an assistant, with the effect that the ex-assistant was left free to compete in practice with his former employer. The covenant had been drawn in a form quite commonly used. Now the Court has upset another restriction which, although the agreement itself was not a very usual one, was by no means unusual. As in last year's case, the decision doubtless renders useless several covenants on which practitioners are now relying for protection if their present relationship with partners or assistants should end.

Dr. Robert Donaldson Jenkins had a general practice in the Gloucestershire countryside just north of Bristol. The bulk of the work was the treatment of common ailments and injuries; there was the ordinary proportion of midwifery cases and of minor surgery but no specialist work. In 1935 he married a lady who had just qualified; she helped occasionally with the practice but took no regular active part. Early in August, 1939, Dr. Jenkins entered into partnership with Dr. Alexander C. Reid. As the doctor's wife, Mrs. Rosalind Mary Seymour Jenkins, was well known to the patients of the practice as a doctor on her own account, Dr. Reid desired to guard against the possibility that after Dr. Jenkins retired or died, or if she set up in practice on her own in the district patients might consult her for she was in a specially favourable position to acquire a knowledge of the practice. The partnership deed therefore contained a clause providing that during the continuance of the partnership or if Dr. Jenkins died or withdrew from the practice Mrs. Jenkins should not at any time thereafter practise as a physician or surgeon or apothecary within a radius of five miles, or professionally visit or consult with any of the patients of the practice. During the continuance of the partnership however she could see patients of the practice by consent of either partner and account to the partnership for the fee.

At the end of August Dr. Jenkins was called up for service in the Navy, and by arrangement with the partners Mrs. Jenkins worked for the partnership till through the war as an assistant. This engagement ended at the end of March, 1947. Dr. Jenkins had died in September, 1946. Mrs. Jenkins then put up a plate with her name and qualifications and Dr. Reid, who had built another surgery and wished to take in another partner, objected that she was breaking her restrictive covenant. She moved the Court for a declaration that the covenant was invalid, saying that it covered doctors well outside the practice and also many kinds of special practice and even the duties of a works medical officer.

Judgment

The judge, Mr. Justice Rottner, in the Chancery Division of the High Court, heard evidence from a number of the British Medical Association on the precise meaning of the terms "consultant," "specialist," and others used in the evidence. He disregarded the old authorities on the ground that the approach of the courts to covenants of this nature is now fundamentally different from what it had been when they were decided. He bore in mind, while not considering it the decisive factor, that the area of restraint included a built-up area on the outskirts of Bristol from which the partnership did not normally draw patients. He was much impressed by the fact that the restriction was not limited in time. There was no evidence to show why this should have been necessary, and he did not infer that it was in the least necessary to preserve the goodwill. He bore this in mind also when deciding on the question generally. Moreover, the covenant would prevent Mrs. Jenkins from acting as a consultant or specialist in medicine or surgery, although no such work had ever been done by the partnership. The question of

whether the restriction on practice could be severed from that on visiting or consulting with patients of the practice did not arise, because the second restriction was as bad as the first. Consultation was not part of the work of the practice, and the whole sentence was hopelessly vague. He thought that "patients of the practice"—a phrase of very uncertain meaning—meant persons who might at any time during Mrs. Jenkins's lifetime after the termination of the partnership be treated as patients of the practice. Even if counsel's suggestion was right, that the phrase covered only regular patients, Mrs. Jenkins could never know whether a given person was or was not a patient of the partnership. If she set up in practice in London and somebody came from the prohibited area on a visit, she would clearly be guilty of breaking the agreement if she treated him. Restrictive covenants are construed against the persons who invoke them, and he did not feel inclined to guess at some narrow meaning which would save the clause from defeat. He therefore declared that the whole restriction was void and unenforceable as contrary to public policy, too vague, and in unreasonable restraint of trade.

Like all other decisions in cases of this nature this decision turned largely on the facts, and must not be interpreted as being of universal application.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

On May 29 the degree of M.D. was conferred on K. S. MacLean and P. F. Barwood.

UNIVERSITY OF GLASGOW

George McCreath Wyburn, M.B., Ch.B., F.R.F.P.S. (Glas.), Senior Lecturer in the Anatomy Department of the University has been appointed Regius Professor of Anatomy in succession to Prof. William James Hamilton, D.Sc., M.D., F.R.S.E., who has retired.

UNIVERSITY OF LONDON

Philip H. Murchiner, C.B., C.B.E., M.D., M.S., F.R.C.S., has been reappointed a member of Convocation (Medicine) on Senate of the University for the period 1948-52.

John William Stewart Blacklock, M.D., F.R.F.P.S., professor of pathology in the University of Glasgow since 1937 and director of the Institute of Pathology at the Royal Infirmary, Glasgow, has been appointed to the University Chair of Pathology, tenable at St. Bartholomew's Hospital Medical College, from Oct. 1.

James Whillis, M.D., M.S., F.R.C.S., has been appointed to the Chair of Anatomy tenable at Guy's Hospital Medical School, from Oct. 1.

The title of Reader in Morbid Anatomy in the University has been conferred on Daniel Merlin Pryce, M.D., in respect of the post held by him at St. Mary's Hospital Medical School.

UNIVERSITY OF WALES

The following candidates for the degrees of M.B., B.Ch., at the Welsh National School of Medicine have satisfied the examiners at the examination indicated:

Surgery—Sarah A. Chard, G. J. Davies, Joan V. Davis, Janet Dean-Jones, T. Griffiths, E. I. Harzard, Ben H. Jones, Rosina E. Jones, D. M. D. King, G. M. Reynolds, Esme S. Rogers (with distinction), Mary C. Sumpster, G. Thomas, J. D. Thomas, J. A. Wilkinson.

ROYAL COLLEGE OF PHYSICIANS OF LONDON

Dr. J. W. Trevan, F.R.C.P., F.R.S., will deliver the Bertram Louis Abrahams Lecture on "Curare and Curarimimetic Drugs" at the College (Pall Mall East, S.W.) on Tuesday, July 13, at 5 p.m.

The Mitchell Lecture, to be given by Dr. Robert Coope, F.R.C.P., has been postponed till Thursday, Nov. 18.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND

On June 7 Prof. J. A. Ryle delivered a lecture at the Royal College of Physicians of Ireland on "The Modern Concept of Social Medicine." The President, Dr. Bethel Solomons, presided, and a vote of thanks to the lecturer was proposed by Dr. A. Parsons and seconded by Prof. T. G. Moorhead.

The following have been admitted as Fellows of the College: R. S. W. Baker, M. D. Hickey, F. E. Pilkington, C. B. Robinson.

The following have been admitted as Members of the College: J. G. Callanan, S. Davis, L. Godfrey, K. W. Hazratji, P. J. G. Quinn, M. Brown, D. C. Connolly, J. O. Doyle, M. F. Healy, T. Lynch, J. McNutt, J. P. Malone, R. Sahu, R. H. O'Hanlon.

ROYAL COLLEGE OF SURGEONS IN IRELAND

The following officers have been elected for 1948-9: *President*, Prof. H. S. Meade; *Vice-President*, Prof. William Pearson; *Other members of Council have been elected as follows*: J. F. L. Keegan, R. A. Stoney, H. Stokes, E. L. Sheridan, J. F. Devane, A. A. McConnell, T. O. Graham, W. Doolin, W. C. P. Smyly, F. Gill, A. B. Clery, I. Fraser, A. S. Pfrench-O'Carroll, T. G. Wilson, M. P. Burke, R. R. Woods, J. H. Coolican, T. A. Bouchier-Hayes, and N. A. Kinnear.

ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

At the meeting of the Council of the College, held on May 22 with the President, Mr. W. Gilliatt, in the chair, it was announced that Dr. Emil Novak, Baltimore, U.S.A., had accepted an invitation to become an Honorary Fellow of the College. Dr. Novak was appointed lecturer for 1948 under a lectureship founded to cement more closely the bonds of friendship between the British Empire and the United States of America. Prof. N. W. Philpott (Montreal) was appointed William Blair Bell Memorial Lecturer for 1948.

The following were elected to Council to fill vacancies caused by retirement, statutory and otherwise: As representatives of the Fellows: Prof. O'Donel Thornley D. Browne (Dublin), Mr. Malcolm Donaldson (London), Mr. H. L. Hardy Greer (Belfast), Prof. Hilda Nora Lloyd (Birmingham), Mr. Harold Jordan Malkin (Nottingham), Dr. Douglas Miller (Edinburgh), Prof. H. J. Drew Smyth (Bristol). As representatives of the Members: Mr. Donald Blake Fraser (London), Dr. Robert James Wotherspoon (Glasgow).

The following were admitted to the Fellowship of the College: J. O. Baker, S. C. Bose, F. J. Burke, H. H. Caple, W. Clement, G. J. StC. Fisher, I. Goldberg, C. J. K. Hamilton, J. S. Henry, O. S. Heyns, J. Howkins, J. G. H. Ince, Hilda M. Lazarus, D. M. Lindsay, R. Lodge, D. M. Low, J. R. McArthur, K. F. Mackenzie, P. A. McLeon, R. B. Meiklejohn, Jocelyn A. M. Moore, A. B. Nash, I. Y. Patrick, Susanne J. Paterson, H. N. Ray, Helen E. Rodway, W. N. Searle, G. A. Simpson, J. R. Vant, G. M. White, W. R. Winterton.

The following were admitted to the Membership of the College: S. C. Anderson, E. C. Bryant, Margaret E. M. Boulton, J. M. Bowen, J. C. McC. Browne, J. T. Burrowes, R. W. Burslem, A. W. Chester, J. Crawford, L. A. Cruttenden, P. C. Denham, J. C. H. Dunlop, S. Evans, J. B. Fleming, J. F. Foulkes, D. C. Galloway, S. F. Hans, Betty Hargreaves, J. R. Hassard, Rosa Hertz, J. B. Hurll, P. S. Jaikaran, Eileen I. Jamieson, E. W. Jones, M. M. Kriseman, Sylvia Lerer, Una G. Lister, Florence P. Logan, J. T. Louw, S. D. Loxton, A. M. Michael, N. V. Mody, Cecilia M. Murray, G. S. Musgrove, M. J. D. Noble, K. Pasricha, R. G. Patel, A. E. Perera, P. T. Por, R. W. K. Purser, T. F. Redman, O. A. Schmidt, F. Shaw, B. H. Sheares, D. M. Sheppard, W. R. Sloan, B. S. Surti, D. A. Thomson, J. G. Thurston, May D. Westerman.

Feeding customs, like any other, vary with the way society is organized. The three square meals proverbially advocated by our forefathers as necessary for a good day's work are unsuited to people working in offices or factories, who prefer more and smaller meals. Many believe that their minds do not work so keenly when their stomachs are full, and present difficulties in preparing substantial meals confirm their choice. A Research Group appointed by the London Council of Social Service Standing Committee on Communal Feeding and the London and Middlesex Standing Conference of Voluntary Youth Organizations has recently investigated the meals taken by juvenile workers in the London area. The Group interviewed first 36 boys and 18 girls, most of whom were aged between 15 and 18, and then a further 112 boys and 84 girls. It found that six meals a day were almost universally accepted, and a seventh was often taken by those who frequented clubs.

Breakfast on weekdays is light and sometimes hurried, though over half have something cooked. Nearly all take sandwiches or cake to eat at work at 10 a.m., and some also drink tea or cocoa. They have a mid-day lunch at a canteen or restaurant or at home, and most then have a snack in the middle of the afternoon. All have tea on returning home, which may be a cooked meal if the lunch was small, and most of them have supper between 9 and 10.30. The likes and dislikes of these young people for different kinds of food vary considerably. Fish is the least popular animal food: indeed, many eat little or none. But the Group comments that "fish and chips" may have been regarded in the inquiry as an item distinct from mere fish. Turnips and parsnips are unpopular, and 10 of the group of 56 dislike one or all green vegetables except beans. The Group concludes that boredom conduces to hunger, which is readily satisfied by snacks, and since many make a poor breakfast employers might provide light refreshments at the start of the day to encourage work. The short breaks for rest are better times than the mid-day meal for introducing any supplementary foods, such as milk, that may be necessary. On the whole, however, the meals of 50% or more of these juveniles are satisfactory.

Medical Notes in Parliament

NATIONAL HEALTH SERVICE

There were presented to Parliament on June 2 Draft Regulations entitled: the National Health Service (Superannuation) (Amendment) Regulations, 1948; National Health Service (Superannuation) (England and Scotland) Regulations, 1948; National Health Service (Transfer of Officers and Compensation) Regulations, 1948; and the National Health Service (Executive Councils) Amendment Regulations, 1948. On June 3 there was presented the National Insurance (Medical Certification) Regulations, 1948.

On June 9 there were presented to Parliament the National Health Service (Scotland) Superannuation (Amendment) Regulations, 1948, and the National Health Service (Transfer of Officers and Compensation) (Scotland) Regulations, 1948.

Interim Contracts for Specialists

Sir ERNEST GRAHAM-LITTLE on June 8 invited Mr. Bevan to publish the interim terms of remuneration for specialists. He said these had been made known to Regional Boards, but not to those who were to be asked to serve under the Health Act as specialists.

Mr. BEVAN replied that whole-time specialists who, by virtue of Section 68 of the National Health Service Act, 1946, were transferred on July 5 to the employment of a Regional Hospital Board or a Board of Governors of a teaching hospital would continue, for the time being, to receive the same remuneration as they did before the appointed day. Part-time specialists who, in general, were not so transferable and whose appointments would therefore lapse on July 5, would be offered temporary contracts remunerated at the flat rate of £200 per annum for each half-day per week up to a maximum of £1,600. These terms of remuneration were broadly based on current practice where part-time visiting staff were paid for their hospital appointments. They were designed simply as interim payments on account until the recommendations of the Special Committee had been discussed with the profession, and a new scheme of remuneration worked out. As soon as that was done adjustments would be made so as to apply the new scheme as from July 5 (even if the discussions were prolonged beyond that date) and to do so in such a way as to bring the specialist's remuneration up to a level appropriate to his seniority and experience.

Sale of Goodwill

On June 10 Sir ERNEST GRAHAM-LITTLE asked Mr. Bevan whether, in view of the fact that general practitioners could carry on private practice in conjunction with public practice under the National Health Service Act, 1946, he would introduce amending legislation to enable them to dispose of the goodwill of their private patients.

Mr. BEVAN replied that he could not do this, but he pointed out that full compensation was provided to cover both element in these combined practices.

Medical Certificates

Mr. STEELE stated on June 7 that under the National Health Service certificates signed by any qualified medical practitioner would be accepted in support of a claim for sickness benefit. It was not essential that the certificates should be on the standard official form, but convenient that they should be. Medical practitioners practising outside the National Health Service could obtain these forms by applying to the Executive Council set up under the Act.

RADIOACTIVE SUBSTANCES BILL

The Radioactive Substances Bill, which had already passed the House of Lords, was considered in Committee by the House of Commons on June 4. On Clause 3 Major VERNON moved to omit the provision authorizing the sale by registered pharmacists and sellers of poisons of substances containing more than a prescribed quantity of radioactive element. He said that special skill and elaborate precautions needed to avoid the dangers in handling these substances were outside the range of education of the ordinary pharmacist and outside the range of many medical practitioners. It had never been the practice to sell radium and radon in small quantities all over the country. They had been prepared in establishments equipped for the purpose and taken direct to the hospitals where they were used. Even so there had been accidents and losses.

Mr. Linstead said that beside the substances mentioned by Major Vernon there was a group of preparations in which very minute quantities of radioactive substances were intro-

*The Liniment with a
constitutional action*

ANALJOL

A methyl aspirin preparation for external use in rheumatism and neuritis. It is non-staining and non-greasy and has an agreeable odour.

A double action, analgesic and counter-stimulant, supported by the effects of aspirin esters operating locally and constitutionally, ensures substantial relief from pain arising from the common fibrositic disorders of muscles, ligaments, nerves and joints.

Formula :—

Methyl Aspirin 12%	Phenyl Aspirin 2%
Camphor 12%	Menthol 8.75%
	Ol. Thymi Rub. 8%
Alcoholic Solution of Terpeneol 57.25%

'PALUDRINE'

TRADE MARK

The New Antimalarial

Extensive clinical investigations have established that 'Paludrine' is a highly efficient antimalarial with important advantages over mepacrine and quinine.

- 'Paludrine' controls the clinical symptoms of all forms of malaria and terminates the attack.
- 'Paludrine' is a true causal prophylactic in malignant tertian malaria and a partial causal prophylactic in benign tertian malaria.
- It produces radical cures in malignant tertian malaria and controls relapses in benign tertian malaria indefinitely on a twice-weekly dosage.
- 'Paludrine' is a colourless drug and in normal dosage does not produce unpleasant symptoms of any kind.

'Paludrine' tablets of 0.1 gramme strength are issued in packings of 30, 100 and 1,000.

duced. Radioactive mud and waters were used in medicine. He hoped the Minister would bring under control substances with very small quantities of radioactive material which at present were sold without control and could easily be used to exploit credulous people. The coming of the National Health Service probably meant that there might be preparations, in addition to those now known, which could properly be prescribed by the general practitioner for use by a patient under his direction and which would not require elaborate machinery.

Capt. FIELD said that if the nomination of properly qualified people were left to the Advisory Committee it should not be rigidly confined to medical practitioners, dental practitioners, registered pharmacists, or authorized sellers of poisons. One or two hospitals in London had on their staffs physicists who were not necessarily medical practitioners, yet would be ideal persons to handle and prescribe these substances in certain cases.

Mr. BEVAN said this point should be raised on another part of the Bill. The subsection to which Major Vernon's amendment was directed dealt with persons who sold or otherwise supplied these substances and not with persons who used them. All kinds of radioactive substances such as ointments and hair restorers, might contain dangerous percentages of radioactive matter and it was essential that they should not be allowed to be sold freely.

Major Vernon's amendment was negatived. He then moved the deletion of the "escape Clause" providing a period of three months from the appointed day during which any qualified practitioner who had applied for a licence could act as though that licence had been granted.

Mr. SOMERVILLE HAS also hoped the Committee would not agree to the removal of this Clause. Only a few doctors specialized in this line of treatment and they did not undertake it lightly. There must be a Clause of this sort so that treatment already begun could continue in the interval between application for licence and the granting of it.

Mr. BEVAN said he did not know how long would be required to grant the licences. It might be a month or more, but it would be. The Government could not say that in the appointed day all work must stop. The amendment was withdrawn and Clauses 3, 4, and 5 were agreed to the Bill.

Advisory Committee

On Clause 6 Comm. under Sub-section 1, Mr. BEVAN said that the Steel Institute and the Institute of Metals, being asked to send have representation on the Advisory Committee.

Mr. HASTINGS asked whether the Minister of Health would suggest to the College of Physicians and the Society of Apothecaries to the Committee.

Mr. LINSTED felt consulted. It had a representative on the Advisory Committee under the Therapeutic Substances Act.

Mr. BEVAN said that the Committee had been asked by the bodies nominating it to include representatives of the claims of dermatologists. The Committee had accepted the recommendations were made by the Royal College of Physicians. He would investigate to see whether there was any other body of specialists was essential. He would also consider whether there would be directly involved in the matter considered in this part of the Bill, as well as the other bodies.

On Clause 9 Mr. BEVAN said that the Minister had asked himself injured by the Bill, the Minister had asked himself, the inquiry would be made by the Minister.

Mr. BEVAN said that he would be asked to make an inquiry in each case. The Minister would be asked to make an inquiry before the House. The Committee would be asked to make an inquiry through the report stage without further discussion. The Bill was read a third time.

VETERINARY SURGEONS' BILL

Mr. TOM WILLIAMS on June 4 moved the Second Reading of the Veterinary Surgeons' Bill. The Bill had passed the House of Lords. He said the Bill was adding the country's herds of bovine tuberculosis was moved in the supply of veterinary surgeons. Both Cambridge and Bristol Universities were planning courses in veterinary science. Under the Bill the Privy Council could give an appropriate degree of the university would carry with it a registrable qualification as veterinary surgeon. The Bill did not limit the number of universities which would be brought in. The Bill proposed to register and control practitioners who fulfilled its conditions, to place them under the disciplinary control of the Royal College, and to allow them to describe themselves as

"veterinary practitioners." The title "veterinary surgeon" was reserved for the fully qualified person.

Mrs. MASSING said that this country had only 94 veterinary surgeons per million cattle, against 148 veterinary surgeons per million cattle in Denmark and 247 in Switzerland. The suggestion that the intake of veterinary surgeons should only be increased to 220 a year was pitiful.

Mr. KENYON said that sterility in dairy cattle affected one-fifth of the herds. The remainder, after taking three years to come into production, produced only three lactations. If the veterinary profession found a remedy it would greatly contribute to the welfare of the country.

Mr. GEORGE BROWN, replying for the Government, said the figure of 220 qualified entrants annually into the profession had been based on the estimate of the number for whom decent posts could be found, here or in the Colonial Service. The number of unqualified persons admitted to the supplementary register was unlikely to be more than 500 as against 4,000 qualified people on the other register. "Veterinary practitioners" would be allowed to move between tests, to issue certificates, and to act for insurance companies.

The Bill was read a second time.

Purchase Tax on Drugs

The Schedules of the Finance Bill, 1948, were considered in Committee by the House of Commons on June 8. On Part II of the Schedule Mr. N. MACPHERSON introduced the distinction made in levying purchase tax, between drugs mentioned in the *Pharmacopoeia or National Formulary* and unlicensed drugs. He said the Government had made it well understood that the distinction was made in order to protect the public from getting more easily. Sir STAFFORD CROMBIE pointed out that in the matter before the Report stage and the Committee stage of words could be found to distinguish between undesirable and desirable drugs. The Schedules were approved and the Committee Stage concluded.

Employment of Blind Persons.—Mr. GEORGE ISAACS announced on June 1 that the Ministry of Labour had set up a working party to investigate the facilities existing for the employment of blind persons in industry and in public service, and to make recommendations for their development.

Testimony of Enure.—Mr. BRAMWELL on June 1 asked about the treatment of a soldier who suffered from enuresis and was compelled to sleep in the gutter. Mr. MICHAEL STEWART said that the soldier in the gutter was in medical recommendation for his treatment. The arrangements made were calculated to be considerably to his comfort.

Unemployment.—Mr. BEVAN said that the artificial limb supply was now working for the Ministry of Pensions can supply the artificial limbs without undue delay. The artificial limbs required for the National Health Service with the aid of other establishments.

Medical Research Council.—Persons who will be eligible for grant of the disability of partial deafness to qualify for the "disabled" hearing-aid are estimated by experienced otologists to number about 150,000. This estimate is based on a survey by the Medical Research Council.

Approved Societies.—All Approved Societies will be wound up by July 5, 1948. Regulations governing the procedure will be issued shortly.

Anaesthesia in Domiciliary Midwifery.—Asked what progress had been made in providing analgesic apparatus in hospitals and for use by midwives Mr. BEVAN replied that the apparatus was now equipment in hospitals, and 2,820 sets had been supplied for domiciliary midwives who used them for 43,683 cases in 1947 as against 20,507 in 1946. Reports remained favourable. Whether a hospital patient should be given analgesia must continue, he said, to be decided by the doctor in charge.

The Services

Brigadier A. A. Eagger, C.B.E., T.D., and Colonel F. Whalley, C.B.E., D.S.O., T.D., K.H.P., R.A.M.C., T.A., have been appointed Honorary Colonels to the 16th (Airborne) Division, R.A.M.C., and the 49th (W.R. and M.) Armoured Division, R.A.M.C., respectively. The Efficiency Decoration has been conferred upon the following officers of the Territorial Army: Colonels H. J. A. Longmore, W. McK. H. McCullagh, D.S.O., M.C., Major (Temporary Lieutenant-Colonel) J. B. Bishop, Majors (Honorary Lieutenant-Colonel) D. J. Campbell and J. D. Finlayson, M.B.E., and Major J. E. McCartney, R.A.M.C.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended May 29.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales, London (administrative county), will no longer be published.

‡ The 13 principal towns for England and Wales, London (administrative county), and Northern Ireland.

§ The 16 principal towns in Scotland and poliomyelitis and poli-encephalitis for England and Wales, London (administrative county), are combined.

|| The puerperal fever for England and Wales and Eire.

EPIDEMIOLOGICAL NOTES

Infant Mortality

The infant mortality rate, which has been steadily declining since the beginning of this century, reached the record low level of 41 per 1,000 live births in 1947. This low value has received considerable publicity and has been attributed to the current standards of nutrition of mother and infant. It may be of general interest therefore to review briefly the trend of infant mortality from the beginning of this century. What the exact course of infant mortality would have been if there had been no war is a matter for speculation, but the break in the downward trend in 1940 can probably be justly attributed to the outbreak of hostilities. The rate increased then from 51 in 1939 to 57 in 1940 and to 60 in 1941; after 1941 the decline in the infant mortality rate was resumed. To obtain an estimation of the possible trend a curve was fitted to the values from 1900 to 1939 and the extrapolated values found for 1940-7.

Infant mortality in England and Wales, 1900-47.

In the graph which is here reproduced the smooth calculated values are shown as a full line and the extrapolated values as a dotted line. The graph begins in 1900, when the infant mortality rate was 154 per 1,000 live births. Assuming that the average rate of decrease during 1900-39 continued to operate during 1940-7 the calculated infant mortality rate for 1947 is found to be 41, the same as the observed rate. The calculated values for 1940-6, however, were all less than the observed rates.

There is no reason to suppose, from the shape of the curve of infant mortality, that any exceptional depression of mortality in infancy has occurred in the last year or two. It appears that the factors responsible for the decline in the period before 1939 continued to operate. Of these many and complex factors the most important probably is the increase in knowledge of infant welfare and management. The diffusion of knowledge throughout a community is a gradual process and some time elapses before any new idea is universally practised, so that it may be several years before the full effects of this improved knowledge are shown in the infant mortality rate.

Discussion of Table

In England and Wales there was an increased incidence of measles 1,791 and whooping-cough 405, and a decrease in the notifications of scarlet fever 138 and of diphtheria 17.

Very little change occurred in the trend of measles in most areas, and the large increase in notifications was contributed by only a few counties; the largest rises were Lancashire 286, Warwickshire 239, Durham 234, Essex 213, Cheshire 147, London 140, and Nottinghamshire 98.

The notifications of during the week included 3,207, diphtheria 166, cerebrospinal fever 42 paratyphoid 2, and typh

COMING EVENTS

The Annual Meeting of the Royal Society of Medical Illustration will be held at the West Hotel, London W. from Monday, June 21, to Wednesday, June 23, 1937. The hours are 10 a.m. to 4 p.m. on Mondays, Tuesdays, and Wednesdays, and 10 a.m. to 12 p.m. on Saturdays. The exhibition will be opened by the President of the Society, Sir Maurice Cassidy, on June 21 at 11 a.m. All those interested in the subject will be welcome.

Faculty of Homoeopathy
The annual assembly of the Faculty of Homoeopathy will be held at the London Homoeopathic Hospital, Great Ormond Street, London, W.C., on Wednesday, June 23, at 5 p.m., when there will be a general discussion of the National Health Service Act as it affects homoeopathic practice.

S.E. Metropolitan Regional Specialists Association
The first annual general meeting of this association will take place at B.M.A. House, Tavistock Square, at 5.0 p.m. on June 25. The B.M.A. has asked the council of this association to consider acting on its behalf in the area of the S.E. Metropolitan Regional Hospital Board, and this proposal will be discussed at the meeting. A cordial invitation is extended to all members of the specialist and consultant staffs of hospitals, including tuberculosis dispensaries.

National Association of Insurance Committees

The final meeting of the National Association of Insurance Committees will be held in the Spanish Hall, Winter Gardens, Blackpool, on Thursday, June 24, at 10.30 a.m.

Institute of Laryngology and Otology

Dr. Arthur Proetz, of St. Louis, U.S.A., will deliver a lecture on "Medical and Surgical Treatment in Relation to the Physiology of the Nose" at the Institute of Laryngology and Otology, 330-2, Gray's Inn Road, London, W.C., on Monday, June 28, at 5.30 p.m. Questions and a discussion will follow. Admission is by invitation, which may be obtained from the secretary of the institute.

Conference on Maternity and Child Welfare

The annual conference on Maternity and Child Welfare, arranged by the National Association of Maternity and Child Welfare Centres and for the Prevention of Infant Mortality will be held at Friends House, Euston Road, London, N.W., on Wednesday, Thursday, and Friday, June 23, 24, and 25, under the presidency of the Rt. Hon. Aneurin Bevan, P.C., M.P. (Minister of Health). The conference will be opened at 10.15 a.m. on June 23 by Dr. Jane H. Turnbull, chairman of the Association, and Mr. John Edwards, M.P., Parliamentary Secretary to the Ministry of Health. At 11 a.m. Mr. S. F. Wilkinson (Ministry of Health) and Dr. J. A. Scott (London County Council) will speak on "The National Health Service Act as it Affects Young Children," and a discussion will follow. On June 24, at 10.15 a.m., Dr. J. L. Burn (medical officer of health and school medical officer for Salford) and Miss Mary Smith (Manchester) will open a discussion on "Home, School, and Other Environmental Factors." On June 25, at 10.15 a.m., Mr. John Ross (Assistant Under-Secretary of State in charge of Children's Department, Home Office) and a Children's Officer will speak on "The Children Bill," and a discussion will follow. At 2.15 p.m. the Minister of Health will deliver his presidential address. The conference is open to all who are interested in maternity and child welfare, whether representatives of local authorities or voluntary organizations, or as individuals. Tickets for the three days are £1 1s.; for one day or one session, 10s. 6d. A remittance should accompany all applications and should be sent to Miss M. R. Lovelock, secretary of the Association, 5, Tavistock Place, London, W.C.1.

University of Durham: Department of Surgery

Mr. R. Guy Pulvertaft will deliver a lecture in the Royal Victoria Infirmary, Newcastle-upon-Tyne, on Friday, June 25, at 5 p.m., on "Tendon Surgery in the Hand."

Genetics of Cancer

A symposium on the genetics of cancer, organized by the Genetical Society of Great Britain (Lister Institute, Chelsea Bridge Road, London, S.W.1) and the British Empire Cancer Campaign (11, Grosvenor Crescent, London, S.W.1) will be held in London on June 24 and 25. The programme is as follows: June 24, 10 a.m., at Royal Society of Medicine, 1, Wimpole Street, W., "Inheritance of Cancer in Animals"; June 24, 2.30 p.m., at Medical Society of London, 11, Chandos Street, W., "Virus and Carcinogen Induced Mutations." June 25, 10 a.m., at Royal Society of Medicine, "Virus and Carcinogen Induced Mutations" (continued) and "Inheritance of Cancer in Animals" (continued); June 25, 2.30 p.m., at Royal Society of Medicine, "Inheritance of Cancer in Man." A number of American, European, and British scientists will read papers. The meetings are open to all interested in the subject. An informal dinner will be held on Thursday, June 24, at 7 for 7.30 p.m., at Brown's Hotel, Albemarle Street, London, W. Morning dress will be worn. Accommodation is limited to 70.

Tuberculosis Association Annual Conference

The annual conference of the Tuberculosis Association will be held at Queen's University, Belfast, on Wednesday, Thursday, Friday, and Saturday, June 30, July 1, 2, and 3. The programme is as follows: June 30, 2.30 p.m., Dr. Brice R. Clarke (Belfast), "The Northern Ireland Tuberculosis Service"; Prof. Arvid Wallgren (Stockholm), "The Time Table of Tuberculosis"; Dr. Dorothy S. Price (Dublin), "B.C.G. Vaccination of Infants." 8.30 p.m., annual general meeting; Dr. Robert Marshall (Belfast), "There Were Giants on the Earth in Those Days." July 1, 9.30 a.m., Prof. Jorgen Lehmann (Gothenburg), "P.A.S. in Pulmonary Tuberculosis"; Dr. T. G. Dempsey (London), "P.A.S. in Tuberculous Empyema." Dr. A. F. Foster Carter (Frimley Sanatorium), "The Segments of the Lungs"; Dr. Dillwyn M. E. Thomas (Sully Hospital), "The Treatment of Pulmonary Tuberculosis in Relation to the Segments of the Lungs." 2.30 p.m., Mr. J. H. Carver (London), "Silent Renal Tuberculosis"; Dr. Johann Gravesen (Copenhagen), "Combination of Reduced Apical Thoracoplasty and Extrapleural Pneumotomy of the Thorax." 8.30 p.m., reception and entertainment arranged by the Lord Mayor of Belfast. July 2, 9.30 a.m., Dr. Joseph Smart (London) and Mr. W. P. Cleland

(Epsom), "Primary Thoracoplasty"; Dr. James A. D. Deeny (Dublin), "The Epidemiology of Tuberculosis." 2.30 p.m., Dr. Johannes Holm (Copenhagen), "Refined Methods of Search for Tubercle Bacilli"; Dr. J. E. Wolf (Davos), "Some Observations on the use of Streptomycin in Tuberculosis." 7.30 p.m., annual dinner at Grand Central Hotel. July 3, Excursion and golf competition for the Fowler Cup. Information concerning accommodation in Belfast during the period of the meeting may be obtained from Dr. J. E. Geddes, 151, Great Charles Street, Birmingham, 3.

Training as Health Visitor Tutors

A special whole-time course of training for health visitor tutors will be started towards the end of September for a limited number of students. The course will cover a period of not less than three terms in one academic year and be followed by an examination and the award of diplomas to successful candidates. Health visitors with a minimum of three years' experience in health visiting are eligible for this course. Successful applicants will receive an allowance of £150 towards the cost of maintenance, together with the payment of their training and examination fees and the cost of textbooks. They will be required to sign an undertaking that if they pass the examination they will serve as health visitor tutors for at least two years. Application should be made immediately and in any event not later than July 2, to the Secretary, the Ministry of Health, Division 3c, Whitehall, S.W.1.

SOCIETIES AND LECTURES**Tuesday**

EDINBURGH POSTGRADUATE BOARD FOR MEDICINE.—At Edinburgh Royal Infirmary, June 22, 5 p.m. "Clinical Problems of Polymyositis," by Prof. R. E. Tunbridge.

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—June 22, 5 p.m. "Toxic Eruptions, including the Erythema," by Dr. J. E. M. Wigley.

Thursday

MEDICO-LEGAL SOCIETY.—At 26, Portland Place, London, W., June 2, 8 p.m. Annual general meeting. Paper: "Rex v. Camb," by Geoffrey Dorling Roberts, K.C.

Friday

KENT AND CANTERBURY HOSPITAL, Canterbury.—June 25, 5 p.m. Monthly Clinical Meeting.

Saturday

ROYAL SANITARY INSTITUTE.—At Greensfield Health Centre, Mulgrave Terrace, Gateshead, June 26, 10 a.m. Gateshead sessional meeting "The Stigma—A Problem of Social Medicine," by Drs. Jam Grant and C. B. Bamford.

APPOINTMENTS

Arthur Espie Porritt, C.B.E., M.Ch., F.R.C.S., and Henry Osmer Clarke, C.B.E., F.R.C.S., have been appointed to the Civil Consultant Staff of King Edward VII Convalescent Home for Officers, Osborne, Isle of Wight, in succession to Sir Claude Howard Stanl Frankau, C.B.E., D.S.O., M.S., F.R.C.S., and Walter Rowl Bristow, F.R.C.S., deceased, respectively.

Dr. Kathleen B. Cobb has been awarded a Fellowship in Paediatric Psychiatry at the Colorado Psychopathic Hospital (University of Colorado), Denver, Colorado, U.S.A., for the year beginning July 1, 1948.

The Council of the Senate of the University of Cambridge has appointed Richard Edward Montagu Pilcher, M.B., B.Ch. F.R.C.S.Ed., to be Governor of the Boston Grammar School until May 7, 1951.

Mr. Pilcher was educated at the University of Cambridge and at St. Thomas Hospital. He is Honorary Surgeon to Boston Hospital and to Spalding Hospital Consulting Surgeon to the Holland County Council's Maternity and Public Assistance Department; Consulting Obstetrician to the Lindsey County Council's Maternity and Emergency Hospital; and Orthopaedic Surgeon to the Holland County Council and to the Borough of Boston.

J. W. D. Bull, M.D., M.R.C.P., D.M.R., Honorary Assistant Radiologist, National Hospital, Queen Square, London, W.C.

After graduating with second-class honours in the Natural Sciences Tripos at Cambridge in 1932, Dr. Bull qualified by L.M.S.S.A. in 1934, took his M.B. 1936 and the M.R.C.P. in 1937. He took the D.M.R. of London University in 1938 and in the same year was appointed to a Rockefeller Travelling Fellowship. In 1947 he proceeded M.D. Dr. Bull has written on radiological diagnosis of chronic subdural haematoma and the diagnosis and treatment of intracranial tumours.

Zina E. Moncrieff, M.B., Ch.B., M.R.C.P., D.C.H., Honorary Assistant Physician to Children's Department, Royal Free Hospital, Gray's Inn Road, London, W.C.

Dr. Moncrieff qualified at Aberdeen in 1938, took the Diploma of Child Health in 1942, and the M.R.C.P. in 1944. She has written on the diagnosis and treatment of thyroid dysfunction in children.

Dr. James Charles Sleigh has been appointed Divisional Medical Officer for the St. Albans Division (comprising St. Albans City, Harpenden Urban, St. Albans Rural, and Elstree Rural Districts) under the Herts County Council's Health Service scheme and Medical Officer of Health for St. Albans City, St. Albans Rural, and Harpenden Urban Councils.

Ch B at the University of Aberdeen in 1918 and is at present Medical Officer of Health and School. He has long been interested in aviation, holding is an examiner for the Royal Aero Club. "A" he served in the R A M C in Germany with the

DRUMMOND, J. S., M.B., Ch B D P H. Medical Officer of Health, Mansfield
EEDY, B. N., M.B., B.Ch., D P H. Joint Medical Officer, Warsop and Mansfield
Woodhouse Urban Districts and Assistant to County Medical Officer of
Nottinghamshire.

HART, E. W., M.B.E., M.D. M.R.C.P., Honorary Paediatrician, Hampstead General and North-west London Hospital, Haverstock Hill, N.W.

LANCASTERSHIRE COUNTY COUNCIL—The following have been appointed Divisional Medical Officers under the NHS for the districts indicated in parentheses: G. H. Potter, M.B., Ch.B. (D.P.H.) (Aberham, Ashton-in-Makerfield, Aspull, Billinge and Winstanley, Hindle, Runcorn); A. C. Crawford, M.B., Ch.B. (D.P.H.) (Barnoldswick, Bolton-le-Willows, Euxine, Farnworth, Haslingden, Horwath, Littleborough, Oldham, Radcliffe, Salford, St. Helens, Wigan); J. Hallwood, M.D. (D.P.H.) (Blackburn, Burnley, Chorley, Clitheroe, Colne, Great Harwood, Haslingden, Heysham, Preston, South Ribblesdale, West Lancashire, Wharfedale); J. Hallwood, M.D. (D.P.H.) (Crosby, Formby, Littlehampton, Ormskirk, Skelmersdale, and West Lancashire); G. G. Wray, M.D. (D.P.H.) (Chorley, Farnworth, Littlehampton, Ormskirk, Skelmersdale, and West Lancashire).

RUNWELL HOSPITAL, near W. & Essex - Asst. Obst. Physician W. A. L. Haynes, M.R.C.S., L.R.C.P. S. Cohen, M.R.C.S., L.R.C.P.

SEMPLE, A. B., M.D., D.P.H. District Medical Officer of Health Liverpool
ST. ANDREW'S HOSPITAL, B. & L. E.—Consultant Ophthalmologist
M.B., B.Ch. House-physician J. H. F. Wood, M.B., B.Ch. and J. Zamler
M.R.C.S., L.R.C.P.

ST. THOMAS'S HOSPITAL, London SE — Honorary Surgeon, R. H. Bagnall
M.S., F.R.C.S. Honorary Surgeon, Out-patient, C. G. R. F.R.C.S.
Honorary Physician to Deputies, Out-patient, M. J. W. W. Sergeant
M.R.C.P., D.P.M. Honorary Out-patient, H. J. Anders, M.R.C.P.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Hypnosis in Labour

Q.—What are the facts and arguments for and against hypnosis for procuring analgesia in childbirth?

A.—According to J. B. DeLee in *The 1939 Year Book of Obstetrics and Gynaecology* (p. 164) sundry trials of hypnotism during labour have been made since the method was introduced into surgery in 1821. A recent report on 12 cases (with only one failure) is by W. S. Kröger and S. T. DeLee (*Amer. J. Obstet. Gynec.*, 1943, 46, 655). These authors also review some of the earlier literature on the subject. The method has two main features:—(1) hypnosis and (2) post-hypnotic suggestion—i.e. when the patient is in a trance it is suggested to her that labour will be painless. Repeated sittings are given, beginning about the seventh month of pregnancy. During labour itself the patient is hypnotized early in the first stage. Many advantages are claimed: no interference with uterine function; smooth and rapid progress of labour with the patient calm and relaxed; a decreased tendency to haemorrhage and shock; relief of pain; and good anaesthesia. Indeed hypnosis is said to be the only analgesic which is completely safe for both mother and child. Under its influence the patient is able to obey the instructions of the attendant and "bear down" or "relax" accordingly. They can also take nourishment and empty the bowel and bladder at will. Forceps delivery, episiotomy, and perineal repair can all be carried out without the aid of any other analgesic agent.

The disadvantages of the method include the practical difficulties inherent in devoting a very considerable amount of time and care to each individual patient. The same operator has to carry out the hypnosis on each occasion and to attend to others. However, he or she need not remain in personal contact with the patient throughout the whole course of labour. Once the patient is hypnotized, rapport can be transferred to a nurse whose instructions will then be followed by the patient. Perhaps the chief disadvantage of the method is that its success depends on having a confident and experienced operator working with a susceptible patient. Many women are not amenable to hypnosis, it seems likely that hypnosis in labour has a wider application than has been appreciated and the practical difficulties may have been so overstated that it has not received a thorough trial. There is no doubt that it works well in some cases. In certain ways it can be regarded as an extension of "suggestion" therapy which every good obstetrician practices consciously or subconsciously, as part of antenatal care.

Vagotomy

Q.—Is the operation of vagotomy for gastric or duodenal ulcer widely performed? In what type of case is it indicated or contraindicated? What is the prognosis and what are the results?

A.—Vagotomy has been widely practised in America for at least five years, and its use here has been and still is steadily increasing, especially in the last year or so. Indications in this country have been confined almost entirely to two groups of cases. (1) selected duodenal ulcers, and (2) gastro-jejunal ulcers following either short-circuiting operations or gastrectomy. In group 1 the ulcers which respond best are those occurring in young men whose ulcers have failed to respond to extensive medical treatment, where obstructive symptoms are absent or minimal, and where a psychosomatic factor is in evidence. In group 2 vagotomy is probably the treatment of choice, but the possibility that stenosis may follow the ulcer's healing must be borne in mind. Vagotomy is not advocated for gastric ulcer, as it leaves the question of possible malignancy unsolved. This obviously applies in greater degree to the older age groups. The immediate prognosis (provided the nerve section is adequate) is excellent. Follow-up studies are as yet too brief

to merit an opinion on long-term results, but interim results (up to five years) show 75-80% completely satisfactory results and another 10-15% greatly improved.

Acne Vulgaris

Q.—What is the modern theory of the aetiology of acne vulgaris? What success has there been with oestrogens, and what is the rationale of treatment with these hormones and their limits and dangers? The case I have in mind is that of a man of 28 who has suffered from acne vulgaris for 14 years, chiefly about the chin and forehead. His general health is good except for a mild chronic bronchitis and post-pharyngeal catarrh. He has had sulphur lotions, x rays, ung. quinolor, dieting, vitamin A, internal mercury, and ultra-violet rays. Nothing has been of any use except the x rays, which cleared the condition up for eight months, leaving a small area of alopecia on the chin. A second dose of x rays twelve months later had exactly the same effect. Focal sepsis has been removed and a diet poor in fats recommended.

A.—Acne vulgaris is a normal accompaniment of puberty related to the influence of endocrine development upon the activity of sebaceous glands. Similar changes are sometimes seen in infants, possibly consequent upon hormonal influences from the mother. A related affection may accompany disease of the central nervous system, probably the hypothalamus, as is seen in post-encephalitic Parkinsonism. There is often a strong hereditary and familial factor, which in some cases amounts to a gross navoid abnormality (acne conglobata) and is not responsive to any treatment other than surgical. In the ordinary case of pubertal acne there may be a wide range of aggravating factors—psychological, dietetic, focal, sepsis—which may demand chief attention in treatment. Local treatment, including the use of modern degreasing agents, is always important, but each case is an individual problem.

The case described suggests the possibility of rosacea rather than acne, or perhaps the combination. The chronic bronchitis and catarrh suggest, on the one hand, sepsis about accessory sinuses, which would provoke acne or rosacea. On the other hand, it may relate to a catarrhal diathesis likely to be helped by a diet rich in proteins and vitamin B, and restricted in carbohydrates, fluids, and salt. Oestrogens should not be employed in the female unless there is an indication in menstrual irregularities. In the male they are harmless and worth trying in moderate dosage for a period, but results are not very encouraging. There is no doubt of the effect of a large dosage in many cases of acne, but such dosage cannot be regarded as safe or wise. A small dose of stilboestrol will often help in rosacea.

Adiposity in Childhood

Q.—A woman has had a large abdomen and pendulous breasts since her youth; all kinds of treatment had no effect. Can anything be done to prevent her children, aged 7 and 5, from developing the same condition? They are already showing signs of adiposity—protruding abdomen, and, in the elder girl, developing breasts. They are healthy and normal otherwise, and do not overeat.

A.—A tendency to the condition described is determined genetically and cannot be avoided; nor, unfortunately, is there any endocrine hormone which fundamentally changes this innate endocrine constitution. Postural exercises will minimize the accompanying lordosis, which is part of the clinical syndrome, dieting is of limited value.

Effect of Oestradiol Benzoate in the Elderly

Q.—Could you tell me the effect of doses of oestradiol benzoate by injection on a woman of 70? I have taken these at intervals since 1924, and they have kept me far younger than my years; now I have been told that they may cause an ovarian growth.

A.—The action of oestrogens on the ovary is a depressant one and there is no reason to fear that they will cause an ovarian growth. Apart from effects on general metabolism and other endocrine glands their action is on the secondary sex organs, stimulating the Fallopian tubes, uterus, vagina, vulva, and breast. The effects vary with the dose, but there is a risk of endometrial hyperplasia and uterine haemorrhage and

possibly of carcinoma of the uterus, although this latter is proved. They might also stimulate the glandular tissue of breast to unnatural activity. Although in some cases no result may result or be apparent, it is generally believed to be wise to continue oestrogen therapy for long periods after the menopause. One of the disadvantages is that chronic oestrogen therapy makes the patient tolerant to it, and it is then difficult to discontinue it without precipitating severe menopausal symptoms. It is, moreover, doubtful whether any preservation of youth, except in respect of preventing atrophy of the secondary sex organs, can be ascribed to oestrogen therapy.

Multiple Boils

Q.—Does penicillin predispose to recurrence? What is the chance of breeding a strain resistant to penicillin in a case of recurrent boils? A male patient, aged 63, has had multiple boils for 18 months, due to Staph. aureus. He has had three courses of penicillin by injection, which temporarily cleared the boils; but they returned a few weeks after each course in spite of sterilizing all clothing. He is now having a course of autogenous vaccine, and the boils have developed again, also one large carbuncle, a month after beginning the course. What further treatment can be given?

A.—Penicillin certainly does not predispose to recurrence; on the other hand, penicillin treatment often breeds a resistant strain, which will remain insusceptible to further treatment. A further culture should be made and the present susceptibility of the staphylococcus to penicillin tested. Such a history as this in an elderly patient suggests an underlying cause of diminished resistance to infection, which may have to be dealt with before more specific treatment can succeed.

Penicillin for Vincent's Angina

Q.—Is there any treatment for severe Vincent's angina besides penicillin and local applications such as chromic acid? Is penicillin more effective in the form of a lozenge or given systemically?

A.—Before the introduction of penicillin it was usual to treat Vincent's angina with neoarsphenamine, of which even on injection of 0.45 g. was often followed by rapid recovery. In any case in which penicillin is proving ineffective arsenical should be tried. It has been the general experience that penicillin is the most effective treatment for this infection. In patients in whom angina is the salient feature parenteral administration of 15,000 to 20,000 units every three hours is probably best. Local applications of penicillin solution in concentrations of 500 to 1,000 units per ml. four times daily will also lead to healing of the ulcers. Pastilles or penicillin chewing-gum are most useful where gingivitis is the main disability. The time taken for healing varies from one to ten days, depending on the severity of the infection.

NOTES AND COMMENTS

Mumps at 80.—Dr. L. G. JACOB (Braeknall, Berks) writes: This week I was called by a woman to see her mother, as it was thought that she had mumps. The diagnosis was correct, but found the patient, quite cheerfully, doing the family washing. Her age is 80.

Disclaimer.—The Medical Committee of the Charterhouse Rheumatism Clinic, London, wish to dissociate themselves from the statements appearing in the Press in connexion with a visit to the Clinic by the Duchess of Gloucester. There is no foundation in statements suggesting knowledge of a potential new drug for the treatment of chronic rheumatic diseases, nor is any such preparation under investigation at the present time.

LONDON SATURDAY JUNE 19 1948

LONDON SATURDAY JUNE 19 1948

TERMS AND CONDITIONS OF SERVICE

regard will be had to the Spens Committee's report on specialists' remuneration.

Pending the date of operation of new scales the recent Revision of the Askwith Memorandum will continue to apply, in accordance with the agreement with the local authority associations.

Another item of importance which has been referred to the Subcommittee is the draft of the Regulations on transfer of officers and compensation, to be made by the Minister under Section 68 of the Act. The Standing Public Health Committee of the Association has been dealing with this up to now in conjunction with the Society of Medical Officers of Health. As a result of representations which have been made, from other quarters as well as medical, a new amended draft has been issued and is being considered by the Subcommittee.

CONSULTANTS AND SPECIALISTS IN THE NATIONAL HEALTH SERVICE: SUMMARY OF THE PRESENT POSITION IN ENGLAND AND WALES

With the reopening of discussions with the Ministry, a Public Health Subcommittee has again been appointed by the Negotiating Committee. The main question which is likely to occupy attention is future remuneration and conditions of service of medical officers, not only medical officers employed by the local health authorities in the National Health Service—i.e., County and County Borough Councils—but also those in the service of other local authorities. The Minister has recognized the principle of medical officers of all local authorities being dealt with at the same time by the same negotiating machinery as part of the general negotiating machinery that is being set up in the Health Service.

Proposals which were formulated two years ago on a basis of future negotiations are to be reviewed, and in this connexion

General Organization

Hospital and specialist services apart from teaching hospitals, are now being organized by Regional Hospital Boards, and for this purpose the country is divided into 14 hospital regions. The name and address of the Senior Administrative Medical Officer of each region is as follows.

Addresses. Senior Administrative Medical Officers and Secretaries of the Regional Hospital Boards

No. of Regional Hospital Board	Address of Board	S.A.M.O.	Secretary

* South East Metropolitan Area Transport H. Board—until further notice this Board is remaining at its old address: 27, Queen Anne Street, W.I. Tel. No. 2265

The hospitals, individually or in groups of varying sizes according to circumstances, will be administered by a Hospital Management Committee, which will appoint a secretary (medical or lay) and other administrative officials.

Thirty-six individual or grouped hospitals have been designated as teaching hospitals. These are independent of Regional Hospital Boards and will be administered by Boards of Governors.

The ownership of all voluntary and municipal hospitals will be transferred to the Minister on the appointed day, except for some 200 which the Minister has disclaimed because of their religious or other special character. These hospitals and their staffs will continue to function as now, outside the Service, though some may be in contractual relationship with Regional Boards.

Nursing-homes

The Minister is unable to give a general assurance that hospitals and nursing-homes not taken over on the appointed day or later established privately will not subsequently be the subject of compulsory purchase under the Act. He has pointed out, however, that the exclusion of some 200 hospitals from the Service is direct evidence to the contrary, since he would scarcely exclude a hospital first and then acquire it by purchase afterwards. He has further stated that the acquisition of private nursing-homes is not in prospect.

If subsequent to July 5 any private body were to contemplate spending money on a private hospital or home run for profit, and feared that the Minister would wait for it to exist and then use compulsory purchase powers on it, it should first discuss the project with the Minister at the time, and the Department would indicate its likely attitude straight away.

Hospital Staffs

The existing staffs of transferred hospitals will be taken over by Regional Hospital Boards and Boards of Governors of Teaching Hospitals on the appointed day. Full-time staffs will be transferred under the Act and will carry on under existing contracts. In the case of part-time staffs the Boards will offer interim contracts extending to March 31, 1949. It will not be possible for a part-time specialist to continue on the staff of a transferred hospital without entering into a contract, but it will be possible for him to enter into an engagement to perform services in an honorary capacity if he so elects.

After the appointed day the Boards will review the specialist services of their regions or hospitals and will no doubt create new appointments and terminate others. The Minister has indicated that if an appointment is terminated it is anticipated that the holder will normally be offered another post in the same hospital or at least in the same region. He has also stated that hospital staffs will have all normal remedies for unlawful dismissal and will be protected in addition to their medical committees by Whitley machinery. Whitley councils will be established for each broad professional group, and will contain representatives of the management on the one hand, and of the hospital staffs on the other. The Association is pressing for separate Whitley councils to deal with the medical profession, including hospital staffs. Medical committees are committees formed by medical staffs, and the Minister has agreed that it is desirable for the staff of every hospital or group to set up such a committee, and has asked Boards and Management Committees to give every help and encouragement.

New or vacant hospital and specialist appointments will be advertised in the medical press as at present, and specialists will accept them or not, as they choose; there is no compulsion, nor any power of compulsory transfer to other areas or hospitals. Junior appointments in non-teaching hospitals up to and including chief assistant or registrar will be made by Hospital Management Committees. Specialist appointments (including appointments in teaching hospitals) will be filled by the appropriate Boards on the recommendation of Advisory Appointments Committees, predominantly medical bodies which will be set up for the purpose. A practitioner will become a specialist in the Service by applying for and securing a specialist appointment. (The Association's Consultants' Roll has no connection with the National Health Service. It is a list of Consultants and Specialist members of the Association who are entitled to elect members of the Consultants and Specialists Central Council.)

Part-time Consultants and Specialists

It is anticipated that a large proportion of consultants and specialist appointments will continue to be part-time as at present and the Minister has given an assurance that he will exclude from Regulations to be made under the Act any provision for universal whole-time specialist service. A part-time specialist in the Service will be able to devote the remainder of his time to private specialist work outside the Service. A proportion of private pay-bed accommodation in hospitals will be preserved, and a part-time specialist will be entitled to treat private patients in these beds. Normally a maximum scale of fees will be laid down, but in a percentage (not yet settled) of the beds there will be no ceiling.

General-practitioner Consultants and Specialists

A part-time specialist in the Service will also be fully entitled to devote the remainder of his time to general practice, either within or outside the Service. A general-practitioner consultant, who wishes to enter the Service both as a general practitioner and as a consultant will enter his name as a general practitioner on the medical list of an Executive Council, and will also enter into contract as a consultant with a Regional Hospital Board. He will then qualify for compensation under the Act. Should he subsequently wish to devote himself entirely to consultant or specialist work, it will be open to him at any time after July 5 to give to his Executive Council three months' notice of retirement from general practice. This will in no way affect his compensation provided that he signified his intention of entering the Service as a general practitioner before July 5. A general-practitioner consultant in the Service will not be entitled to charge fees for any specialist service rendered to his own or his partner's public patients, except in pay-beds provided under Section 5 of the Act or in a registered nursing-home and provided he is on the staff of a hospital as a specialist furnishing treatment of the kind required by the patient.

Reference of Patients to Specialists

Patients will be referred to consultants or specialists very much as they are at present—i.e., they will be sent to the out-patient departments of hospitals accompanied by letters from their general practitioners. A domiciliary consulting service based on the hospitals will also be organized by Regional Hospital Boards to be available when the patient's condition makes a home visit essential. The Boards will make known to general practitioners which consultants are available, the days and times when they can be consulted, and the hospital through which their services can be obtained. As far as possible both for emergency and non-urgent calls the hospital will arrange for general practitioners to have the consultant of their choice.

Remuneration

The Minister announced to Parliament on June 3 that the Government had accepted the recommendation of the Spens Committee on the remuneration of consultants and specialists in principle. This report has been fully reviewed in the *Journal* and its recommendations are now being considered by the Association and by the Hospital and Specialists Service Subcommittees of the Negotiating Committee.

Early discussions will then take place with officials of the Ministry with a view to translating the recommendations into detailed terms and conditions of service for consultants and specialists taking part in the new Service.

These discussions will inevitably take some little time to complete, and in the meantime the position will be as follows

(1) Whole-time specialists transferred to Regional Boards or Boards of Governors will continue to receive the same remuneration and enjoy the same conditions as on transfer.

(2) Part-time specialists will receive £200 per annum for each half day per week given to hospital or other work in the service of the Board (other than domiciliary visits), up to a maximum of £1,600 per annum.

(3) In addition remuneration for domiciliary visits will be paid to those specialists who agree to make them, at the rates of four guineas for a consultation, five guineas for a visit involving minor operation, and ten guineas for a visit involving major operation, up to a maximum of 100 guineas in any one quarter.

The Minister has informed Parliament that these terms will be adjusted when the recommendations of the Spens Report

of the Medical Practices Committee
automatic except in any area where the number of doc

participating is already such that the Committee are satisfied that no more are needed or where more than one doctor seeks to fill the same vacancy and the Committee therefore have to decide.

One of the first duties of the Medical Practices Committee, shortly to be set up, will be a review of the distribution of general practitioners throughout the country. This review may show that certain areas are already over-doctored. Except in those areas, every doctor will be free to practise where he chooses and consent will be automatic except where there is more than one applicant for the vacancy. In these areas a doctor can undertake private practice without permission of any sort.

A doctor who already has a National Health Insurance practice, and who decides to take part in the new scheme, will carry his present insurance patients with him into the new arrangements except so far as any of them express a desire to change to another doctor. No special steps need be taken in such cases either by doctor or patient—except for the doctor to see that he is included in the appropriate medical list before July 5, 1948. (Similarly, insured members of "approved institutions" under the Insurance scheme—e.g., medical aid societies—will be regarded (unless they express a desire to change) as continuing with the doctors employed by those institutions, if the latter are included in the Executive Council's list before July 5.) In all these cases there is *no* need for the patients to make any formal application for acceptance by the doctor, or for the doctor to take any formal steps to accept them.

Any doctor can at any time decline to continue to undertake the medical care of any particular patient except while the patient is actually under treatment by him.

Anyone only temporarily resident in any area can ask any doctor participating in the scheme in that area to accept him for temporary medical care. He will still remain nevertheless on his own doctor's list in his normal home area. In these circumstances the practitioner rendering temporary medical care will be eligible for a temporary residents fee.

Size of Lists

Normally, the maximum number of people who can be accepted under the new arrangements by a single doctor will be 4,000. In a partnership individual partners can accept up to 5,000, so long as the average per partner is not more than 1,000. For each employed assistant, up to 2,400 more people can be accepted. But at the outset these maxima may have to be exceeded in certain cases to enable patients who so wish to continue with their present doctors in the new scheme.

Range of Medical Care Involved

A doctor accepting patients in the new scheme will be expected to give them all proper and necessary advice and treatment, but not any treatment involving special skill or experience not possessed by general practitioners as a class, though in an emergency he should give whatever treatment he thinks to be in the best interests of the patient.

Surgery Hours : Visiting

Doctors are asked to give their proposed surgery hours when seeking inclusion in the Executive Council's medical list. They should also show in what district they propose to participate in the new scheme. Within that district it will be their responsibility to visit and treat any of their patients whose condition so requires. If they accept people resident outside that district it will be their responsibility similarly to visit those people as necessary.

Certification

The Minister has appointed an interdepartmental committee to advise how far the number of medical certificates can be reduced. The Association is presenting evidence to this committee and the interests of practitioners are being carefully watched.

Drugs

Doctors in urban areas will not usually supply drugs or appliances to their patients, except those required immediately or where a supply can be otherwise obtained. They will normally give prescriptions for those drugs and appliances which are necessary for the treatment of their patients.

There will be no restriction on the drugs which may be ordered for free supply for the proper treatment of any patient, so long as they are medically necessary. A *National Wholesaler's Formulary* has been prepared to assist doctors in their prescribing by listing various preparations by short titles.

In rural areas the Executive Council may arrange with, or in certain circumstances may require, doctors themselves to dispense drugs and supply appliances for patients who would otherwise have serious difficulty in obtaining them or who live at least a mile from the nearest chemist. Doctors are asked to indicate their willingness to provide this service to particular patients when sending to the Executive Council the acceptance forms or medical cards given to them by these patients.

Private Fees

A doctor will not be able to charge fees for any treatment, whether or not it is within the range of general medical care undertaken by him, to patients who have been accepted by him on his list (or the list of a partner or assistant) except:

- by way of deposit if they claim to be on his list and cannot produce evidence of that fact in the form of their medical card; (patients may claim back these deposits);
- under the Road Traffic Act, 1934, for attending a person involved in an accident;
- for specialist treatment in pay-beds provided under Section 5 of the National Health Service Act or in a registered nursing-home, provided that he is on the staff of a hospital as a specialist giving treatment of the kind required by the patient.

He will be able to receive payment from Regional Hospital Boards, local authorities, or other employing bodies for services carried out on their behalf or by agreement with them. He will also be entirely free to treat privately, and charge fees to, any persons not on his list or on the list of his partner or assistant.

Personal Attendance

Doctors will be expected to give personal attendance to patients accepted by them, unless prevented from doing so by absence from home, illness, or other reasonable cause, in which case they will be expected to arrange for a deputy. A partner, assistant, or locumtenent can act as the deputy.

Disputes Procedure

Complaints that a doctor has not complied with the general conditions under which the care of patients is undertaken in the new scheme will (except where the considerations are wholly professional) come before the Medical Service Committee of the Executive Council—on lines broadly similar to the past. The Committee will consist of a chairman, three medical members (appointed by the Local Medical Committee), and three lay members. Their report will go to the Executive Council, who if they find the doctor has been at fault, may recommend that a sum should be withheld from his remuneration. The doctor may appeal to the Minister, who for certain more serious types of case will before deciding that money should be withheld consult a special Medical Advisory Committee.

Complaints involving wholly professional considerations (e.g. where unnecessarily costly prescribing, or failure to keep proper clinical records, is alleged) will be dealt with in the first instance by the Local Medical Committee.

Representations that a doctor's name ought no longer to be included in a medical list will be considered by a special Tribunal, consisting of a lawyer of standing, appointed as chairman by the Lord Chancellor, a lay member, and a medical member selected from a panel of available members having regard to his special experience in the particular issue before the Tribunal.

The Tribunal alone can decide that his name should be removed, and if they so decide the doctor can appeal to the Minister to reverse the decision. If they decide he should remain on the list the Minister cannot intervene. Before reaching his decision on an appeal the Minister must consult the special Medical Advisory Committee mentioned earlier.

Partnerships

The Minister has stated that partnership agreements existing before July 5, 1948, are not affected by the National Health Service Act and that clauses relating to buying and selling between partners of shares in the goodwill of the partnership

or options to purchase such shares, will remain operative. The Association's legal advisers have cast doubt on this interpretation of the Act, and doubt there must remain until the committee appointed for the purpose of clarifying this issue has reported. The Minister has undertaken to amend the Act if in the light of the committee's report he finds that partners in existing partnerships might be unfairly prejudiced. If these findings are not available before the appointed day the Minister has given an assurance that any subsequent legislation in clarification of the position will, so far as is at all practicable, be made retrospective. He has also stated that where a partner in good faith joins the Service and subsequently finds himself placed in an unfavourable position his claims for adjustment will be sympathetically reviewed.

While no guidance can be given to practitioners in partnership at the present time, every effort will be made to have the position clarified before the appointed day.

All practitioners will be free to choose their colleagues, partners, and assistants unless the area requires no more or the Regulations on the employment of assistants are contravened. Where more than one doctor wishes to be the partner or assistant in question the Medical Practices Committee will be asked to observe the wishes of the doctors concerned. (The approval of the Medical Practices Committee is only required for an assistant if it is intended that the assistant's name should be included in the medical list for the area.)

Practitioners needing advice on partnership problems should write to Headquarters for further information.

Partnerships and groups will be entirely free to allocate duties and responsibilities as now. Doctors will be free to decide when an additional partner or assistant is necessary, subject to the cases where the Medical Practices Committee decide that no additional doctor at all is needed in the area and subject to the conditions about assistants. A retiring doctor's views as to his successor would be taken into account by the local Executive Council, but that Council must ultimately decide what to advise the Medical Practices Committee about the new practitioner to come to the area.

Compensation

Doctors taking part in the new scheme will not be able to sell their practices, but those whose names are on a medical list by July 5, 1948, will be entitled to compensation. The actual amount of compensation payable cannot be calculated until it is known how many doctors have entered the Service by that date, and it is therefore not possible to estimate how much an individual doctor will receive. It is contemplated that generally speaking, the total amount will be divided among the doctors entitled to participate in proportion to their gross incomes from general medical practice in the last convenient accounting year before July 5.

Compensation will be assessed as soon as all the relevant information is available. Normally it will be paid when a doctor retires from practice or dies, and meantime interest at 2½ per annum will be paid, but early payment may be made in cases of hardship.

As it will not be possible to assess individual compensation for some little time, the Minister proposes to deal with urgent cases of hardship and cases coming under Section 37 by payments on account, final settlement being reached as soon as practicable. A practitioner whose name is included on a medical list by July 5, 1948, can subsequently retire with compensation after giving the statutory period of three months' notice. A practitioner in these circumstances is not debarred from engaging in general or specialist practice outside the public service in the same area or in any other area, though he will be precluded from subsequently selling his practice in the same area.

Local Medical Committees

The Amending Bill will empower Executive Councils, where the local practitioners agree, to cover the administrative costs of the Local Medical Committee by the necessary deduction from the practitioners' remuneration.

Freedom of Speech and Publication

Regional Hospital Boards and Management Committees have already been told by the Minister that no prior consent should be required to any publication as part of the conditions of service of consultants. No express provision need be made for

general practitioners, as under the general terms of service it would be impossible for anyone to require consent, as there is no power to do so.

Contributions to National Insurance Scheme

All practitioners on Executive Council lists will, so far as their general practice is concerned, be deemed to be self-employed persons under the meaning of the National Insurance Act, but special considerations may apply where such practitioners also hold hospital, etc., appointments.

Income Tax

Income tax will be assessed under Schedule D as at present.

REMUNERATION OF INDUSTRIAL MEDICAL OFFICERS

In para. 58 of the Annual Report of Council (Supplement April 10, p. 77) it is stated that the Council has laid down principles and recommended rates of remuneration for whole-time and part-time medical officers employed in industry. The scales are now published below for the information of employing authorities and industrial medical officers. Attention is drawn to the fact that these are minimum scales, and that the Council is strongly of the opinion that all industrial medical officers should be entitled either to regular increments or to periodic review of salary.

Whole-time Salaries

1 The commencing salary of a *whole-time* industrial medical officer in charge, single-handed or with assistants, should range from £1,000 to £1,750 per annum according to the degree of responsibility, qualifications and experience, and age.

2 The minimum commencing salary of an *assistant* industrial medical officer should be £850 per annum according to the degree of responsibility and character and extent of the duties.

3 The industrial medical officer should be entitled to expect either regular increments or periodic review of salary.

Part-time Salaries

(The following scale is minimum and applies to *part-time* appointments where no *full-time* medical officer is employed.)

- 1 Remuneration should be by salary on an annual basis.
- 2 Where the average time spent (including travelling time) is less than one hour per week, the salary should be £75 per annum.
- 3 Where remuneration is on an hour-per-week basis and the time spent exceeds one hour per week, payment should be made on the following basis:

Hours	Annual Salary	Hours	Annual Salary
1	£ 75	10	
2	150	11	£ 675-£ 725
3	225	12	
4		13	£ 750-£ 825
5	300-375	14	
6		15	
7			
8	450-525		
9			

4. Where remuneration is on a sessional or visit basis, payment should be on the following basis:

No of Sessions or Visits	Annual Salary
	£
1	150-225
2	300-375
3	450-525
4	600-675
5	750-825

5. The above scales are intended to include work inside and outside the industrial establishment and cover not only routine work but also telephone consultations, preparation of memoranda, advice on Government publications, etc.

6. A visit or session is reckoned as being normally of 1½ to 2½ hours' duration.

7. Where an industrial medical officer is employed and paid on a sessional basis and is required to travel beyond a radius of two miles in the course of his duties a mileage rate of 1s. a mile each way should be paid.

8. Where the appointment involves more than 15 hours per week or more than five sessions each of not more than 2½ hours' duration the appointment of a whole-time officer should be considered.

RECRUITMENT OF YOUNG PRACTITIONERS

The Central Medical War Committee is issuing the following circular to hospital authorities in England and Wales. A similar circular will be issued in Scotland by the Scottish C.M.W.C.

DEAR SIR,

Recruitment from "A" Posts

1. The Central Medical War Committee has recently experienced great difficulty in obtaining the numbers of medical recruits required by H.M. Forces and it has become clear that exceptional measures are necessary if the recruitment of medical practitioners during the remainder of this year is not to fall far short of the requirements of the Services.

2. On the recommendation of the Medical Priority Committee the Minister of Health, with the concurrence of the Secretary of State for Scotland, has now instructed the Central Medical War Committee that young practitioners who are liable for military service and who complete a six months' tenure of "A" posts in hospitals during the second half of 1948 must be recruited on the termination of their "A" appointments and must not be permitted to proceed to "B2" posts. Appeals for deferment will not be considered by the Central Medical War Committee in such cases, but a practitioner will retain the right to appeal against recruitment on the ground of conscience and to appeal for postponement of recruitment on the ground of exceptional personal hardship.

3. A practitioner whose "A" appointment terminates before he has occupied it for six months will be permitted (subject to what is said in para. 5 below) to occupy another "A" appointment for the remainder of the six months' period, but will not be allowed to proceed to a "B2" post. In the exceptional case in which the first post held after medical qualification is not in the "A" category, the practitioner will be recruited after a six months' tenure of the post.

4. This is to be regarded as a temporary emergency measure, and the need for its continuance will be reviewed towards the end of the year. The Central Medical War Committee will be glad if hospital authorities will kindly arrange for it to be brought to the notice of those practitioners in their employment who will be affected by it.

Recruitment before the 26th Birthday

5. I am asked to inform you also that in future all practitioners, liable for military service, who are below the age of 26 on their admission to the *Medical Register* will be recruited before they reach their 26th birthday, even if this should prevent them from completing the normal period of six months in an "A" post, or from occupying an "A" post at all. It follows that a hospital which appoints to an "A" post a practitioner who will attain the age of 26 during the six months following the commencement of the appointment will not be able to retain his services for the normal period. The urgent need to increase the number of recruits makes it necessary to adopt this procedure, as a practitioner granted deferment in an "A" post beyond his 26th birthday is no longer liable to compulsory recruitment. The same procedure will be adopted in the exceptional case of the newly qualified practitioner approaching the age of 26 who is appointed to a "B2" or other post without having first held an "A" appointment. In such a case the practitioner will not be permitted to hold the post for six months if this would prevent his recruitment being effected before his 26th birthday.

Summary

6. (i) A young practitioner, liable for military service, who completes a six months' tenure of one or more "A" posts on or after July 1, 1948, will be recruited forthwith and will be allowed to appeal only on the ground of conscience or on the ground of exceptional personal hardship. Similarly, a practitioner whose first post after medical qualification is not in the "A" category will be recruited after he has held the post for six months. This modification of the present regulations governing deferment of recruitment will be reviewed towards the end of 1949.

(ii) A young practitioner below the age of 26, and liable for military service, will not in future be allowed to hold an "A" or other post, or to complete the normal tenure of the post, if this would prevent his recruitment being effected before his 26th birthday.

(iii) Hospital authorities are invited to assist the Central Medical War Committee by bringing these decisions to the notice of practitioners in their employment who will be affected by them.

Yours faithfully,

CHARLES HILL,
Secretary.

NATIONAL HEALTH SERVICE

Supplementary Ophthalmic Services: Notice to Ophthalmologists

It is understood that the Ophthalmic Services Committee of each Executive Council will be required to publish a list of medical practitioners and opticians, having the prescribed qualifications, who undertake to test sight on the terms obtaining in the Committee's area. The expression "medical practitioner having the prescribed qualifications" means a medical practitioner who has:

"(a) completed an academic or postgraduate course in ophthalmology approved by the Committee hereinafter in this paragraph mentioned, and received a diploma or certificate in respect of this course; or

(b) held for a period of two years an appointment as an ophthalmic surgeon or assistant ophthalmic surgeon on the staff of an eye hospital or a hospital having a special eye department; or

(c) held any appointment for a period of two years affording special opportunities for acquiring the necessary skill and experience of the kind required for the services to be rendered; or

(d) had immediately before the appointed day his name included in the list of medical practitioners prepared by either the B.M.A., the National Ophthalmic Treatment Board, or the Incorporated Ophthalmic Council, for use by Approved Societies for the purpose of ophthalmic benefit under the National Health Insurance Act 1936;

and who shall, to the satisfaction of the Minister, acting on the advice of a Committee to be recognized by him for the purpose of approving such qualifications, have had adequate, *including recent, experience.*"

The central professional Committee referred to above has been recognized by the Minister and is composed of practitioners nominated by the B.M.A. and the Faculty of Ophthalmologists. This Committee has the duty of compiling a central list of medical practitioners having the prescribed qualifications. The Committee therefore invites applications from all ophthalmic medical practitioners to be included in the central list which is an essential preliminary to inclusion in local lists for which separate application must be made to the Ophthalmic Services Committees of the Executive Councils concerned.

Inclusion in the central list is entirely without prejudice to future action and it will be open to every practitioner to decide, when he knows the terms of service, whether he will take part in the Supplementary Ophthalmic Service or not. Ophthalmic practitioners should not, however, await the publication of the terms of service before applying for recognition by the central committee.

All ophthalmic practitioners are therefore requested to apply as soon as possible to the Secretary, Ophthalmic Qualifications Committee, B.M.A. House, Tavistock Square, W.C.1 giving the necessary evidence that they comply with the criteria outlined above. It is particularly important that details of recent experience should be included.

CORRECTIONS TO PROGRAMME OF ANNUAL MEETING

In the section of Anatomy and Anthropology Dr. D. V. Davie is the only Honorary Secretary.

In the section of Neurology and Psychiatry Dr. Denis Williams F.R.C.P., and Mrs. A. V. Jhill have been invited to speak at the discussion on "The Early Recognition and Management of Senile Deterioration."

THE B.M.A. AND TRADE UNION LAW

1. During the period of reconstruction which followed the war of 1914-18 there arose among a section of the medical profession a demand for the reorganization of the Association. The advocates of this policy contended that the Association was organized on the wrong lines and that to be really effective the body representative of the profession should modify its constitution and become a registered trade union. There are signs of a revival of the controversy of 25 years ago. There is, however, some misunderstanding of the advantages and disadvantages of the trade union method of organization. Some believe that it is the short cut to the millennium; others believe that registration as a trade union involves affiliation with the T.U.C. and entanglement in political strife.

2. The B.M.A. is not a trade union. It is a limited company with the licence of the Board of Trade to omit the word "limited" from its title, being an association formed for scientific purposes and not for profit. Its primary object is "to promote the medical and allied sciences and to maintain the honour and interests of the medical profession" Its Memorandum of Association provides

(1) that "the Association shall not support with its funds any object or endeavour to impose on or procure to be observed by its members or others any regulation restriction or condition, which if an object of the Association would make it a trade union"

(2) that the income and property of the Association "shall be applied solely towards the promotion of the objects of the Association as set forth in this Memorandum of Association, and no portion thereof shall be paid or transferred directly or indirectly by way of dividend or bonus or otherwise, by way of profit to the persons who at any time are or have been Members of the Association" with the exception of payment of remuneration in return for services rendered to the Association.

Opinion of Counsel

3. In 1946, when the Trade Disputes and Trade Union Act 1927, was repealed and certain local authorities sought to enforce the "closed shop" principle the Association reviewed its position and constitution in relation to trade union law generally and obtained legal advice on a number of points including (a) the advantages and disadvantages that would accrue if the Association sought to become a registered trade union or a certificated but unregistered trade union, and (b) the alterations in the constitution of the Association which would be required to enable the Association to become a trade union.

The joint opinion of Mr Cecil R. Havers K.C., and Mr M. L. Gedge is given below

(1) In our opinion there is no means of placing the contributions of the British Medical Association so as to serve the Association into a trade union. The Association is a voluntary association under the Companies Act, 1929, and is not, and cannot be, a trade union having regard both to the provisions of its Memorandum of Association providing the Association having trade union objects and to section 2 of the Trade Union Act, 1871, and section 332 (7) of the Companies Act, 1929, which provide that the registration of any trade union under the Companies Act shall be:

(2) It follows from the above opinion that if it is desired to form a trade union consisting of members of the medical profession, this can only be done by forming a new body independent of the Association. We consider that the latter course will be without difficulty in establishing such a body.

A trade union for the purpose of the Trade Union Act 1913, means any combination (whether temporary or permanent) the principal objects of which are under its constitution or objects (Trade Union Act 1913, section 2 (1)) those objects being (section 1 (2)) "the regulation of the relations between workmen and masters, or between workmen and workmen, between masters and masters, or the imposing of restrictive conditions on the conduct of any trade or business, and also the promotion of benefits to members."

Members of the medical profession are not in our opinion either "masters" or "workmen" whether carrying on business on their own account or employed by a local or other public authority, and in our opinion the only effective statutory object which could be adopted would be "the imposing of restrictive conditions on the conduct of their business" and "the promotion of benefits to members," that is to say, those would have to be the principal objects under the constitution of a "medical" trade union.

The fact that a combination has under its constitution objects or powers other than statutory objects does not prevent the com-

bination being a trade union for the purposes of the Trade Union Acts, 1871 to 1906 (Trade Union Act, 1913, section (1) (1)), so long as the combination is a trade union under the Act of 1913, but under section 2 (2) of the Act of 1913 the Registrar can refuse to register any combination as a trade union unless in his opinion, having regard to the constitution of the combination, its principal objects are statutory objects, and the Registrar may under that subsection withdraw the certificate of registration of a registered trade union if in his opinion the principal objects for which the union is actually carried on are not statutory objects.

We stress this point because we anticipate that, if a "medical" trade union were to be formed, then although the principal object might *prima facie* appear to be the two objects we have mentioned, and although the certificate of the Registrar that the union was a trade union would so long as it was in force be conclusive for all purposes (Trade Union Act, 1913, section 2 (5)), there might be some danger of a member seeking to establish that the principal objects as actually carried on were not the stated objects, so as to cause the Registrar to withdraw his certificate.

(3) We are asked to advise as to the advantages and disadvantages of forming a medical trade union which members of the Association might join.

One suggestion we have considered is that the Association should be wound up and the new body formed as a trade union which all members of the Association could join.

We were informed in consultation that such a course is entirely impracticable; whilst, apart from practical disadvantages, there would be the additional difficulty that it is impossible to transfer the assets of the Association to the new body, these assets in a winding up of the Association being the property of the members.

There may, however, be practical advantages in forming a medical trade union independent of the Association, which managers could not see the great advantage being that it is not open to his authority made in a condition of employment, a member of the medical profession may be a member of a trade union in connection which is liable to be unfilled upon the threat of a Trade Disputes Act, 1927, then there would be a trade union already made" for the members of a joint Association, and in cases in the formation of a trade union are the "common rule" in the Act (Trade Disputes Act 1916, section 4 and 5 and 6, 1927, and 1928)

The disadvantages as we see them are: (1) a signature. We were informed in consultation that many members of the Association might object to the formation of a more wide union, while in any event the formation of a separate one must tend towards the creation of a divided organization and be harmful to the Association.

For the reasons stated above, the Commission is of the opinion that the provisions which might be disallowed in the submission of the Registrar of Donations of Receipts, funds, effects, and expenditures, and on balance, our view is that the advantage of having a fund union available for members to join would outweigh the potential disadvantages; no such union should be formed.

of the practical disadvantages: no such union should be formed. We have assumed that a trade union would be formed and would be registered under the Trade Union Acts, 1871 to 1913, so as to establish it on the statutes, statutory footing and then to seek recognition in the Trades Union Congress. It is of course possible to form an unregistered trade union but we doubt whether this course would be of any practical advantage. It would in our opinion in any event then be necessary to apply to the Registrar under section 2(3) of the Trade Union Act, 1913, for his certificate that the union is a trade union, which certificate could be withdrawn on the application of any person if the Registrar were satisfied that the principal objects are not statutory objects or that the union is not actually formed on for those objects. But even if such certificate were granted the practical disadvantage would remain that an *unregistered* trade union would have no status in the trade union world.

Summary

It will be seen that counsel expressed the view that members of the medical profession are neither masters nor workmen within the meaning of the Trade Union Acts. The medical profession could not satisfy the first of the "statutory objects"—namely, the regulation of the relations between workmen and masters, etc. The only effective "statutory objects" which could be adopted would be the imposing of restrictive conditions on the conduct of their business and the provision of benefits to members. These would have to be the *principal* objects under the constitution of a medical trade union. Thus, the main question is whether a body representative of doctors can properly adopt as one of its *principal* objects the imposition of restrictive conditions on the professional work of its members. For example, can it properly withdraw its services from the public? For the imposition of restrictive conditions to be one

of the objects would not suffice: it would have to be a principal object to satisfy trade union law.

On the other hand it has been demonstrated, both in connexion with the "closed shop" controversy and the question of acceptance of service under the National Health Service Acts, that the two limitations on the use of its funds imposed by the Association's present constitution (see para. 2 above) render it extremely difficult for the Association as such to administer anything in the nature of a fighting fund and impossible to reimburse—from the Association's funds—loyal members of the Association for any loss they might suffer in following the Association's policy. It was for this reason that the Independence Fund was established.

BRITISH MEDICAL ASSOCIATION

ANNUAL REPRESENTATIVE MEETING, 1948

MOTIONS AND AMENDMENTS BY DIVISIONS AND BRANCHES

National Health Service

Motion by BRADFORD: That this meeting views with grave concern the non-implementation of the general practitioner Spens Report.

Motion by HEXHAM: That this meeting is concerned at the lapsing of the Spens recommendations in relation to remuneration, and the apparent absence of consideration of the betterment clause of the Spens Report in the scale of remuneration proposed by the Minister.

Motion by CARDIFF: That the Mileage Fund, and the Regulations connected therewith under the present Act, be reviewed in their application to the new Act.

Motion by NEWCASTLE-UPON-TYNE: That the mileage fees for general practitioners should be reconsidered so that a general practitioner in any area should be entitled to charge mileage fees for a State patient on his list, even though that patient may be within two miles of another State doctor.

Motion by EAST HERTS: That the question of remuneration of general practitioners on the staff of cottage hospitals be brought to the notice of the Minister.

Motion by HEXHAM: That this meeting views with considerable dismay the indefinite postponement of health centres, and the complacency with which this postponement has been accepted by the profession.

Inasmuch as the original conception of a State Health Service was based on the health centre idea, with its improved amenities and the lessening of the burden placed on the doctor's household, it is considered that the construction of these centres should be expedited with urgent priority.

Motion by HEXHAM: That no doctor qualified in medicine should be required to apply to any appointed Body to confirm his qualifications to practise midwifery.

That it should be the inherent right of any doctor entering the Scheme to have his name placed on the Obstetric List if he so desires and that there should be a universal rate of payment.

Motion by EAST HERTS: That every patient who exercises his right to obtain his medical advice outside the scheme should nevertheless not have to forgo the benefits of the pharmaceutical service.

Motion by LEICESTERSHIRE AND RUTLAND: That private patients of practitioners working under the National Health Service should be allowed to obtain all drugs and appliances free of cost, it being realized that their contributions have entitled them to receive all the benefits of the Service.

Motion by MID-ESSEX: That to safeguard the profession legislation shall be introduced into the Amending Act so that the medical practitioners appointed to the Central Council, the Regional Board, and the Local Medical Authority shall be by democratic election by the medical profession and not nomination by the Minister.

Motion by CITY OF EDINBURGH: That radiologists, as registered medical practitioners, should have the right to join the National Health Service in their own sphere, and to receive remuneration in view of their expensive equipment.

Motion by LIVERPOOL: That the general practitioners be assured of an automatic rise in capitation fees in step with any increase in the cost of living or any increase in the number of doctors in the State pool.

Motion by LIVERPOOL: That this meeting considers that the time has now come to negotiate the terms of service for all medical hospitals staffs not covered by the Spens Report. The negotiation should be based on the scales of salaries approved by Council on June 5, 1946.

Motion by LIVERPOOL: That the official working hours of doctors should be limited to (a) a 40-hour week in conformity with the limitation of working hours that applies to other members of the community, and that work performed at times outside a recognized working period should be paid for at an increased rate or that such times should be available for work at fees to be arranged privately between patient and doctor;

(b) That in order that doctors may devote themselves to clinical work salaries of receptionists and clerical assistants be provided by the State.

(c) That as hospital accommodation under the National Health Scheme is increased the proportion of private beds be increased *pari passu*.

Motion by HENDON: That the Representative Body is of opinion that compulsory vaccination should be restored, and that the Minister of Health be advised accordingly.

Future Organization of the Profession

Motion by NEWCASTLE-UPON-TYNE: That the B.M.A. should devise some method whereby it can assume trade union status and so be in a better position to protect the interests of the profession.

Motion by PERTH: That in view of the introduction of the National Health Service on July 5, with the inevitable alteration in the status and outlook of the medical profession, and in order to safeguard its working conditions and remuneration, steps be taken to form a trade union of registered medical practitioners.

Motion by NORTH GLAMORGAN AND BRECKNOCK: That immediate steps be taken to draw up plans for modifying or adding to the Association's structure so that, if the necessity arose, it could effectively take action to protect the interests of the profession.

Motion by BOURNEMOUTH: That the constitution of the Association be reviewed to determine whether the organization in Great Britain should be altered (i) to provide a new basis of representation of members and (ii) to further such collective negotiation and action by the Association as the institution of the National Health Service may make desirable.

Motion by READING: That it be referred to the Council to investigate the best means of protecting the interests of the profession by guild or otherwise.

Motion by DERBY: That this Representative Body is of the opinion that, having regard to the increasing need for safeguarding professional freedom, the Independence Committee organization should not, under any circumstances, be discontinued.

Motion by NEWCASTLE-UPON-TYNE: That some means should be devised whereby a small part of the B.M.A. annual subscriptions should in future be earmarked as a fighting fund.

Motion by LEICESTERSHIRE AND RUTLAND: That the National Insurance Defence Trust Fund be continued, and that all taking part in the National Health Service be asked to subscribe by means of a voluntary levy.

GENERAL PRACTICE

Recruiting Medical Boards

Motion by GATESHEAD: That in view of the complicated system of classification recently introduced a considerable reduction should be made in the number of candidates called for examination by both male and female boards.

Night Visits

Motion by GATESHEAD: That in Minute 67 of A.R.M., 1947, the following should be substituted for Part (b). That any

JUNE 19, 1948

A.R.M., 1948: MOTIONS AND AMENDMENTS

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL

visit between the hours of 9 a.m. and 8 p.m. on any weekday should be considered a day visit and that any visit between 9 p.m. and 8 a.m. the following weekday, or between 9 p.m. on Saturday and 8 a.m. on Monday shall be considered a night visit.

Medical Examination of Intending Emigrants

Motion by DERBY: That with regard to medical examination of intending emigrants this meeting wholeheartedly supports the Council in its efforts to obtain an upward revision of the fee paid to a minimum of £1 11s 6d, and regards such revision as long overdue

Allowances to Medical Witnesses

Motion by LEICESTERSHIRE AND RUTLAND: That the Association continues to press with all its powers for the adoption of the increased fees and allowances which have been recommended by the Departmental Committee

Certification under National Health Service Act

Amendment by GATEHEAD: That the words "as provided by the National Insurance Act" be inserted after the word "benefit" in subheading (a) in the following recommendation: (a) "That the obligation placed upon a practitioner by Regulations under the National Health Service Act to furnish to patients seeking to receive treatment in accordance with the provisions of the Act be limited to such certificates as are necessary to make a claim (a) for sickness and disablement benefit, (b) for essential medical appliances, and (c) for special treatment under the National Health Service."

Amendment by GATEHEAD: That paragraph (d) be omitted from the following recommendation

"Recommendation D—That a certificate at any time written by a practitioner who has seen a patient regarding employment, and that the Health Insurance Act, is satisfied that his patient should at any time after the certificate valid for a period governing the reissue of additional supplies of ration books with a discretion on the condition of his patient, be required to issue a certificate to the private or Governmental agency the first and second

Motion by GATESHEAD

and highly desirable to secure the benefit under the National Insurance Act, without the necessity of the certificate of the

Amendment by READING

Council's proposals for the use of all National Insurance Act, without the necessity of the certificate of the

Health Service certificate

amended to read:

representations to the allotment of basic petrol purposes.

Amendment by GREENWICH AND DEPTFORD

ing is not satisfied that there is any improvement in the position

in regard to the obtaining of doctors' cars and expresses dissatisfaction with Council's statement, and urges the Council to secure definite priority

Medical Examinations for Life Insurance

Amendment by GREENWICH AND DEPTFORD: That with reference to para. 26 of Council's report the following words be inserted before "10s 6d" in the penultimate line "not less than"

Conferences

Amendment by SWANSEA AND SOUTH STAFFORDSHIRE: That the following para. (iv) of the Council's recommendation on Merituary Accommodation and Part-time Practice be amended

That measures be established under the control of the Council with accommodation and a separate venal system of running water, and a supply of running water, and a proper collection of refuse, and that the assistance of the Council be obtained for the purpose of the central management of the Council's

Amendment by SWANSEA AND SOUTH STAFFORDSHIRE

That the following para. (iv) of the Council's recommendation on Merituary Accommodation and Part-time Practice be amended

Amendment by SOUTH STAFFORDSHIRE

That the following para. (iv) of the Council's recommendation on Merituary Accommodation and Part-time Practice be amended

Amendment by GREENWICH AND DEPTFORD

That the following para. (iv) of the Council's recommendation on Merituary Accommodation and Part-time Practice be amended

CONSULTANTS AND SPECIALISTS

Regional Consultants and Specialists Committee and establish a Regional Consultants and Specialists Committee

Amendment by NEWCASTLE-UPON-TYNE: That in para. 60, the word "more" be substituted for "less" in the sentence to read

The Council proposes that not more than one member of those Regional Consultants and Specialists Committees by the staffs of the hospitals should be part-time consultants and specialists

Amendment by NEWCASTLE-UPON-TYNE: That in para. 61, the word "more" be substituted for "less" in the sentence to read

12-20 of whom not more than a quarter shall be part-time consultants and specialists

Amendment by SOUTHPORT: That para. 61 of the Council's report be amended by omitting the following words:

61 (1)

(i) (a)

such hospital(s) and are in consulting or specialist practice in the Region"

Amendment by SOUTHPORT: That para. 61 of the Council's report be amended by omitting the following words:

61 (1)

(i) (a)

a hospital other than a teaching hospital and are in consulting or specialist practice in the Region."

Motion by DERBY: That this meeting urges the Council to proceed immediately with the setting up of Regional Consultant and Specialist Committees.

HOSPITALS

The Position of the Medical Superintendent

Motion by LANARKSHIRE: That this Meeting reaffirms the previous decision of the Representative Body that in most instances the medical superintendent is recognized as the administrative head of the hospital and that in any final settlement arranged with the Government the B.M.A. will ensure that this principle is maintained and that terms and conditions of service of these officers shall be subject to negotiations.

PUBLIC HEALTH

Salaries in Public Health Service

Motion by GATESHEAD: Section 81, Annual Report of Council. That in view of the present value of the pound as compared with its value in 1939 the percentage increases in the salaries of whole-time medical officers of health are still inadequate.

Examination of Municipal Employees

Motion by GATESHEAD: That it should not be part of the duties of the public health staff to examine municipal employees for superannuation.

ORGANIZATION

Election of Council

Motion by PLYMOUTH: That Council be asked to report progress on that part of the Plymouth resolution adopted by A.R.M. in 1943, that consideration be given at an early moment to the election of Council on a more direct and better geographical basis.

Expenses of Representatives

Motion by PLYMOUTH: In order to ensure that suitable Representatives should not be prevented from attending meetings on the score of cost, reasonable out-of-pocket expenses in addition to first-class railway allowance should be paid by the Association, even if the expenditure should necessitate an increase in the annual membership subscription.

OTHER MOTIONS

Motion by NEWCASTLE-UPON-TYNE: That every session done by a practitioner should be paid for at full rate with no limitation of the number of sessions undertaken.

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

Metropolitan Borough Councils.—Fulham, Hackney, Poplar.

Non-County Borough Councils.—Dartford, Radcliffe (limited to future appointments), Tottenham, Wallsend.

Urban District Councils.—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Portslade, Redditch (restricted to new appointments), Tyldesley.

EX-I.M.S. OFFICERS AND THE COLONIAL SERVICE

The Armed Forces Committee of the B.M.A. has now been informed by the Commonwealth Relations Office that Kenya, Tanganyika, Northern Rhodesia, and Zanzibar have agreed to accept the terms reported in the *Supplement* of Feb. 28 (p. 35):

Service since appointment to the I.M.S. will be regarded as the equivalent of service in the Colonial Medical Service for the purposes of starting salary. Officers will enter the salary scale of Medical Officer in the Colony to which they are appointed at the point they would have reached if they had been appointed to the Colony at the time of entering the I.M.S. If such service exceeds the time required to reach the maximum of the Medical Officers' scale, they will enter at the maximum.

The Governments of Uganda and Nyasaland have not agreed to accept these terms, and except at the express wish of a candidate who has full knowledge of the rules governing starting salary in those territories the Colonial Office does not intend

All Governments, with the exception of the Federation of Malaya, have agreed that seniority should be determined age in accordance with the relevant section of the Colonial Office pamphlet R.D.W.6, which reads: "All officers appointed to permanent posts in the Colonial Service between the break of war and a post-war date, to be fixed by the Government of State, will be regarded as having entered the service in single group. The seniority of such officers as between themselves in a given Colony will be reckoned by age."

The Federation of Malaya, on account of local issues, are unable to accept this formula and will only accept that seniority should date from the date of appointment to Colonial Service. As the only I.M.S. officers appointed to Malaya so far have been on contract terms, the question of seniority does not arise in their case.

AUSTRALASIAN MEDICAL CONGRESS (B.M.A.),
6th SESSION, AUGUST, 1948

The Federal Council has decided to resume holding sessions of the Australasian Medical Congress (B.M.A.) after a lapse of nine years. The next session will be held in Perth, Western Australia, from August 15 to 21, 1948, and the Association has been invited to appoint representatives. Members of the Association who propose to attend the Congress and who would be willing to act as representatives of the parent body, if invited to do so, are asked to communicate with the Secretary of the Association, B.M.A. House, Tavistock Square, London, W.C.1.

Correspondence

Questions to Minister: Correction

SIR,—In the interests of accuracy I write to correct an error which has crept into the report of the Special Representative Meeting (*Supplement*, June 5, p. 147). You quote the Chairman of Council as saying (p. 147): "The Council devised a series of questions which were put to the Minister and his answers were obtained." In fairness to the Council it ought to be made quite clear that it was the N.H.S. Executive Committee which devised the questions. The Council as a whole did not have access to either the questions or the answers until both were read out by the Secretary at its meeting during the afternoon of April 14, when the decision to hold the second plebiscite was promulgated.—I am, etc.,

Harrow, Middlesex.

J. B. WRATHALL ROWE.

Association Notices

WEMBLEY DIVISION

Notice is hereby given by the Council of the Association to all concerned of the formation of a new Wembley Division comprising the area of the Borough of Wembley. The new Division will form part of the Metropolitan Counties Branch.

CHARLES HILL,
Secretary.

LONDON SATURDAY JUNE 26 1948

MODERN THERAPY OF BENIGN TERTIAN MALARIA

BY

J. F. MONK, B.M., B.Ch.

Not the least beneficial result of prosecuting a war widespread throughout highly malarious regions after being deprived of our main sources of quinine has been the impetus given to the search for the ideal antimalarial drug. A vast army maintained in the field is an excellent source of clinical material to the research worker, and has been responsible for the determination of the properties of many drugs which would have taken twice or thrice as many years of peace to elucidate partially.

At the onset of the recent war, mepacrine had the reputation of being a poor prophylactic agent and one which could not be taken in adequate dosage by the majority of persons owing to its toxic properties. This reputation had been built up during 10 years of investigation since its synthesis in 1930. Within about 12 months of its adoption in place of quinine it was established as being slightly toxic in a very small proportion of cases treated and to be a very satisfactory suppressive agent.

At the same time it was recognized that mepacrine had many disadvantages from both the prophylactic and the therapeutic aspects. Urgent and enthusiastic research then developed with the object of discovering a drug having all the properties of an ideal antimalarial substance—namely, one which, given in infrequent and non-toxic but regular doses, would prevent the establishment of any form of plasmodial infection, and which also, when given in therapeutic doses over a short period, would produce both rapid clinical and radical cure without any unpleasant side-effects. Such an ideal has not yet been achieved, but many new and invaluable drugs have been synthesized and explored, and these have largely altered the outlook on the treatment of malaria.

In particular, the brilliant researches of Cird, Davey, and Rose¹ resulted in the synthesis of paludrine, a new antimalarial drug with exceptional properties, particularly in its action on the pre-erythrocytic stages of the malaria parasite. In America a vast co-ordinated programme of research was undertaken² and over 14,000 synthetic drugs have been exhaustively tested for their antimalarial properties. Of the large number which were shown to have both suppressive and curative actions, two have emerged as being of great value, and have been given the non-proprietary names of chloroquine³ and pentaquin.⁴

The object of this paper is to review the stage at which the treatment of benign tertian (B.T.) malaria has arrived. Malignant tertian (subtertian) malaria presents difficulty only in its diagnosis, since the establishment of *Plasmodium falciparum* in the human host can be almost entirely prevented by regular dosage with almost any antimalarial drug. Its eradication is likewise easily procured if diagnosis is made early enough and there is no cerebral involvement. First relapses are very unusual after any adequate treatment, and second relapses even less common. The

treatment of benign tertian malaria, on the other hand, is concerned almost entirely with the prevention of relapses.

The following drugs will be considered: quinine (Q), a complex quinidine compound; mepacrine (M), an acridine dye; paludrine (X), a biguanide derivative; chloroquine (C), a 4-aminoquinoline derivative; pamaquin (P), an 8-aminoquinoline compound; pentaquin (SN), an 8-aminoquinoline derivative. Table I lists a series of results from the administration of a wide range of treatments for the cure of B.T. malaria.

It is emphasized that the expected relapse rates following various forms of treatment quoted elsewhere in this paper are no more than approximate estimations. Under certain circumstances the actual relapse rate may differ widely from the expected relapse rate. Saper⁵ has emphasized that in interpreting the often conflicting results even of similar therapeutic regimes the percentages of medical cure obtained depend on three factors: (1) the percentage efficacy of the drugs used; (2) the percentage efficacy of the immune response; and (3) the inherent characteristics of the causative species or strain.

In endeavouring to estimate the value of the first factor, the second and third must always be taken into account. The second factor is usually difficult to assess, but the third is based on information that is more readily available. It is the difference in geographical strains which is most likely to be responsible for apparent discrepancies in the success of various therapeutic regimes. The Chesson strain, for example, used by American research workers⁶ originated in the South-west Pacific and is notorious for producing rapid and often-occurring relapses after antimalarial therapy. Other strains commonly met with produce relapses less frequently and at longer intervals. It is therefore also important to take into account the duration of the follow-up period when comparing relapse rates.

Treatment Involving Use of Only One Drug

Quinine

The relapse rate following treatment with quinine alone in an adequate regime averages well over 50%. A regime is considered inadequate if the daily dosage totals less than 30 gr. (2 g.) and is given for less than 10 days. In a series of cases (Q) treated by Most *et al.*¹³ the relapse rate after a 14-days course was nearly 90%. This is probably exceptionally high. When, however, as so often happens, treatment is self-administered and lasts only three to four days the relapse rate is likely to be over 90%.

When the object of treatment is the production of radical cure unaided quinine therapy is of very little value. Considering that there are more valuable methods of treatment which can produce radical cure in 8 or 9 out of every 10 cases treated, it is questionable whether there is any profit in persevering with treatment for the whole of 10 days

TABLE I.—Comparative Relapse Rates

Course	Reference	Geographical Strain	Dosage	Days of Treatment	Days of Follow-up	Cases Treated	Cases Relapsed	Rel. Rate

* Artificially sporozoite-induced malaria.

in the absence of symptoms when there is at best only an even chance of escaping a relapse during the next few weeks. The disuse of quinine alone for the treatment of *P. vivax* infections should be recommended.

Mepacrine

The relapse rate following treatment with mepacrine alone is rarely lower than 25%. In a series (M3a) reported by Most *et al.*¹³ the figure given is 84%. This is unusually high. It is probably true to say that on the average two out of every five cases treated relapse at some subsequent date.

The actual amount of drug administered appears to be relatively unimportant in the production of radical cure, although rapid clinical cure is more easily produced by a boosting dose at the beginning of therapy. In two parallel and strictly comparable series of cases (M2 and M3b) treated in Rome by Innes *et al.*⁵ and followed up six months later¹⁰ a larger total dosage of mepacrine produced a significantly higher relapse rate than a smaller dosage regime given over an equal period of time. An increase in the total duration of treatment also appears to have little significant effect in improving the success rate. (Compare Courses M1b and M2.)

The popularity and value of mepacrine in the treatment of *vivax* malaria from a military point of view was due to the fact that it can be given in a short course of only seven days' duration without prejudicing the final result; and to the fact that, since it is only slowly excreted, relapses consequently rarely occur within two to three months of discontinuing treatment. At the same time there is no interference with prophylactic mepacrine. With other forms of therapy, such as quinine and pamaquin given concurrently, although the success rate is much higher, the relapses that do occur relapse often within two to three weeks of discharge from hospital, and in this respect are

less welcome from a military point of view than those which relapse after two to three months.

The toxic effects of mepacrine when given in normal therapeutic dosage are negligible. Some cases, however, show an idiosyncrasy and present quite dramatic reactions to small amounts of this drug. Such reactions (mental disturbances, acute abdominal pain, etc.) should always be kept in mind when a course of therapy is started.

Paludrine

The relapse rate following treatment with paludrine alone is rarely less than 35%. In a small series of patients (X1b) from India and the Far East treated at Woolwich¹⁰ the relapse rate was 66.6%. On the average probably at least two out of every five patients treated relapse after five to six weeks or longer. The therapeutic value of paludrine alone is probably no greater than that of mepacrine.

Paludrine is remarkable in that, given in a total amount as small as 50 mg., it is capable of producing clinical cure of an overt attack of B.T. malaria. Experiments are therefore being conducted at Liverpool⁹ in order to test the curative value of paludrine given in a once-weekly dosage over a period of six or more months.

The outstanding value of paludrine is as a prophylactic or as a curative when given concurrently with pamaquin. The importance of the latter regime will be discussed later. As a prophylactic a dose as small as 100 mg. once or twice weekly is adequate to produce complete suppression of all manifestations of malaria. It does not, however, prevent the establishment of *vivax* infection, although it has been shown to inhibit to some extent the exo-erythrocytic forms which exist in the interval between the disappearance of the sporozoites from the blood and the demonstration of parasites 8 to 10 days later in the peripheral circulation.⁴ The only other drug so far demonstrated to possess this property is pamaquin.

Paludrine produces negligible toxic reactions unless given in amounts approximately twenty times the therapeutic dose. It has the advantage over mepacrine that it does not discolour the skin.

Chloroquine

This was synthesized in 1944 in the United States and has had extensive trials in America, particularly as a prophylactic agent for the suppression of malaria. It is highly active as a schizonticide in all types of plasmodial infection, but it "does not prevent relapses in vivax malaria even when administered in doses many times those required to terminate an acute attack." Rapid clinical cure is produced with only small amounts of the drug and in very short courses, as in the case of paludrine. Relapses, however, are very frequent, and occur several weeks after discontinuing treatment, since, like mepacrine, chloroquine is only slowly degraded in the body.

Chloroquine is an excellent prophylactic, considerably superior to mepacrine and qualitatively comparable to paludrine. Given in doses of 300 mg. once or twice weekly it has been shown to produce effective suppression of all forms of malaria. It does not, however, prevent the establishment of vivax infection, but merely prevents the appearance of symptoms, and does not appear to have any action upon the pre-erythrocytic forms of the parasites. On discontinuing treatment, as with mepacrine and paludrine, an overt attack of B.T. malaria will develop several weeks later. As with paludrine, there is a wide margin between the therapeutic and the toxic dose, and no discoloration of the skin is produced with prolonged dosage.

Toxic reactions following normal therapeutic or prophylactic dosage are negligible.

Pamaquin

Although pamaquin has the reputation of being of little value as a schizonticide, it is capable of producing radical cure in an easily tolerated dosage. In a small series (Pb) treated at Woolwich¹ with 11 mg. t.d.s. for 10 days the relapse rate proved to be only 27.6%, comparing very favourably with a series of similar cases treated with paludrine alone. Against artificially induced infection with the Chesson strain (Pa) pamaquin proved ineffective in preventing relapses in all five cases treated.¹

Pamaquin has acquired an undesired reputation as a most dangerous drug. It is true that there is a very small margin between a therapeutically effective dose and one that is severely toxic. The toxic symptoms, too, are somewhat dramatic. Unless, however, pentaquin is shown to produce even more encouraging results than those expected of it, pamaquin will continue to be of the greatest importance in the treatment of vivax malaria. Its value, which will be discussed later, lies in the fact that, given concurrently with other drug therapy, it almost invariably lowers the relapse rate. This can be clearly seen from Table II and the Chart.

TABLE II.—The Value of Pamaquin in Antimalarial Therapy

Course	Dosage Regime	Cases Treated	Relapses	Relapse Rate % of All Cases Treated	Relapse Rate % Cases Followed Up for 6 Months
QNP	Quinine 90 gr. in 3 days. Mepacrine 1.5 g. in 5 days Pamaquin 90 mg. in 3 days	29	5	17.2	19.2
MP	Mepacrine 2.4 g. in 7 days Pamaquin 90 mg. in 3 days	29	3	10.3	12.5
QPD	Quinine 10 gr. + pamaquin 10 mg. t.d.s. for 10 days	94	11	11.7	14.3
M1b	Mepacrine 4.6 g. in 12 days	86	23	26.7	35.0
M2	Mepacrine 3.1 g. in 7 days	31	11	35.5	44.0
M3b	Mepacrine 2.4 g. in 7 days	29	8	27.6	23.6
QM	Quinine 90 gr. in 3 days Mepacrine 2.5 g. in 5 days	21	5	23.8	26.3

Chart showing effect of pamaquin on relapse rates.

The toxicity of pamaquin will be discussed under quinine-pamaquin therapy.

Pentaquin

The relapse rate following treatment with pentaquin alone is not yet fully established. In a small series (SNb) treated at Woolwich¹ the relapse rate was as low as 12.5%. In a series of five cases (SNa) artificially infected with the Chesson strain treated at Stateville¹ three relapsed. In a large series of cases pentaquin would probably be found to give a relapse rate of not less than 25%. Pentaquin, which is very closely related to pamaquin, was synthesized in the United States in 1945. It is a very active schizonticide which produces rapid clinical cure. The recommended dosage should not exceed 60 mg. daily for 10 to 14 days.

Toxic reactions are the same as those met with in pamaquin therapy. "At the therapeutic dose, the toxicity of pentaquin is qualitatively the same and quantitatively approximately one-half to three-fourths that of pamaquin in adult persons." In the Woolwich series of 25 cases a daily dosage of 60 mg. produced toxic reactions in over 50% of those treated.

Pentaquin, as will be shown later, is of greatest value when given in conjunction with quinine.

Treatment Combining One or More Drugs

Quinine and Pamaquin

The specific action of pamaquin in reducing the relapse rate following quinine therapy was pointed out nearly 20 years ago.¹ Since that time quinine 10 gr. (0.65 g) given concurrently with pamaquin 10 mg. 8-hourly for 10 to 14 days has come to be used as the standard control course for the evaluation of other forms of treatment. Until the introduction of treatment combining paludrine with pamaquin, and pentaquin with quinine, quinine-pamaquin was the most effective of all forms of therapy for the radical cure of vivax infections. It is rapid in its clinical action, rarely produces symptoms of toxicity, may be given to ambulant patients on light work, and on the average produces radical cure in eight or nine out of every ten patients treated (Table I, Courses QPa-g).

The minor disadvantage that quinine is preferably administered in liquid form and has an unpleasant taste may lead to its replacement by paludrine-pamaquin treatment, since the latter has been shown to be probably as successful in producing radical cure. The final judgment on quinine-pentaquin therapy will have to await the results of wider field trials.

It is usually recommended that pamaquin administration should take place under medical supervision in hospital. Although an ideal, such precautions are unnecessary in a large majority of cases, particularly those treated with quinine and pamaquin, provided that the daily dosage of pamaquin never exceeds 30 mg. In a series (QPa) of 168 cases occurring in British troops treated at Woolwich¹ only 18 showed toxic symptoms. All except one of these 18

cases required no modification of their dosage and continued to be treated ambulant for the last seven days of their 10-day course without any adverse effects. The exception developed malaria while convalescent from lobar pneumonia, and the appearance of rather more severe toxic signs in a debilitated patient made it advisable to discontinue therapy.

Cyanosis and gastric symptoms are the common manifestations, but do not in themselves indicate discontinuance of treatment, only requiring that an increase in their severity or the development of additional symptoms should be at once reported and investigated.

The premonitory general malaise and anorexia of the patient is usually a good indication of the degree of toxicity prevailing, and such symptoms require to be pronounced before discontinuation of treatment need be considered. Signs of intravascular haemolysis are a clear indication for immediate withdrawal of the drug; they occur more often in the dark-skinned races.

Paludrine and Pamaquin

Treatment with paludrine alone has been shown to give a relapse rate of 35-40%. When pamaquin is added to the regime the success rate is at once improved. Pamaquin exerts a similar specific action in lowering the relapse rate to that found when it is administered concurrently with quinine. In the two series (PX1 and PX2) shown in Table I the results were almost identical with those found in the control series treated with quinine-pamaquin (QPa and QPf respectively).

It will be noted that the total amount of paludrine in course PX1 is two and a half times that given in course PX2, and that despite this larger dosage, when compared with the control, the success rate is no higher. This is the more important since with the higher dosage of paludrine the incidence of toxic reactions was considerable, approximately 40% of cases showing cyanosis or gastric symptoms. There was also a marked anorexia and malaise in the great majority of patients which compared unfavourably with the state of well-being of the control series treated with quinine-pamaquin.¹² In the other series, in which the paludrine dosage was only 300 mg. daily, the toxic side-effects were negligible.⁴ This difference in toxicity of the two courses is due to the fact that, like mepacrine, paludrine is a stronger base than pamaquin and displaces it from the tissues. The toxic reactions therefore are related not to paludrine but to a high plasma pamaquin level.

The optimum eight-hourly dose of paludrine when given concurrently with 10-mg. doses of pamaquin is probably 100 mg. or less. Such a course of treatment is likely to prove at least as successful as quinine-pamaquin therapy.

Combinations of Quinine, Mepacrine, and Pamaquin

Quinine, mepacrine, and pamaquin have been given in various combinations for the treatment of B.T. malaria. A commonly used regime consisted of quinine 10 gr. t.d.s. for three days, followed by 1.5 g. of mepacrine, given in five days, followed by 10 mg. of pamaquin eight-hourly for three days. Good results, with moderately low relapse rates, were obtained with this course, but generally speaking it is less successful than quinine-pamaquin therapy.

Innes *et al.*⁹ treated several series of cases at Rome with different combinations of these drugs. These were followed up six or more months later,¹⁰ with the results shown in Table II.

The significance of these figures is less in the actual relapse rates obtained than in the comparative results (see Chart). It is clearly shown that the three courses which contained pamaquin had a higher rate of success than the

other forms of treatment. The relapse rate following therapeutic regimes containing pamaquin is 12.5%, whereas that following the four other modes of treatment which exclude pamaquin is 28.2%.

The bad reputation suffered by pamaquin should not be allowed to nullify this important conclusion. Until pamaquin is convincingly shown to be the drug of choice pamaquin should continue to be given as an essential part of any attempt to eradicate *vivax* infection, whatever course of therapy is preferred. It must be remembered that pamaquin should not be given concurrently with mepacrine, for the latter causes the plasma pamaquin level to rise considerably, resulting in serious toxic reactions. Pamaquin is undoubtedly best administered concurrently with quinine or paludrine.

Quinine and Pentaquin

Preliminary indications from America regarding this latest form of therapy indicate that it is likely to be more successful than any other treatment yet devised. Pentaquin is still under trial and not yet generally available, so that final judgment will have to be suspended until a large complete series of cases of naturally occurring *vivax* malaria has been treated and adequately followed up against standard controls.

It was probable that pentaquin, being an 8-aminoquinoline derivative closely related to pamaquin, would have a specific action in reducing the relapse rate when administered with quinine. This indeed has been the case, for, although the results from Stateville¹ are as yet incomplete, interim reports show that against the Chesson strain of *P. vivax* (QSNa) the expected relapse rate is far lower than with any other mode of treatment suggested for this severe type of malaria.

In a series of 26 cases of naturally occurring B.T. malaria (QSNb) treated at Woolwich¹¹ three cases are detailed as relapsing, but none in fact had proved infections. Two patients treated themselves with mepacrine at the onset of symptoms, which were as likely to be due to coryza as to malaria; while the third did report having symptoms suggestive of a rigor. A relapse rate nearer 5% would probably be a more accurate estimate for this series of cases.

With the recommended dosage of 60 mg. daily very few, and only mild, toxic symptoms have been reported from America.¹ These consisted of cyanosis of a mild degree and occasional abdominal pain. In the Woolwich series these symptoms and signs were encountered in over 50% of the cases treated. One patient also developed pyrexia and pain in the hepatic area, and treatment was discontinued. The general malaise and anorexia of the great majority was in marked contrast to the good health and appetite of those treated with quinine-pamaquin.

Intermittent Therapy with Quinine-Pamaquin and Mepacrine

Innes *et al.*⁵ treated a series of cases at Rome on intermittent regimes of quinine-pamaquin and mepacrine. The follow-up of these cases six months or more later showed remarkable results.¹⁰ The courses used were as follows:

Mepacrine.—An initial course of 2.5 g. in five days followed by two courses of 3 g. each given in six days, with "rest" periods of seven days between all courses.

Quinine-Pamaquin.—An initial course of quinine 10 g. plus pamaquin 10 mg. given eight-hourly for seven days, followed by two similar courses of five days each with "rest" periods of seven days between all courses.

The patients chosen were those who had experienced six or more relapses in the previous six to nine months. At the time of treatment all patients had recently concluded a

course of therapy and were consequently symptomless and parasite free. The results are summarized in Table III.

TABLE III.—Results of Intermittent Therapy

Course	Cases Treated	Cases Followed Up	Relapse Rate	Relapse Rate of Those Succeeded Followed Up for 6 Months	Relapse Rate of All Cases Treated
Intermittent mepacrine	42	66	12	42.9%	28.6%
Intermittent quinine-pamaquin	45	62	0	Nil	Nil

It was regrettable that more cases could not be followed up, but owing to the exigencies of war the majority of the Dominion troops could not be traced. Nevertheless the result of the intermittent quinine-pamaquin treatment is significant and in remarkable contrast to the results obtained in any other series of cases treated in the Mediterranean area.

The rationale for such treatment was based on the discovery by Innes *et al.* that during treatment with quinine or mepacrine a drug-inhibited stage of development of the plasmodium occurred corresponding to the pre-schizont stage, and persisted for at least 12 to 24 hours in the peripheral circulation after other parasites had undergone schizogony. A tentative hypothesis suggests that if relapses of malaria can at all be ascribed to these drug-inhibited or retarded development forms, they may possibly persist in the host until the plasma drug level has fallen low enough for their redevelopment to take place. Such relapses would occur during the "rest" periods of the intermittent therapy. The majority of the organisms would be destroyed by the second course of treatment and the remainder by the third course. For the success of such a regime it would be necessary to use a drug which is rapidly excreted from the body. Mepacrine is unsuccessful because it is slowly excreted and the "rest" periods are not long enough to allow recrudescence of the drug-inhibited forms.

It would be of great interest to pursue such treatment in a large series of cases. The course has the disadvantage that it is lengthy, but it is also harmless and may be given without risk to patients on a full day's light work, provided they consult their medical adviser at the first suggestion of toxic symptoms. Such treatment would probably be preferable to 10-day courses of high-dose or paludrine possibly more profitable than the 2-monthly. The latter taken over a period of six months is successful in a climate treatment, although likely to produce somewhat too prolonged to be adhered to by the majority of patients.

Summary and Conclusions

The ideal drug for the prevention and radical cure of benign tertian malaria has yet to be discovered. The use of quinine is recommended. The disuse of unaided quinine treatment is recommended. Suppressive and curative treatment with mepacrine is likely to be superseded by more recently discovered antimalarial drugs.

Paludrine and chloroquine are probably equally effective in producing complete suppression of overt attacks of malaria in once-weekly dosage. Neither is able to prevent the establishment of *P. vivax* in the human host even by daily dosage, but paludrine has some inhibitive effect on the pre-erythrocytic forms. Neither drug given alone is as successful as other forms of therapy in producing a permanent cure.

Pamaquin is a drug which deserves greater recognition as a safe medium for the elimination of *P. vivax* infections. Given as an adjuvant in any course of antimalarial therapy it is of the greatest value in reducing the relapse rate. The toxicity of pamaquin is shown to be less formidable than is generally accepted.

No treatment so far administered to a large series of cases of naturally occurring B.T. malaria is more successful than quinine given concurrently with pamaquin. Paludrine given concurrently with pamaquin is equally successful.

Pentaquin given concurrently with quinine is likely to prove more successful in producing a lower relapse rate than any other therapeutic regime. The toxicity of pentaquin is approximately three-quarters that of pamaquin.

A 31-days intermittent course of quinine and pamaquin proved successful in the complete eradication of *P. vivax* infections in all patients followed up in a series of 45 cases. It is suggested that such a course is worth extended trials among chronic relapsing cases in a non-malarious area.

I wish to acknowledge permission from the Consulting Physician to the War Office to quote from the 1945-6 report of No. 2 Malaria Research Team, R.A.M.C. The work done by his team was the instigation of the Medical Research Council. I wish to thank Dr. Alf S. Alving, of the University of Chicago, for permission to quote figures obtained from his work at Sisseton, and Dr. F. Hawking of the Medical Research Council, for his hospitality in reading the reports to the National Institute of Health, America.

DEMONSTRATION OF A PERSISTING EXO-ERYTHROCYTIC CYCLE IN PLASMODIUM CYNOMOLGI AND ITS BEARING ON THE PRODUCTION OF RELAPSES

BY

H. E. SHORTT, C.I.E., M.D., D.Sc., D.T.M.&H.
 Director, Department of Parasitology,
 London School of Hygiene and Tropical Medicine

AND

P. C. C. GARNHAM, M.D., D.P.H.
 Reader in Medical Parasitology, University of London

From the earliest days of the modern study of malaria the phenomenon of relapses in this disease has been invested with a mystery which has been responsible for various hypothetical solutions made in an attempt to explain the known facts.

The first of these facts is that periods of patent infection accompanied by the demonstrable presence of parasites in the peripheral blood are often succeeded by more or less prolonged periods when no such parasitaemia can be demonstrated. This condition is described as latent malaria, and it may supervene in the natural course of the disease or may be produced artificially by the use of anti-malarial therapy which destroys the erythrocytic infection. Another fact is that such relapses are often precipitated by

any happening which causes a temporary lowering of the host's resistance, and the problem here is the source of the parasites producing the relapse. A third fact is that the various species of malaria parasites vary in their tendency to relapse and in the period of years during which relapses may recur. A final fact relates to artificially produced infections. Those which are produced as the result of inoculation of blood show no tendency to relapse after anti-malarial treatment, while those induced by sporozoite inoculations, either artificially or by mosquito bite, tend to produce relapses after the cessation of treatment.

The extent to which these facts are explained by the finding that is the subject of this communication is dealt with in the discussion.

Up to the present time three commonly adduced explanations of relapses have held the field, but, in the absence of accurate knowledge of the life-cycle of malaria parasites, none could claim greater weight than a mere guess. These theories are: (a) The continued existence of a low-grade erythrocytic infection kept in abeyance by the host's immune mechanism but flaring up on any impairment of the latter; (b) the theory of the parthenogenetic development of the female gametocyte (Grassi, 1900; Schaudinn, 1902); (c) the existence of a cryptic stage in the internal organs capable of producing an erythrocytic invasion on any lowering of the host's resistance. The third of these theories gained added weight with the discovery of the exo-erythrocytic cycle in bird malaria, where these forms play an important, if not the essential, part in the causation of relapses.

The possibility that the hypothetical exo-erythrocytic cycle in mammalian malaria played a similar part in the production of relapses has been put forward at various times by many workers, and the names given in brackets are only a representative selection from workers who have made such a suggestion, after the first establishment of a definite exo-erythrocytic cycle in bird malaria by James and Tate in 1937. (James and Tate, 1937; Shortt, Menon, and Iyer, 1940; Fairley, 1945; Huff, 1947; Cooper, Ruhc, and Coatney (personal communication to Huff), 1947; Shortt and Garnham, 1948.)

The discovery recorded in this paper of the continued existence in monkey malaria of the exo-erythrocytic cycle after establishment of the blood infection would appear to constitute the strongest proof that this form of the parasite is the aetiological agent concerned in the production of relapses. When we (Shortt and Garnham, 1948) published a detailed description of the pre-erythrocytic cycle in *P. cynomolgi* and *P. vivax* we suggested that if this cycle was found to persist after establishment of the blood infection it might play an essential part in the maintenance of the infection over long periods and in the production of relapses, so that the present work is the logical sequence to the experiment establishing the pre-erythrocytic cycle in mammalian malaria.

To investigate the theory of the persistence of the exo-erythrocytic cycle and its relation to relapses, examination of infected monkeys a considerable time after the establishment of sporozoite-induced infections seemed to offer the most direct approach to the problem. For this purpose we selected a monkey (*Macaca mulatta*) originally infected by sporozoites, in which the infection had reached a latent stage. This stage, with apparent absence of parasites in the peripheral blood, had lasted for over a month, and from our experience it was considered probable that a relapse would soon occur.

If we were correct in this assumption and if the hypothetical exo-erythrocytic forms, probably in the liver, were to be the source of parasites for the relapse, it would follow that examination of the liver would reveal these forms if

in sufficient numbers to make this a practical proposition. This aggregation of "ifs" did not allow us to draw an easy or rapid conclusion to the investigation, but events turned out, the monkey chosen proved to be at the earliest stage of an imminent relapse and we were able to demonstrate the presence of an exo-erythrocytic stage. This finding is considered important enough to justify setting forth in detail the history of the monkey concerned. This is given below.

Monkey 37 (Macaca mulatta). Weight 3 lb. Feb. 18, 1948: Fed on by 680 *Anopheles maculipennis* infected with *P. cynomolgi*. The mosquitoes were then ground up, in 0.5 ml. serum-saline, and inoculated into the same monkey intratoneally and intramuscularly. Sporozoites were microscopically demonstrable in the 10-ml. volume of the suspension. Mosquitoes of this batch were fed, as a control, on Monkey 38, which developed malaria on March 2. On dissection of six of these mosquitoes five contained sporozoites in the salivary glands, showing that a very high proportion of the batch must have been infective. Feb. 21: A piece of liver removed by open operation. Feb. 23: A second similar operation. Feb. 26: A third similar operation. March 1: Blood contained rings and maturing schizonts. March 10: Numerous mature gametocytes present. April 1: Blood negative. April 7: Scanty infection of blood. April 24: Condition of blood similar. May 5: Blood negative. May 22: Blood negative. May 26: Blood negative. June 1: Blood negative. Piece of liver removed by open operation. June 2: Considerable numbers of very early ring forms (23 in 100 fields of 1/12 oil immersion lens). June 4: Scanty mature schizonts.

The piece of liver removed on June 1 was placed in Carnoy's fixative and sections were prepared. These showed the presence of exo-erythrocytic forms of *P. cynomolgi*.

Description

The description given applies to the two exo-erythrocytic parasites encountered. The first was situated in a parenchyma cell of the liver and extended over four serial sections cut at 4 μ in thickness. This would give the parasite a diameter of 16 μ , which was confirmed by actual measurement of the longest diameter. The stain in use was the modified Giemsa previously employed by us for pre-erythrocytic stages of *P. cynomolgi* in sections of liver.

The parasite was an almost spherical schizont lying in a parenchyma cell, the cytoplasm of which was separated from the schizont by a clear area either due to shrinkage or to some cytolytic effect. In one part of the periphery of the infected liver cell was the nucleus, itself somewhat flattened but not obviously degenerate.

The parasite had a pastel-blue-staining cytoplasm, markedly and coarsely granular and with a single sharply differentiated spherical blue staining mass, the origin and explanation of which is obscure. In this cytoplasm were distributed irregularly shaped masses of chromatin staining a magenta colour and numbering about 130 when counted over the four sections in which the parasite appeared. This schizont was similar in appearance to those described by us as occurring in the pre-erythrocytic development of *P. cynomolgi*, and in size and general morphology was comparable to a parasite between the fifth and sixth days of pre-erythrocytic development. The parasite appeared to be bounded by a wavy line which might indicate a containing membrane.

It does not, of course, follow that the size of this exo-erythrocytic form would necessarily imply that it was of the same developmental age as a pre-erythrocytic parasite of the same size, but this is probably a justifiable conclusion in the absence of any contrary evidence.

The second parasite encountered, almost spherical in shape, was in an advanced stage of development, comparable to the eighth-day stage of the pre-erythrocytic cycle and measured 30 μ in the longest diameter. The blue

toplast showed commencing segregation to form merozoites, the chromatin particles of which numbered over 500. The cytoplasm exhibited two small vacuoles and several very densely stained blue masses which we interpret as dual bodies. The outline of the parasite was wavy as the smaller form.

After the exo-erythrocytic cycle has been in progress for some time synchronism among the parasites is lost and o-erythrocytic forms in various stages of development may be found, presumably from their first entry into the

In 1948 we propounded an almost identical view in saying: "If certain of the merozoites resulting from exo-erythrocytic schizogony enter fresh liver cells to maintain the local liver cycle, the destruction of the blood infection, either by specific immune response or by chemotherapeutic agents, would possibly leave intact the exo-erythrocytic cycle, which, under a suitable stimulus, could renew the blood infection."

It is true that the continuance of an exo-erythrocytic cycle is not clear scientific proof that this is the source of

Two exo-erythrocytic schizonts of *Plasmodium cynomolgi* in sections of liver, the probable cause of relapses in simian malaria. Photographed on the same scale, $\times 1700$.

liver cells up to mature schizonts. The relative rarity of these bodies is indicated by the fact that 412 sections were examined in finding two schizonts.

Discussion

The finding of exo-erythrocytic schizonts of *P. cynomolgi* in the liver of a monkey nearly three and a half months after the production of a sporozoite-induced infection is unequivocal evidence of the persistence of the exo-erythrocytic cycle after establishment of the blood infection. That this finding is the fulfilment of intelligent anticipation by various workers will be evident from the following quotations, which are only three chosen from many others.

Thus Fairley (1945) writes: "The reappearance of erythrocytic forms in *P. vivax* after the blood has been completely cleared of parasites, no less than the tendency of benign tertian infections to relapse repeatedly, despite prolonged antimalarial treatment, suggests the persistence of a tissue stage (exo-erythrocytic form) which, from time to time, throws off asexual parasites into the circulation for invasion of the erythrocytes."

Huff (1947) states: "There is a suggestion, though no clear proof, in these statements that any hypothetical phanerozoic stages in human malaria may arise principally, if not wholly, from the, as yet, hypothetical pre-erythrocytic stages."

clinical relapses, but there are various facts which seem to make that a reasonable conclusion. Thus in the course of an infection there are long periods when the presence of parasites in the circulation cannot be demonstrated even by inoculation of blood into susceptible hosts. Again, in the case of sporozoite-induced infections, antimalarial treatment can suppress the erythrocytic cycle before a clinical attack is manifested or can apparently effectively sterilize the blood of the erythrocytic cycle when this is present. Yet after a longer or shorter interval relapses will occur, and these presumably are caused by merozoites originating in the exo-erythrocytic schizonts in the liver.

Lastly, work on bird malaria and recent work on the exo-erythrocytic cycle in man (Shortt and Garnham, 1948) have shown that immunity against the erythrocytic parasite is not active against the exo-erythrocytic parasite. This is possibly because the latter in their intracellular habitat in the parenchyma cells of the liver are protected from the host's immune mechanism and become susceptible only when the merozoites are released. In these circumstances those merozoites which regain other liver cells are similarly protected and the liver cycle can go on for an indefinite period independently of the blood infection.

In the case of the monkey which was the subject of this experiment the fact that the blood was negative on the day of the operation and became positive on the day after would indicate that we were correct in expecting an early

relapse and, in fact, that the relapse was imminent on the day of the operation. The finding of a contemporaneous exo-erythrocytic cycle would supply a reasonable explanation of the source of the parasites producing the relapse if the interpretation of our findings given below is accepted.

Although it involves some repetition, we think it would be useful to give, in a few words, our interpretation of the findings obtained in our recent work on the exo-erythrocytic cycle in mammalian malaria.

The inoculation of sporozoites by the infected mosquito is followed by a pre-erythrocytic development in the parenchyma cells of the liver, with the ultimate production of merozoites. Many of these enter the erythrocytes to produce a parasitaemia and a clinical attack of malaria. Other merozoites enter normal liver cells and repeat the process of exo-erythrocytic schizogony. This latter process repeats itself indefinitely, irrespective of whether the erythrocytic cycle is present or is in abeyance as the result of antimalarial treatment or a naturally acquired active immunity. This active immunity is operative only against the erythrocytic parasites and destroys those merozoites liberated by the exo-erythrocytic schizonts which are destined to enter red cells. Those which enter liver cells to maintain the exo-erythrocytic cycle are protected from this immunity by their intracellular position outside the circulating blood.

If for any reason, the active immunity of the host is removed it no longer operates against the merozoites destined to start the erythrocytic cycle, and these enter the blood cells and initiate a clinical relapse.

The marked similarities both in erythrocytic and in pre-erythrocytic stages between *P. cynomolgi* and *P. vivax* make it reasonable to suppose that the course of events here described in the case of the former parasite will be applicable to the latter.

Until recently the fact that exo-erythrocytic development is the rule in the case of avian plasmodia, while it was not demonstrable in the case of mammalian plasmodia, tended to cause some misgiving in placing both groups in the same genus. The discovery, however, of the pre-erythrocytic cycle in simian and human plasmodia appeared to narrow the gap between the two groups, and now that the simultaneous existence of erythrocytic and exo-erythrocytic cycles has been demonstrated in a simian *Plasmodium* there seems still less justification for considering avian and mammalian plasmodia as other than very closely related.

Summary

The finding of exo-erythrocytic schizonts of *Plasmodium cynomolgi* in the liver of a monkey about three and a half months after a sporozoite-induced infection is evidence of the persistence of the exo-erythrocytic cycle after establishment of the blood infection.

Reasons are given for the assumption that this is the cycle responsible for the production of relapses.

As in earlier work in this investigation we wish to record the valuable technical assistance of our staff, Mr. W. Cooper and Mr. E. Blackie and Miss J. Stedman.

BILHARZIAL AFFECTION OF THE URETER

A STUDY OF 110 CONSECUTIVE NECROPSIES SHOWING VESICAL BILHARZIASIS

BY

MICHAEL GELFAND, M.B., M.R.C.P., D.M.R.

Acting Government Pathologist, Southern Rhodesia
Government Medical Service

The ureter is often affected in urinary bilharziasis. The purpose of this article is therefore to report on the various lesions found in the ureter in a series of 110 consecutive necropsies on Africans held at the Salisbury Mortuary, Southern Rhodesia.

The literature would appear to stress the obstructive lesions met with in urinary schistosomiasis. As early as 1919 Fairley drew attention to the tendency of the disease to invade the lower portion of the ureter. He reported that catheterization of such a ureter may reveal a hydronephrosis that has not shown any clinical manifestations. He is one of the early workers to refer to the golf-hole appearance of the ureteric orifice, which he not infrequently found involved even in early cases. In another publication Fairley (1919b) drew attention to the obstruction occurring in a bilharzial ureter, but he also recognized the possibility of a hydronephrosis resulting from obstruction in the bladder-wall itself. In his experimental work on infected monkeys he found that the lumen of the lower third of the ureter may show dilatation and the wall considerable thickening. The dilatation results from obstruction due to thickening from the cellular infiltration of the wall in the neighbourhood of deposited ova.

Aly Bey Ibrahim (1923) published from Egypt an important paper on bilharziasis of the ureter. In it he refers to the very serious complication of stricture of the ureter. He writes: "The disease ends in the formation of fibrous tissue, which replaces the normal coats of the ureter. This leads to contraction and narrowing or even complete obliteration of the lumen of the lower part of the ureter. Secondary to this, the upper part of the ureter and pelvis of the kidney become dilated." Dew (1923), of Egypt, infers that the ureter becomes narrowed because of fibrosis and calcification, contraction ensuing fairly early in the disease. Hydronephrosis as a result is common. Also from Egypt, Hutchison (1928) refers to an ascending pyelitis and hydronephrosis resulting from stasis of the urine, occurring because of obstruction at the lower end of the ureter. Campbell-Begg (1944), writing on schistosomiasis in South Africa, refers to the occurrence of a tight fibrous stricture of the ureter, which is found only in the minority of cases. Kirkaldy-Willis (1946), working in East Africa, mentions the possibility of obstruction in the lower ends of the ureters.

Procedure

Because of the prevalence of urinary bilharziasis in Southern Rhodesia investigation into the incidence of stricture and other possible effects of the disease in the ureter was not difficult. Mashonaland, where the work was done, is a highly endemic focus for both the urinary and the intestinal forms of the disease. Bilharzial disease there is essentially a disease of childhood, acquired by exposure of children in the Native Reserves to infected waters. In fact, in some districts haematuria in a child is regarded almost as a normal phenomenon, and little notice is taken of it. By the time adult life is reached it is safe to assume that the

individual has had the disease for a number of years, and complications in the ureter can be expected.

Adults were therefore chosen for this investigation, as naturally it would take a few years for complications to arise. In all, 110 consecutive cases showing urinary bilharziasis were examined. The vast majority of these were men between 20 and 50. The technique adopted at necropsy was as follows.

After the liver had been removed each kidney was carefully taken out, together with its ureter as far as its lower third in the pelvis. The bladder was then removed below the prostate from its connexion with the urethra and carefully dissected free from the rectum and in women from the uterus. Finally, the lower third of each ureter was dissected out. In other words, the whole bladder, ureter, and kidneys were removed *in toto*. The bladder was then opened with a sharp pair of scissors through the urethral orifice, the incision being continued upwards through the anterior wall, thus exposing to view the fundus (base) and below the trigone.

After the bladder was inspected for signs of schistosomiasis the ureteric orifices were identified and a narrow probe (2 mm. in diameter) was passed up the whole length of the ureters. A stricture was considered to be probably present when a sense of obstruction, tightness or a complete hold-up of the probe was encountered. Later it was found easier and quicker to open the ureter just below its junction with the pelvis and to pass the probe down into the bladder.

With this method a number of apparent strictures were first encountered in some cases as the probe would not pass beyond a certain point. When, however, the ureter was opened along its length from its bladder orifice to the pelvis most of these hold-ups were found to be due to sacculations, dilatations, or any pouch-like distortions in the wall. Only in a few cases was a true reduction in the normal lumen of the ureter demonstrable.

After each ureter was opened its inner surface was carefully inspected for bilharzial patches. In each case the circumference of the ureter was measured at about $1\frac{1}{2}$ in. (3.75 cm.) from its orifice into the bladder. It was found that the normal circumference (as determined in those free of any bilharzial disease) varied from about 5 to 11 mm., with an average of about 8 mm. This site was selected as the disease chiefly affects this portion of the ureter. Other areas were measured, depending on whether disease was found. By this means I was able to determine whether the ureter was narrowed, dilated, or unaltered.

Results

Dilatation was found in the ureter in 25 of the 110 cases. Three others showed stenosis or stricture—that is, reduction of the normal circumference—one case had the lower end of the ureter blocked by a small phosphatic calculus, and in three cases both ureters were dilated because of obstruction reduced at their lower ends by an infiltrating carcinoma of the bladder associated with bilharziasis.

In 16 of the 25 cases the dilatation was unilateral; in 9 of them the dilatation affected the whole length of the ureter, in five it was present in the middle and lower thirds, and in five only the lowest third was dilated. In nine cases the dilatation was unilateral—in two being present throughout the length, in four confined to the middle third, and three confined to the middle and lower thirds of the ureter.

Occasionally those portions of the ureters which dilated by the disease may show one or more narrow constricting fibrous-tissue bands running horizontally, but the lumen at these points was always greater than normal. Two such cases in the above-mentioned series were encountered.

The disease in the ureter can, as a rule, be easily identified, as the patches have a distinctive colour and the mucosa is roughened as if it were sprinkled over with fine sand. The colour of the patches varies from light brown, flowish or greenish brown, to darker brown or a dark-

brown discoloration. They have a roughened feel. In other cases tiny tubercles, like sago grains, are seen, whereas in still fewer cases flattish or even pedunculated "papillomata" are found in addition.

The usual site of the disease was the lower third of the ureter. The dilatation was therefore generally found in this portion, but also not infrequently in the middle or upper third of the ureter. In some cases the dilatation was uniform throughout its length. A very important and interesting observation was that the dilatation was present only where the bilharzial disease was found. Where the ureter looked normal no dilatation could be demonstrated.

If stricture were the cause of dilatation one would naturally expect all portions of the ureter above the obstruction to be dilated, and not, as these cases showed, only at the diseased site. Further, the dilatation often varies from point to point, depending on the local effect of the disease. Thus the ureter becomes corrugated and irregular in its course. In a severe case the ureter may be thrown into folds or assume an S-shaped bend at one or other point. Therefore when a probe is passed upwards it is liable to encounter such a bend or be held up in one of the tiny pockets or corrugations, thus simulating stricture.

To determine the presence of hydronephrosis each kidney was bisected and the size of the pelvis and its calices was noted. So as to exclude urethral obstruction as a cause of hydronephrosis a curved metal sound was passed up the urethra into the bladder. In no case with hydronephrosis was such an obstruction demonstrated. In the series there were eight cases in which hydronephrosis was observed. Four of the 25 cases showing dilatation of the ureter were affected by hydronephrosis (bilateral). One of the three cases of stenosis or stricture showed hydronephrosis on the side of the narrowing (this case also showed dilatation of other parts of the ureter by the disease). All three cases of carcinoma of the bladder were associated with bilateral hydronephrosis due to obstruction of the lower portions of the ureter by the growth.

Of the three cases showing narrowing or stenosis of the lumen of the ureter two did not have any hydronephrosis, but one showed early hydronephrosis on the right side. In its upper two-thirds this ureter was dilated by disease to a circumference of 14 mm. and in its lower third to a similar extent; but in between these two dilated portions was a narrowed portion with a circumference of 8 mm., through which the probe passed easily. The left ureter was dilated by the disease in its lower third. In another of the cases accepted as stricture the probe was held up in the middle third of the left ureter. On opening this ureter a fine fibrous stricture was found. This was the only stricture which held up the probe. In the third case of stricture there was a narrowing at one point to 8 mm. in the middle third of the right ureter, with dilatation above (28 mm.) and below to 20 mm. The probe easily passed up the ureter.

One case of bilateral hydronephrosis was interesting. Although there was bilharzial disease of the bladder and ureters, the latter opened into the apex of the bladder, the orifices being only about $1\frac{1}{2}$ in. (1.25 cm.) apart. The bladder mucosa between the orifices was considerably reticulated and thickened. The ureters were markedly thickened and dilated. The intravesical parts of the ureters were dilated (14 mm. right and 11 mm. left). In this case the hydronephrosis could be explained by the congenital anomaly of the ureteric openings.

The dilatation of the particular part of the ureter affected is usually caused, so far as this study shows, by the disease itself. Owing to infiltration of the wall the affected portion dilates and rarely stenoses, as is commonly thought. As

BILHARZIAL AFFECTION OF THE URETER

BRITISH
MEDICAL JOURNAL

a rule not only is the ureter dilated by the disease but there is well-marked thickening of the coats of the tube by fibrous-tissue formation. This causes the ureter, when removed, to appear somewhat rigid and elongated.

A number of the dilated portions of the ureters affected by bilharziasis were examined histologically. Ova were found not only in the submucosa but also in between the muscle bundles in the muscular layer. The ova are often seen lying together in clumps with a varying amount of fibrous-tissue and inflammatory reaction. Such fibrosis may be slight. This is in striking contrast to the pathological processes in the appendix, where tubercle formation is often observed. It seems to me, therefore, that as a result of the deposition of eggs in the muscle layers the muscle bundles are separated, atrophy ensues, and eventually dilatation sets in. The affected part of the ureter thus widens, elongates, and becomes tortuous.

The ureteric orifice may or may not show changes. In none of the cases in this series was the lumen of the orifice occluded or so narrowed as not to allow the probe to pass with ease. In many of the cases the orifice is widened, producing the golf-hole appearance. In some cases the orifice itself appears smaller than usual, whereas in others it is not easy to find owing to the surrounding disease of the bladder mucosa. In such cases passing the probe downwards in the ureter from above will assist in locating it.

Comments

My results reveal certain interesting points, and if corroborated by others might cause the present-day treatment of bilharzial ureteric disease to be reviewed.

While stricture or stenosis of the ureter is encountered in necropsy, this finding is very much less common than I originally expected. Gelfand (1947) reported a series of 10 consecutive necropsy cases affected by vesical bilharziasis and found only one stricture but many dilated ureters. In one of the three cases showing stenosis in this second series hydronephrosis was present. I do not state that stricture or stenosis is not serious and does not occur in practice or that cases of hydronephrosis due to it are not found. I have seen such cases, but I consider that they are comparatively rare.

My experience goes to show that dilatation of the ureter by the disease is far more common than stenosis or stricture. Such dilatation is usually associated with thickening of the wall of the ureter, which also becomes elongated and tortuous. This effect is usually well demonstrated radiologically. The functions of such a ureter will become impaired, peristalsis will be diminished or lost, and hence urine would not be properly propelled towards the bladder. As a result stasis will follow, and with it some degree of hydronephrosis. This may not be the only explanation of the hydronephrosis in cases showing only dilatation of the ureters. Another possible explanation for some of these cases may be a reflux of urine up an incompetent ureteric orifice during micturition, when the bladder actively contracts. Owing to the dilatation produced by the disease the sphincteric function of the intravesical portion of the ureter is lost or impaired. The hydronephrosis due to such loss of sphincteric function probably explains some of the cases of hydronephrosis seen in prostatic disease (Hughes, 1946).

The ureter when it dilates also lengthens and "unfolds" itself. This "unfolding" may cause the ureter in the paravesical portion affected to assume an S-shaped curve or kink, the simulating stricture. This was seen in one of 25 cases reported with dilatation of the ureter. The ureteric orifice protruded about 2 mm. beyond the

bladder mucosa. The orifice itself was dilated (6 mm.). The tube could be passed neither from below nor from above, and a stricture was held to be responsible for this. However, on opening the ureter the intravesical portion was dilated owing to disease, its circumference being 11 mm. as compared with 8 mm. on the opposite side. The intravesical portion of the ureter had elongated and hence its orifice protruded beyond the bladder mucosa; the rest of it had become "folded," so to speak, upon itself, causing an obstruction.

Recently Dr. N. Barlow, of the Southern Rhodesia Government Medical Service, was able to demonstrate such a reflux in one of my ward cases. The patient, an African male, passed ova of *Schistosoma haematobium* in his urine, and an intravenous pyelogram revealed a well-marked dilatation of the lower end of the right ureter. Dr. Barlow filled the bladder with "uropac" and then inserted the patient to empty his bladder. An x-ray film taken before and after micturition revealed that some of the dye had passed up the ureter from the bladder. In this case there was no evidence of a hydronephrosis on the affected side.

Summary

A series of 110 consecutive necropsies were performed on African adults found to have bilharzial disease of the bladder. In 25 cases the ureters were dilated by the disease. Stenosis or stricture of the ureter was found in three cases. Hydronephrosis was found in three cases showing dilatation of the ureters and in one of the cases affected by stenosis of the ureter.

Possible explanations for the hydronephrosis in the presence of dilated ureters are advanced.

I would like to express my thanks to Dr. R. M. Morris, Medical Director of Southern Rhodesia, for permission to carry out this investigation and to publish my findings. Dr. Graham White rendered invaluable assistance in the mortuary.

Dr. Evang, Chief Medical Officer of the Norwegian Public Health Service, has recently been advocating health passports for all. Often when questioned by his doctor, the patient recalls a tuberculin test but cannot say whether it was positive or negative; his blood pressure was measured recently but he does not know what it was; he has undergone an abdominal operation but is blissfully ignorant of what it revealed. In the autumn of 1946, Dr. Evang set up a committee to study the whole problem of health passports. A year later this committee reported, and the type of health passport it recommends is issued as a supplement to the May 1 issue of *Tidsskrift for Den Norske Lægeforening*. It is a modest 16-page booklet measuring about 6 inches by 4 (15 by 10 cm.). Dr. Evang's committee recommends the issue of this booklet to everyone on leaving school. It is not necessary to provide a similar document for children because their ailments are recorded by the school medical service. The booklet provides a record of diseases in the family and of such children's diseases as whooping-cough. In it are also to be recorded height and weight; blood and urine tests; examinations of the eyes and ears; vaccinations against smallpox, diphtheria, tuberculosis (B.C.G.), and other diseases; doctors' reports and radiological examinations of the lungs; doctors' reports and hospital records with the name and address of the hospital and the nature of the disease for which treatment was given. Disabilities due to disease or injury are also to be entered in this miniature medical biography.

RECENT TRENDS IN TREATMENT OF PROSTATIC OBSTRUCTION*

BY

ARTHUR JACOBS, F.R.F.P.S.

Surgeon, Urological Department, Glasgow Royal Infirmary

The term "prostatic obstruction" implies a wide variety of underlying pathology. It is now generally accepted that the enlargement, whether due to a hyperplasia of pre-existing acinar tissue with an increase of fibrous tissue or to an adenomatous growth, occurs at the expense of the rest of the prostate, which is compressed into a false capsule of fibro-muscular tissue. A benign enlargement arises from the lateral lobes, the median lobe, or, as is most common, from the three lobes in combination, and thus may assume a variety of forms. A normal prostate weighs about 8 g., an obstructing prostate anything up to 200 g. and occasionally more. The so-called median-bar obstruction is not a true prostatic enlargement. It is a thickening of the posterior lip of the vesical outlet, frequently associated with a sclerotic internal sphincter. Another pathological variety is the calculous prostate. The calculi are generally in clusters, the collections varying greatly in size. Sometimes their total dimensions are such as to replace the glandular tissue completely. Finally, there is the malignant prostate, the characteristics of which vary from a small hard gland to that of an immense nodular enlargement.

Symptoms

With these varying types of prostatic pathology in mind, let us consider briefly the symptoms for which they are responsible and which cause the patients to seek advice. These symptoms are as variable as the pathology, but not very much related to it. All types tend to obstruct the outflow of urine. The bladder at first responds to this by a hypertrophy of its musculature, but, sooner or later, as a result of persistence or increase in the degree of obstruction, the hypertrophy is followed by a dilatation, the bladder is unable to empty itself, and a residual urine of variable quantity results. This in turn causes impairment in the renal function with subsequent dilatation in the ureters and renal pelves, as can often be demonstrated by intravenous pyelography. Into this picture infection is readily introduced—a complication with serious potentialities. It is these consequences of bladder-neck obstruction which are responsible for the symptoms. Increased frequency of micturition is a common but by no means constant symptom. For example, it is often absent in one of the most serious types of case—that of the man with an atonic distended bladder. When the obstruction is well established the frequency is due to the presence of a residual urine, which causes a diminished bladder capacity. In early cases, however, there may be frequency with little or no residual urine, and this is explained by the enlarged gland interfering with the mechanism of the internal sphincter—urine, in consequence, being constantly present in the posterior urethra; or the trigone may be elevated as a result of the increased size of the prostate and thereby under constant stimulation to initiate the act. Frequency may also be due to a coincident cystitis resulting from a urinary infection. It is noticed chiefly at night, interrupting sleep perhaps two or three times, and in advanced cases much oftener.

Difficulty of micturition is a variable symptom, and is in no way related to the size of the enlargement. There is often delay in starting the act, particularly at the initial morning effort or when the call to micturate has been too

long neglected. Such neglect may precipitate acute retention. Thus it is common to hear of attacks of retention following a motor run, particularly when the presence of ladies has prevented a self-conscious sufferer from seeking relief. Excessive drinking and exposure to a cold or wet atmosphere are other predisposing causes of retention, the superadded congestion of the already enlarged prostate resulting from these conditions being sufficient to bring about a complete hold-up. In the absence of retention, pain is not a prominent symptom unless a bladder calculus is complicating the picture, in which event interruption of the stream may be a feature. Such an interruption may also occur when a middle-lobe enlargement projects over the internal meatus. Haematuria, when present, is often associated with a massive soft, friable type of gland.

These symptoms are well known and make a potential diagnosis of prostatic obstruction fairly easy. There is, however, a syndrome that may easily be missed though the life of the patient affected is often in jeopardy. I refer to the man who has slowly developed an increasing degree of chronic retention. The process may have been so gradual that no alteration in the bladder function is complained of. Direct questioning may elicit the admission that there has been a loss of projectile force in the stream. There may be little or no nocturnal disturbance, but involuntary leakage during sleep is sometimes experienced. Advice is sought because of a persistently dry tongue and a constant thirst. There has been inability to concentrate, loss of weight, a poor appetite, increasing constipation, and the skin has a dry, yellowish colouring. These are uraemic manifestations, due to back-pressure effects of long standing from the distended bladder; but the symptoms are so suggestive of a gastric lesion or of chronic intestinal obstruction that the underlying cause is easily overlooked and time is wasted in referring the patient for investigation of his gastro-intestinal tract. When complaints of this nature are made by a man in the prostatic age group—and remember this may occasionally include those under 50 years of age—the abdomen should at once be examined for evidence of vesical distension.

Indications for Operation

Operations on the prostate are required not because of enlargement of the gland but on account of the necessity for relieving obstruction at the vesical outlet. The pathological conditions of the prostate might in themselves be regarded as trivial, but the effects on the urinary tract may prove disastrous. It follows, therefore, that it is the degree of obstruction present and not the size of the prostate that constitutes the chief indication for operation. In many, the need for operation is self-evident. Thus the patient who is subject to recurring attacks of retention, who has a persistent complete retention, or who has a chronic vesical distension obviously requires operation. So also does the man who experiences a delay in initiating the act of voiding and accomplishes it with difficulty and with diminished volume. It is less easy to dogmatize about the treatment of a patient with minor prostatic symptoms.

Men who have reached the prostatic age often seek advice because of some disturbance in micturition. They are aware of the prostate and the possibilities which may ensue from it. They wonder whether something needs to be done, as they are rising once or occasionally twice during the night and are experiencing a slight hesitancy in starting micturition. Rectal examination reveals a slight enlargement of the gland, but the bladder is being emptied except for an ounce or so of residual urine, which amount is obtained on catheterization immediately after voiding. It is quite unjustifiable to advise operation for these patients. They do not, and may never, require it. With all our

*A B.M.A. Lecture delivered to the North Staffordshire Division at Stoke-on-Trent on Dec. 4, 1947.

advances in technique, prostatectomy by any method is not indicated as a prophylactic measure.

On the other hand, a patient in the early sixties with a diminished force in the urinary stream, a residual urine of 3 or 4 oz. (85-115 ml.) and well-defined enlargement of the gland, should have operation, though one in the late seventies with similar findings might best be left alone. The probable longevity with the younger age group is such that, the obstruction having established itself, it is likely to be progressive, and as operation is almost certain to be necessary sooner or later it is best that it should be done whilst he is a "good risk." The patients in the older age group should be kept under observation, and if an increasing degree of bladder distension takes place operation will be indicated irrespective of age. It is impossible to lay down hard-and-fast rules for these patients, and each must be judged individually. Some to whom I have recommended operation and who declined have, to my knowledge, carried on without added discomfort for years. Others whom I have advised that operation was not indicated have subsequently come under my care with retention. There is really no way of definitely predicting the future course of events following the commencement of early prostatic symptoms. A delay of six months or more before forming a conclusion will result in no harm to the patient, provided that damage to the kidneys is not occurring as a result of back pressure from an increasingly distended bladder.

Recent Innovations in Operative Treatment

The normal prostate is an extravascular structure. One that is enlarged is still so, though it may intrude into the bladder to a greater or lesser degree. In the case of the prostatic bar, the site of the obstruction is at the bladder neck. It is therefore not surprising that an extravascular approach through the perineum has vied for many years with an intravesical approach by way of the suprapubic route as a method of choice in operating for the relief of prostatic obstruction. It is also natural that instruments for excising the small amount of tissue which constitutes a prostatic bar should have been devised to give access to the obstruction by way of the urethra and that from these original prostatic-bar excisors an armamentarium has been developed which in trained and skilled hands makes possible the removal of a prostatic enlargement or a substantial portion of it. Thus during the past fifteen years or so the transurethral route has become a third recognized method of approach to the prostate.

The underlying motif that has stimulated differing operative efforts has been the need for a procedure which will give relief to a group of patients who, as a rule, are not ideal subjects for operation because of their age and the coincident cardiovascular, pulmonary, and renal pathology that frequently accompanies the prostatic lesion. It is an unfortunate circumstance that major surgical intervention requires to be carried out when degenerative changes have become established. I have never practised perineal prostatectomy, but have been an active exponent of the suprapubic operations, using the techniques of Freyer, Thomson-Walker, and Harris as these succeeded each other. I have also employed the transurethral method since its inception, but have tended to restrict its use to the smaller types of enlargement. One felt that every possible mode of access to the prostate had been explored and that good results depended on careful timing of operation after adequate preparation of the patient, particularly in regard to improvement of renal function; on selecting the approach most suitable to the variety of prostatic obstruction present; on perfecting one's operative technique and planning a careful regime of post-operative care. In latter years judicious use of the sulphonamides and penicillin has given further

aid. Of great importance also has been the help we have had from some of the newer methods of anaesthesia.

But urology, as an American colleague has stated, is dynamic specialty, and the search for still further improvements stimulated the ingenuity of Terence Millin (194, 1947) to devise yet a fourth approach. Two years ago he published his method of prostatectomy, for which he claimed not only a low mortality but also an absence of the variable difficulties, complications, and post-operative discomforts that may beset the other three methods, as well as a short confinement to bed and a rapid convalescence. Briefly, the technique is as follows.

The retropubic space behind the symphysis is exposed through a low abdominal incision, either transverse or vertical in direction. The prostate gland within its capsular coverings is defined below the bladder, cleared of overlying fat, and the capsule then opened by a transverse incision immediately distal to the bladder neck. The lower extremities of the lateral lobes are freed with scissors and the separation is continued with the finger, working from below upwards until both lateral lobes and the middle lobe, when present, are delivered into the wound, when the complete adenomatous mass can be readily detached. A wedge from the posterior lip of the vesical neck is now excised, this being an essential step in the operation to obviate stricture subsequently occurring at the vesico-urethral outlet. The cavity is carefully inspected, spurting vessels are caught in forceps and coagulated with the diathermy, and any small residual adenomata or loose tags removed with scissors so that a smooth surface remains. A catheter is then passed along the urethra into the bladder and the prostatic capsule is closed by catgut suture. Sulphanilamide powder is inserted into the retropubic space and the wound closed, a small drain of corrugated rubber being delivered through it. The drainage from the catheter must be carefully watched, particularly during the first six hours, to ensure that there is no blockage from clots. The patient is generally able to get up on the third or fourth day and to void urine on the fourth or fifth day, when the catheter is removed. The majority of patients are ready to go home within about a fortnight from the time of operation.

I can comment on this operation with some knowledge for I have personally employed it on 205 patients. Its execution is a more difficult technical undertaking than the suprapubic operation, but with experience it can be accomplished within 30 minutes and with little blood loss. The patient should have a painless convalescence with, in the majority of instances, no suprapubic seepage of urine at all. Included in my series are patients with serious cardiovascular lesions and permanent renal damage who would formerly have been regarded as unsuitable for prostatectomy. Seventy-five had passed their 70th birthday, 2 being between 75 and 83 years of age. In spite of including this "bad-risk" type of case, my overall post-operative mortality has been 7.2%.

Another new mode of procedure has been described by Wilson Hey (1945). His advocacy is startling, not so much because of his method of operation, which is through the suprapubic route, but because of the principles he enunciates, principles which condemn that which for many years has been regarded as dogma in the treatment of the prostatic. He advocates immediate prostatectomy on a patient with acute retention, and prostatectomy without preliminary drainage on the patient with chronic retention even if he be uraemic. Now, this latter group of patients is generally regarded with the greatest anxiety, as it is believed that the presence of renal impairment prostatectomy will aggravate the kidney failure. The renal function, it is considered must first of all be adequately restored by a preliminary period of bladder drainage, the indwelling catheter being employed for this if a week or two of drainage will suffice a suprapubic tube if more prolonged drainage is required. Hey, however, considers that these measures are potent means of introducing infection into the urinary tract.

adding a new infection, and it is this, and consequent pyelonephritis, that is responsible for the mortality. He therefore condemns the preliminary use of the catheter or suprapubic tube and, following such supportive and anti-septic treatment as the timing of his operation will permit, carries out a bimanual enucleation of the prostate by the suprapubic route, removing at the same time a substantial segment of the bladder trigone. The large cavity which is thereby left permits visualization of bleeding points, and meticulous haemostasis is obtained by diathermy of these. It is thus possible to close the bladder completely, after passing a tube down the urethra in a retrograde direction. Hey claims a low mortality, early ambulation, and a short stay in hospital for his method also. I have used his operation on 43 patients, selecting for the most part those suffering from chronic distension and consequent marked renal impairment. There were three post-operative deaths.

Hey has, I consider, certainly produced a strong case for his contention that the introduction of sepsis into the urinary tract and subsequent renal infection is a chief source of danger in prostatectomy. It is, however, difficult to admit his claim that it is, for example, safer to perform a prostatectomy on a man with uraemia, a gross urinary infection, and a severe secondary anaemia than to carry out the operation after these conditions have been righted, even though the time required to bring about the necessary improvements will call for preliminary drainage of the bladder.

Suprapubic Cystostomy

The establishment of permanent suprapubic drainage as a method of relieving prostatic obstruction is highly undesirable, and indeed must be regarded as a confession of failure. As a temporary measure to relieve acute or chronic retention, however, I consider the procedure still has a useful role to fulfil, particularly when there is gross renal impairment associated with severe secondary anaemia, or when a serious cardiac lesion is present which time and supportive treatment might improve. The drainage, by relieving the upper urinary tract of back pressure, will generally be followed by a betterment of the renal function. When this preparatory measure has resulted in the maximum improvement that can be achieved, the surgical attack on the prostate can be proceeded with. In some instances little or no improvement in the kidney function takes place. This may be because the kidney damage is so advanced as to be irreversible, or it may be due to compression of the lower ends of the ureters by the enlarged prostate. That this can happen may be demonstrated at operation, when following removal of the gland—usually one that is markedly enlarged—through the suprapubic route, urine can sometimes be observed gushing out of the ureteral mouths.

The optimum improvement likely to follow in those on whom cystostomy has been deemed expedient will occur in from one to three months. After that time there are but few who should not be offered operation. Some may be content to carry on with a permanent tube, but most will gladly accept operation, even if this is not without hazard, in preference to being relegated to that unhappy group of men, "the permanent cystostomized and abandoned prosthetic." There are, of course, those who develop urinary obstruction, who are already in a stage of terminal physical and mental dissolution, or who suffer from some other lesion of a mortal nature. The insertion of a suprapubic tube under local analgesia is all that is indicated as a means of easing their remaining days. Out of 310 operations for prostatic obstruction that I have carried out during the past two years, cystostomy was the sole procedure in 11. One patient with congestive cardiac failure died within 48 hours.

Eight lived for periods of one to six months and two still survive.

Treatment of Prostatic Carcinoma

The incidence of the malignant prostate is high, accounting for about 16% of all prostatic obstructions. Now, there are several ways of carrying out a radical operation for prostatic carcinoma, the perineal, retropubic, and suprapubic routes each offering an alternative method. Only, however, in the earliest cases will such operations hold out the prospect of cure. When the gland by its asymmetry, hardness, nodularity, or fixation is clinically recognizable as being malignant no radical operation can be offered. Into this group fall the large majority of patients suffering from prostatic carcinoma. The late Hugh Young (1945), of Baltimore, before his death published the results of his radical operation for the malignant prostate. These were on the whole excellent, the operative mortality being around 6% and a cure claimed for nearly 50%. One noted, however, that in the 40 years during which he had been carrying out the operation he had been able to employ it on only 184 patients.

I think the fact must be squarely faced that at the present time palliative treatment only is possible for the large majority. The outlook is brighter than formerly, however, as a result of oestrogen therapy, which is based on the knowledge that the cells of a prostatic cancer will atrophy if the supply of androgens is cut off. This process is achieved either by castration, which eliminates the main source of androgen, or by the administration of oestrogens or their synthetic equivalent, stilboestrol. The effect of oestrogen is to arrest the androgen output from the testicles by inhibiting the supply of gonadotrophin from the pituitary. Those of us who have been engaged in the clinical application of this treatment since its introduction recognize that it does not cure. From experience gained during the past five years I am not even prepared to state that it prolongs life, but it certainly eases it in a large proportion of sufferers. In those who are responsive to the treatment the nodularity and induration disappear in a matter of weeks, and micturition becomes easier and frequency less. Lumbar and sciatic pains, from which many suffer, disappear, and the patient generally has a new feeling of well-being. One patient, whom I saw for the first time after he had lost all power in both legs as a result of a metastatic deposit in the lumbar spine, was able to be up and about within two weeks of starting treatment, and now, after the elapse of a year, remains well enough to travel to his office daily. I have not obtained by the use of stilboestrol any measure of success in restoring normal micturition in cases with retention or severe obstructive symptoms, but a transurethral resection generally accomplishes this and obviates the necessity for a permanent cystostomy in the majority. Orchidectomy, the surgical method of reducing male hormone, is of proved value in the treatment of prostatic carcinoma and is probably quicker in action than the administration of oestrogens. The testicular substance from the body of each testicle can be readily shelled out through an incision in the tunica after delivering the testicles in turn through a small single incision made at the lower extremity of the scrotum. I generally employ the method if I require to carry out a resection for the relief of obstruction, performing the orchidectomy at the same time.

Thus my treatment at present for an established prostatic carcinoma is on the following lines. In the absence of obstructive symptoms, reliance is placed on stilboestrol therapy alone. The initial dosage is 5 mg. four times daily, this being continued until an adequate response occurs, when the amount is reduced to a level which appears to be adequate for control. About 3 mg. a day will generally

prove sufficient for this purpose. The optimum dosage has not yet been determined, but continuity of treatment is considered essential. When retention or severe obstructive symptoms necessitate a transurethral resection the opportunity is taken of removing the testicular substance and stilboestrol is withheld, to be used as a final measure if signs of reactivity manifest themselves.

Conclusion

The following table shows the different methods I have employed in a personal series of 310 consecutive operations for prostatic obstruction during the past two years:

Operations for Prostatic Obstruction, December, 1945, to November, 1947

Method of Operation	No.	Mortality
Retropublic prostatectomy	205 (7 2-stage)	15 (7.2%)
Prostatectomy by Wilson Hey technique .. .	43	3 (6.9%)
Suprapubic prostatectomy	10 (9 2-stage)	0 (0%)
Transurethral resection	41 (19 malignant)	1 (2.4%)
Suprapubic cystostomy	11	1 (9.0%)

It may seem strange that no single operation has been universally accepted as a standard method for the relief of prostatic obstruction. The variety of operative measures is, however, not so surprising if the varied prostatic pathology and the differing physical status of the individual patients is borne in mind. Because of this, I believe it is undesirable that one should be exclusively devoted to a single operation which all our prostatic patients must submit to.

Having served an apprenticeship in the surgery of the prostate, extending over a period in which many fundamental changes have been introduced in the surgical approach to this problem, I have learnt that one must not be reluctant to admit the necessity for change. Suggestions which do not accord with established ideas should be viewed critically, but not with distrust. If a new technique seems indicated the change must be made, even though a major effort is required to alter course and master its accomplishment.

LOWER-SEGMENT CAESAREAN SECTION A NEW HEAD EXTRACTOR

BY

BRYAN C. MURLESS, M.B., F.R.C.S., M.R.C.O.G.

Assistant Visiting Obstetrician and Gynaecologist, King Edward VIII Hospital, Durban

Incision of the lower uterine segment for delivery was first proposed by Frank as long ago as 1907. It was not until many years later that it became a recognized procedure and its true advantages were realized. To-day these advantages have been proved. The lower-segment section, with its decreased maternal mortality and morbidity rates, has come to stay. Few classical operations are now performed in the world's great clinics, and some authorities have not performed one for many years. It may almost be said that, except in special cases, classical caesarean section should be regarded as malpractice. It seems surprising, therefore, that the technique of delivering the head in the so-called lower-segment operation is still far from perfect. This is shown by the many different methods in use to-day,

for in a tour of operation theatres each surgeon may be seen to use his own pet manoeuvres.

To my mind, delivery of the head has always been the most difficult part of the operation, especially for inexperienced surgeons. I have therefore tried to devise an instrument to simplify this procedure.

Methods for Delivering the Head

Several methods have been used for delivering the head—e.g., Willett's forceps, a single blade of the large obstetric forceps, Wrigley's forceps, small straight forceps, and the operator's hand. I submit that each of them has its disadvantages.

Willett's Forceps.—The obvious disadvantage of scalp traction with Willett's forceps is damage to the foetal scalp. This may not be severe, but it is a circumstance to be avoided if better methods are at hand. Sepsis of the scalp may follow and cases of *Clostridium welchii* infection with serious results have been reported. Furthermore, the lifting power on the foetal head, through the scalp, is not all that could be desired, and haemorrhage from the uterine incision cannot always be controlled by the upward pressure of the foetal head. Most operators have abandoned the use of Willett's forceps in favour of other methods.

Single Blade of Large Obstetric Forceps.—A single forceps blade is sometimes used as a lever to deliver the head. This method is unsatisfactory, as the lack of curve of the blade makes it extremely hard to introduce if the head is engaged. Again, if it can be introduced successfully the leverage is in the wrong direction, with resulting tears of the lower segment.

Wrigley's Forceps.—These are used by many surgeons at the present time. They are not completely satisfactory and are sometimes difficult to apply. The chief disadvantage is that haemorrhage may take place while the head is being manoeuvred into position and the forceps are being applied—a procedure that can take a considerable time even with an expert operator.

Small Straight Forceps.—Straight forceps are generally easier to apply than Wrigley's forceps, but the disadvantage mentioned above still applies. Small straight forceps are perhaps the best method of delivery in use at present, but they are still far from the ideal.

Operator's Hand.—Many operators use their hand to scoop the head out of the uterine incision. In my experience it is always necessary to introduce four fingers and the whole of the palm of the hand into the uterus to get below the foetal head. It is a "blind" method of delivery and serious tearing of the lower segment may result, endangering the uterine vessels, no matter how carefully the manipulation is done. To onlookers the method appears clumsy, and the unnecessary introduction of the whole hand into what may be the infected area offends the principles of surgery.

The Extractor

An instrument fashioned like a forceps blade, which curves round the foetal head just above the symphysis pubis and gently lifts the head out of the uterus, would, it seemed, be ideal. It was soon found that a blade with the correct curve and a fixed handle was impossible to introduce owing to contact of the handle with the anterior abdominal wall thrown forward by the pregnant uterus. A blade with a detachable handle was therefore made and it worked successfully. Finally, the instrument described below with a handle that folds back on a double hinge was designed.

The instrument consists of a single fenestrated blade the shape of which is very similar to that in the ordinary midwifery forceps, except for an exaggerated cephalic curve. Immediately at the base of the blade is a double hinge built into the normal diameter of the shaft connecting the blade to the handle. The shaft carries a sliding sleeve which by a simple movement covers and locks the double hinge, thus

converting the instrument into one piece and making the blade rigid with the handle.

Technique of Operation

The abdomen is opened by a subumbilical incision in the midline. A self-retaining retractor is inserted and the operation area packed off with a gauze roll in the usual way. A 2-in. (5-cm.) transverse incision is made through the uterine wall where the loose peritoneum is reflected from the bladder. The lower edge of the uterine incision is grasped with a vulsellum forceps and raised from the foetal head. With the handle folded back the curved blade of the extractor, lubricated with "dettol" cream, is introduced between the lower edge of the incision and the head. As it slides round the head the handle is straightened out and the hinge locked.

The assistant now takes the extractor in his left hand and gently lifts the foetal head against the uterine wall. The sucker in his right hand keeps the field clear of liquor. The surgeon now enlarges the incision at either end with scissor snips, at the same time applying fundal pressure with his other hand. There is usually no bleeding, but any vessels that are seen to be cut may be clamped with de Martel's forceps to forestall haemorrhage when the head is out. When the incision is large enough the head is slowly delivered by fundal pressure and the lift of the extractor. The operation is then completed in the usual manner.

Before labour, when the head is not engaged, the whole procedure is extremely simple. Under certain conditions modifications of the technique may be necessary. If during labour the bladder is raised on the lower segment the peritoneal reflection is incised separately and the bladder pushed down before the uterus is incised. If the head is deeply engaged in the pelvis it may be necessary to disimpact it by inserting two fingers into the uterus and pushing the head up before the extractor can be introduced. While the fingers are holding the head the extractor is introduced between the fingers and the lower edge of the uterine incision and slid into position before the fingers are withdrawn.

Once the extractor is in place the operator's difficulties are over. If the head lies in the transverse position it is turned to an occipito-anterior or, should it be easier, to an occipito-posterior position, when the foetal chin is slipped over the upper edge of the uterine incision and the head eased out with the extractor as a "face presentation."

Advantages of Extractor.—(1) The most striking advantage claimed for this instrument is the absence of haemorrhage during delivery of the head. Consequently the uterine incision can be enlarged bit by bit, the whole time under direct vision. The incision is therefore never made unnecessarily large. (2) Tearing the uterus should not occur, as delivery is slow and under complete control. Under these conditions unsuspected damage to the uterine vessels should be impossible. (3) If difficulty is experienced in turning the head it can be lifted out in any position. This is not possible when delivering with forceps, as they cannot be applied if the head lies in the transverse diameter. (4) The foetal skull is subject to a minimum of pressure, which is probably less than that of normal labour. Head injuries should therefore be extremely rare. This is not always so after a hurried delivery by the operator's hand or the small forceps. (5) With the use of the extractor the operation becomes a neat surgical procedure. This cannot be claimed for most other methods of delivery in use at present.

Discussion

The instrument has now been tested in over a hundred cases. When the head is not engaged it has been found universally satisfactory and easy to introduce. If the head is low a little practice is needed to introduce the extractor successfully, but it is found that the head can nearly always be raised enough to make this possible, though it may be necessary to enlarge the uterine incision. The extractor has not been tested in extraperitoneal section, as since penicillin has been in good supply I have not used this method, but it might prove a useful adjunct in this operation.

This report is published in the hope that the extractor will be tried out and improved by others, and that its routine use may simplify what most surgeons still regard as a difficult manoeuvre.

Summary

A new head extractor for low caesarean section is described. Other methods of delivering the head are discussed. The technique of using this instrument is described, with the modifications necessary in certain circumstances. Advantages claimed for the extractor are listed.

(The instrument was made by the Surgical Division of Allen and Hanburys (Africa) Limited, and will be obtainable through Allen and Hanburys, Wigmore Street, London.)

PAPILLOMATA OF BLADDER TREATED WITH PODOPHYLLIN PRELIMINARY REPORT

BY

J. E. SEMPLE, M.D., F.R.C.S.

Honorary Surgeon, St. Paul's Hospital for Urological
and Skin Diseases, London

In 1942 Kaplan reported a series of cases of genital warts successfully treated with a suspension of podophyllin in mineral oil. The application of this drug to meatal and urethral papillomata revealed an apparent resistance of normal transitional epithelium to its caustic action; this suggested the possibility of its use in treating papillomata of the bladder. After a preliminary investigation a suspension of the drug in liquid paraffin was used in the following cases.

Case Reports

Case 1.—A man aged 73 had had haematuria for several months, which had been severe for the last 13 days. Cystoscopy showed numerous large papillomata involving the right

lateral and the posterior walls of the bladder, too extensive for perurethral fulguration. The general condition of the patient contraindicated cystostomy and open fulguration. Five instillations of podophyllin in liquid paraffin were carried out twice weekly in strengths increasing from 1 to 12%. During these applications the normal mucosa of the urethra and bladder showed no reaction to the drug. Haematuria ceased after the first instillation. After the fifth the growths had diminished in size to a small patch of sessile papillae above the right ureteric orifice, where it was easily fulgurated per urethra. After one year the patient has had no recurrence. The bladder and urethra show no ill effects from contact with the drug.

Case 2.—A man aged 30 had had haematuria on and off for three years with marked anaemia. Cystoscopy showed multiple papillomata involving the posterior and left lateral walls of the bladder, too extensive for perurethral fulguration. Histological section revealed benign papillomata. Four instillations of podophyllin in liquid paraffin increasing in strength from 1 to 8% were carried out in the course of four weeks. There was no reaction of the bladder or urethral mucosa as seen on cystoscopy and urethroscopy. After the fourth application the papillomata showed areas of sloughing and the growths were much diminished in size. The growths were completely cleared from the bladder after three fulgurations in the out-patient department.

Case 3.—A man aged 72 first noticed haematuria two weeks before I saw him. On cystoscopy a large papilloma about 2.5 cm. in diameter, as estimated by the scale on a ureteric catheter, was seen above the left ureteric orifice. Two instillations of podophyllin in liquid paraffin of 4 and 10% were carried out without any discomfort. Three weeks after the second application the tumour had shrunk enough to allow the growth to be fulgurated at one sitting.

Case 4.—A man aged 44 had had haematuria for three weeks. On cystoscopy a simple papilloma above the left ureteric orifice about 1.5 cm. in diameter was seen. In the out-patient department 5 ml. of podophyllin in liquid paraffin was instilled into the bladder. No discomfort resulted from the application. Three weeks later the papilloma had shrunk considerably and appeared much atrophied. The base was fulgurated per urethram.

Technique

The method that has evolved from the above cases is that at the end of diagnostic cystoscopy the window of the cystoscope is placed immediately over the growth and the bladder is emptied. Then 3 ml. of 0.5 to 1% podophyllin in liquid paraffin is introduced into the bladder through the instrument direct on to the papilloma. The telescope is then inserted to empty the sheath of the oil and for its withdrawal. The patient is turned on to the side on which the growth is situated and lies thus for half an hour, by which time urine will have collected in the bladder and will tend to float the oil off the tumour. In order to maintain the contact of the suspension with the papilloma the patient is turned on to the opposite side, and remains there for as long as possible. He is encouraged to empty his bladder when the urge arises, as a result of which nearly all the podophyllin will be expelled. Even if this expulsion is not complete the bladder mucosa is not apparently injured.

The initial minimal dose is used to test the susceptibility of the patient and the potency of the drug, the latter varying greatly in different samples. Provided no reaction occurs, an instillation of an effective dose of 5 ml. of 4% podophyllin in liquid paraffin is introduced through the cystoscope four to seven days later, the patient lying on alternate sides as before. A week later a third application is carried out through the cystoscope, using 5 ml. of 8% podophyllin in liquid paraffin. Further applications can be made depending on the size and extent of the growth. Perurethral fulguration is used to complete the destruction of the new growth.

Discussion

The commercial podophyllin powder is a mixture of resins produced from the American and Indian podophyllum rhizome by alcoholic extraction and water precipitation. Merck's *Index* states that the resin contains picropodophyllin, quercitrin, podophylloresin, and podophyllotoxin. The active principle of the cutaneous application has not been determined. Haber (1945) suggests that an alkaline secretion of the wart converts podophyllotoxin into podophyll acid, which coagulates the wart. Sullivan and Wechsler (1947) have caused the disappearance of the wart with filtered aqueous extract of podophyllin.

The mode of action is also debated. Culp and Kaplan (1944) suggest that degeneration is produced by spasm of the smaller vessels owing to irritation of the drug. Sullivan and Wechsler, investigating its cytological action on the growing root of the onion, found that it had a marked effect on the chromosomes of the nuclei, causing increased mitotic figures in the metaphase and later the decrease and complete absence of the anaphase and telophase figures. King and Sullivan (1947) showed that the action of podophyllin and colchicine on the skin was similar, causing varying degrees of destruction of cells, mainly in the deeper part of the prickle-cell layer, some being completely destroyed as shown by shrunken eosinophilic cytoplasm and pyknotic nuclei, while others reveal swollen basophilic reticulated cytoplasm, thickened cell membranes, diminished or absent intercellular bridges, peripheral or perinuclear vacuolation of the cytoplasm, and changes in the nuclei, which these authors interpreted as abortive and not as true variations of mitosis (so-called podophyllin cells).

The only warts that resist podophyllin are those which are extensively keratinized; it might therefore be expected that the delicate epithelium of a bladder papilloma would be affected by this drug. In three of the cases reported, the size and extent of the new growths would normally have necessitated open fulguration, but after a few applications of podophyllin they had decreased to a size that allowed them to be successfully fulgurated per urethram. The fourth case showed marked degeneration of the papilloma, so that the base alone required fulguration. There have been no immediate or remote ill effects following the application of this drug in those cases which have been observed for over a year, nor has there been any evidence on cystoscopy or urethroscopy of any reaction of the normal bladder or urethral mucosa. Colchicine is said to be superior to podophyllin in its action on the skin; but further investigation of this drug is required before extending its use. Other vehicles besides liquid paraffin have been tried with the object of improving the application of the suspension to the new growth, such as using an oil heavier than water, but without improving the results.

The results obtained by the application of podophyllin to papillomata of the bladder are encouraging enough to warrant a further trial of this drug or of drugs having a similar action (such as colchicine, auramine, urethane, and sodium cacodylate (Ludford, 1936)).

Summary and Conclusions

Four cases of papillomata of the bladder treated with podophyllin in liquid paraffin applied direct to the new growth through a cystoscope are reported and the technique is described. Three of these cases would have required cystostomy and open fulguration, but after a few applications of podophyllin the extent and size of the tumours had diminished so that they were successfully treated by perurethral fulguration. The fourth case showed marked atrophy of the growth, so that perurethral fulguration of the base of the papilloma was alone required.

The number of cases in which this method has been carried out is too small to allow any definite conclusions to be drawn.

CASE OF SARCOMA OF THE LARYNX

but the results appear to warrant further trial of this drug and those allied to it in action.

CASE OF SARCOMA OF THE LARYNX

BY
E. BROUGHTON-BARNES, F.R.C.S.
Honorary Consulting E.N.T. Surgeon
E. S. DUTHIE, M.B., B.Ch., Ph.D.
Late Pathologist

AND
B. JOLLES, M.D., D.M.R.
Consultant Radiotherapist
General Hospital, Northampton

Tumours other than squamous-cell epithelioma of the larynx are rare. According to Havens and Parkhill (1941) 26 cases were encountered at the Mayo Clinic during a period of 30 years. These included four cases of sarcoma previously reported by New (1935). During that period 1,100 malignant and 722 benign tumours of the larynx were examined at the Mayo Clinic. Of the 26 malignant non-squamous-cell tumours 11 were cases of sarcoma, 8 of haemangio-endothelioma, 5 of adenocarcinoma, 1 of melano-epithelioma, and 1 of myeloma. Of the 11 cases of sarcoma 8 were diagnosed as fibrosarcoma, including fibromyxosarcoma. 2 as chondrosarcoma, and 1 as rhabdomyosarcoma. The ratio of all other types of malignant disease of the larynx to squamous-cell epithelioma of the same organ was 1:44, and the ratio of sarcoma to carcinoma was approximately 1:100.

This is at variance with Ewing (1928), who stated that sarcomas form about 11% of malignant laryngeal growths. Ewing added, however, that "many cases recorded as sarcomas are of epithelial origin." In Jackson and Coates' (1929) series of 643 malignant tumours of the larynx, one case of true sarcoma was found, and Thomson and Colledge (1930), in a wide experience, have seen only one case of sarcoma. Clerf (1946), from the Jefferson Hospital, Philadelphia, where, since 1930, 740 cases of carcinoma of larynx were seen, reported 8 cases of sarcoma (4 fibrosarcoma), and notes that 7 further cases have been added to the literature since Havens and Parkhill's report. A ratio of 1:100 of sarcoma to carcinoma is probably not far off the mark.

Sarcoma of the larynx is a localized tumour with little tendency to infiltrate underlying and surrounding tissues. It is very often pedunculated, but in some cases erosion of its surface is not observed. The sites of predilection of the surface can be observed. The sites of predilection of the surface of the larynx are the true vocal cords. Metastases are very uncommon, recurrences less so. The size of the tumour varies, but generally it is bigger than that of carcinoma. The symptom most frequently present is huskiness, and the mechanical obstruction causes dyspnoea only rarely.

In two out of the four cases described by Figi (1933) an emergency tracheotomy had to be performed. Dysphagia is rare except in cases involving the epiglottis or when the tumour occludes the hypopharynx. A history of influenza

or acute or chronic chest troubles immediately before the finding of a tumour of the larynx is often encountered.

Histologically, according to the presence of a variety of mesodermic structures, fibromyxosarcoma, chondrosarcoma, and rhabdomyosarcoma can be distinguished. In an irregular pattern of spindle or round cells arranged in cells can be seen. The blood vessels are often scanty and small. The cell nuclei are small and spindle-shaped, but in some tumours round nuclei can be seen.

The treatment is usually on surgical lines. According to the degree of differentiation of the tumour, and its cellular population, the question of post-operative or "radical" radiotherapy has to be considered. Simple punching of the tumour with direct or indirect laryngoscopy followed by electrocoagulation of the point of attachment of the tumour, although feasible in some cases, is not satisfactory. Laryngofissure is adequate even in cases in which on first inspection, the size of the tumour rules this procedure out.

The prognosis in sarcoma of the larynx is relatively good. Of the 11 cases of sarcoma at the Mayo Clinic (Havens and Parkhill, 1941) 9 were treated principally by surgical operation and 2 with radium—8 patients were alive and well (6 for more than five years), 2 died without recurrence, and 1 died with recurrence. In Clerf's series 2 were living for over five years, 3 died of intercurrent disease, 1 died of local recurrence and metastases in the lung, and 2 were observed for only a few months post-operatively.

Case Report

The patient was a man aged 66. On May 12, 1943, he reported huskiness of a few weeks' duration and some difficulty on swallowing since December, 1942. A smooth, mobile, semi-pedunculated wet-looking tumour, 0.8 cm. across, was found in the middle of the right true vocal cord. The movements of both vocal cords were normal and full. On June 1 the tumour was removed by diathermy (E.B.B.) and the piece sent for section.

The pathological report (E.S.D.) was "sarcoma, probably fibromyxosarcoma." This section was also seen by Dr. A. H. T. Robb-Smith, Radcliffe Infirmary, Oxford, who concurred in the diagnosis of fibromyxosarcoma. The patient was followed up, and was well until November, 1943, when, after a bout of influenza, he started complaining of huskiness again, and a small nodule reappeared in the middle of the right vocal cord, which was now limited in its movements. The tumour was hard and nodular, roughly circular, and measured 0.7 cm. each way. On Jan. 11, 1944, a laryngofissure was performed (E.B.B.). Post-operative deep x-ray treatment was given (B.J.). The section of the removed tumour was seen by Mr. D. Harmer and the late Dr. J. C. Mottram, of Mount Vernon Hospital, Northwood, who also concurred with the original report of fibrosarcoma. The patient was well on Jan. 11, 1948, and, except for slight thickening of the right vocal cord and anterior commissure, there was nothing abnormal in his larynx.

Sponsored by the Mexican Government and the British Council. Dr. Luis Vargas is spending six weeks in Britain to study Mexican and neotropical mosquito and blackfly specimens in the Natural History Museum. Dr. Vargas is chief parasitologist in the medical science division of Mexico University Graduate School, and laboratory-of-entomology chief in the Institute of Public Health and Tropical Diseases.

Medical Memoranda

A Simplified Method for the Estimation of Chloroform in Blood

Small amounts of chloroform may readily be estimated by the colorimetric reaction with pyridine and caustic alkali (Fujiwara, 1914; Daroga and Pollard, 1941; Habgood and Powell, 1945). The normal procedure is to recover the chloroform from blood by steam distillation. This is time-consuming and requires ground-glass apparatus, which is now difficult to procure. The present method utilizes Conway's microdiffusion technique (Conway, 1947) and is both simple and rapid; 10 to 20 estimations may be performed in $1\frac{1}{2}$ to $2\frac{1}{2}$ hours, and require only 1 to 2 ml. of blood.

The principle is very simple. Undiluted blood is placed in the outer compartment of the diffusion cell and toluene in the centre compartment. The cell is sealed and, on standing, the chloroform distributes itself so that its vapour pressure in the blood, toluene, and air phases is equal; and, since the Conway cells provide a large liquid surface compared with the volumes used, this occurs rapidly. Now chloroform is some 100 times as soluble in toluene as in blood, so the vapour pressure of chloroform in toluene is $1/100$ that in blood; hence with the volumes used here about 96 to 97% of chloroform will be transferred to the toluene at equilibrium. At room temperature (20°C .) the equilibrium is 95% complete in 3 to 4 hours, but at 37°C . the equilibrium is 95% complete in 15 minutes, and 99% complete in 45 minutes if 1 ml. of blood is used; it is 80% complete in 15 minutes and 98% complete in 45 minutes if 2 ml. of blood is used.

REAGENTS

Toluene.—Pure toluene is shaken with concentrated sulphuric acid to remove thiophene, and then twice distilled, the middle fraction boiling at 115°C . being retained.

Pyridine.—Analytical grade or redistilled. It must be quite clear and colourless.

20% Sodium Hydroxide.

Diffusion Unit Fixative.—Five g. of gum tragacanth is ground with 70 ml. of distilled water to a smooth jelly and 25 ml. of glycerol is then added.

METHOD

Toluene 0.8 ml. is pipetted in the centre compartment of a standard Conway unit (obtainable from A. Gallenkamp, Ltd., Finsbury Square, London); 1 or 2 ml. of whole blood collected with suitable precautions (no oil in the syringe; narrow tubes filled to the top, and closed with a cork covered with silver foil) is rapidly pipetted into the outer compartment and quickly

Chart showing that the intensity of the colour obtained (1-cm. cell) increases linearly as the concentration of chloroform in the blood is increased.

spread with the tip of the pipette. The cover, which has been impregnated with fixative, is applied and the whole unit placed in an incubator at 37°C . for 50–60 minutes. The unit is then removed from the incubator, uncovered, and 0.5 ml. of toluene from the centre compartment transferred to 5 ml. of pyridine in a test-tube. Now 2.5 ml. of 20% sodium hydroxide is added, the

tube is agitated and then placed in a boiling-water bath precisely 5 minutes. It is then cooled in iced water, and, cool, 5 ml. of the supernatant pyridine layer is transferred to a clean tube and 1 ml. of water added to remove the turbidity. The resulting purplish-red colour is stable for about one hour.

The colour is measured in a colorimeter with an Ilfo micro-3 green filter, setting to zero with a blank. The intensity of absorption is linear with concentration (see Chart). Normal 1-cm. cells are used, but for concentrations below 5 mg. per 100 ml., cells of 2 to 4 cm. should be used if available. The absolute values for the absorption vary somewhat with different batches of pyridine, but owing to the linearity of the absorptive curve the slope of the line can readily be checked by running a few standards.

RESULTS

Chloroform in blood can be estimated in concentrations 0.5 to 35 mg. per 100 ml., the concentrations likely to be found during and following anaesthesia, with an accuracy of $\pm 5\%$. The method is applicable without modification to estimations in urine, cerebrospinal fluid, and tissue extracts.

The method has also been applied to the estimation of trichlorethylene. The colour obtained here with pyridine-sodium hydroxide is orange-red, with an extinction approximately one-third that of chloroform. Since the concentration of trichlorethylene found in blood during anaesthesia is only 6 to 12.5 mg. per 100 ml. (Powell, 1945) the colours obtained are rather feeble and the use of 4-cm. cells is essential.

Similar Obstetric Behaviour in Identical Twins

Two primiparous identical twin patients were confined within three weeks of each other at the same hospital, both having extended breech presentation, failed version, and toxæmia. It may be of interest to publish the histories of these cases, if only as a "curiosity."

CASE HISTORIES

The patients were the only children of their mother and were stated to have been born three to four weeks early, with no history of maternal toxæmia, "about 7 lb. (3.18 kg.) the two," and "both in the same-afterbirth." An aunt of their father had had twins and their mother had a brother and sister who were twins.

In the present instance the patients were delivered of their first babies (one each) within three weeks of each other in the autumn of 1945. Both were referred to the hospital antenatal clinic five weeks before term (as calculated) with extended breech presentations, right sacro-anterior, confirmed by x-ray examination, each breech being deep in the pelvis. X-ray examination also showed normal shapes of the pelvic brim. In each case, a week later, version under general anaesthesia failed. The first started in labour two days and the second nine days after attempted version. Both had uneventful extended breech deliveries with episiotomy, the one baby weighing 4 lb. 14 oz. (2.21 kg.) and the other 4 lb. 2 oz. (1.87 kg.), being three and four weeks premature respectively. The babies went home when 5 lb. (2.27 kg.) in weight, being breast-fed three-hourly, and both mothers had normal puerperia.

When first seen at the clinic both mothers had blood pressures of 140/90. A week later the first was admitted with toxæmia, B.P. 160/100, but no albuminuria; this settled with rest. The second rested at home on account of a B.P. of 145/100 (after version) and was readmitted a week later in labour, with B.P. 150/105 and albuminuria. Both patients had had scarlet fever at the age of 6 and were of stocky build (height 5 ft. 2 in.—157 cm.), as was their mother. Menses were regular 5/28 in both cases.

At the postnatal clinic (both failed to attend at the routine date!) the blood pressures were 160/90 and 150/100. They had no symptoms nor albuminuria and had each put on 2 stone (12.7 kg.) in weight nine months after delivery. Menses subsequently started again three and five months post partum.

I wish to thank Mr. Bryan L. Jeaffreson, consultant obstetrician, and Dr. James W. Affleck, acting medical superintendent, St. Mary's Infirmary, Leeds, for permission to publish these cases.

in medicine and surgery. This book accords with American concepts of the scope of physical medicine, which do not always coincide with ours. There is some repetition in the various chapters, and we should have welcomed articles on diagnosis and on the use of physical medicine in gynaecology and obstetrics.

W. TEGNER.

CARDIOLOGY ATLAS

Atlas of Cardiovascular Diseases. Correlation of Clinical Electrocardiography and Cardiac Roentgenology with Clinical History and Autopsy Findings. By Irving J. Treiger, M.D. (Pp. 180; 69 plates containing 244 illustrations; 11 in colour. 50s.) London: Henry Kimpton. 1947.

Cardiology is suitable for presentation in atlas form because the clinical and instrumental methods used are often complementary and the data they provide may be pieced together to establish the diagnosis. In this book Dr. Treiger is concerned principally to relate clinical, radiological, and electrocardiographic methods to necropsy findings. In the opening section he illustrates the normal heart, and he shows that there is no better way of demonstrating the significance of screening appearances in terms of the heart's anatomy and the cardiographic patterns depending upon the lie of the heart, its posture, rotations, and displacements. The photographs of specimens of morbid anatomy are clear, but the dozen or so coloured plates are on the whole less satisfactory. In a section on arteriosclerotic heart disease illustrations of opened hearts show at a glance how the position of a cardiac infarct is signified by special serial changes in the electrocardiogram and the corresponding radiographic configuration.

Each electrocardiogram includes a tracing from "lead IV" in addition to the usual limb leads. The chest lead is at the apex, but the author does not state whether the lead is C or F or V. Additional precordial leads would have provided information of interest in some of the cases. This work has obviously been planned chiefly to demonstrate common conditions; it is therefore a pity that congenital lesions are less well presented than others, now that diagnosis is becoming more precise and the scope of surgeons greater.

K. SHIRLEY SMITH.

SURGERY FOR STUDENTS

Textbook of General Surgery. By Warren H. Cole, M.D., F.A.C.S., and Robert Elman, M.D., F.A.C.S. Fifth edition. (Pp. 1,160; 558 figures. \$11.) New York: D. Appleton-Century Company. 1947.

There is no doubt that this is a very good textbook of surgery. In its fifth edition there are all the changes and additions necessary to bring the subject up to date. It is written for the undergraduate student, yet will surely be used also by post-graduates, practitioners, and practising surgeons. A feature which commends it to the latter classes of reader is the references to original papers on debatable and new aspects of surgery.

English students will want to know if it will serve their purpose as an undergraduate examination book. Like many of the books they are accustomed to read it is by a number of authors. This has the great advantage that we can rely on finding the opinions of authorities on any particular subject; on the other hand the writing and exposition are of uneven quality. All writers have not the same power of emphasizing the important facts and presenting them in a balanced way. Nothing could be more lucid than Ewart Graham's account of thoracic surgery, but other sections—for example, that on urinary diseases—are not treated as fully as our students are accustomed to. The new chapter on surgical convalescence is a welcome addition. Then again dualism is helpful in teaching the novice. Some of the authors here are almost hesitant, or at least unobtrusive, in their recommendations (as deep thinkers and great experts often are). Frequently they evade deciding on the best line of treatment by referring to the original sources. Perhaps the average American student is more apt than the British to consult original papers and monographs. The many illustrations are good and the layout of the book is excellent.

THE EPIDEMIOLOGY OF YELLOW FEVER

In spite of the general interest aroused by many of the medical discoveries which were made during the war, few troubled to speculate how it was that Allied operations were never impeded by outbreaks of yellow fever. This freedom from yellow fever was the more remarkable, for never before in the history of the world have so many potentially susceptible European soldiers had to campaign in lands where yellow fever is endemic.

The yellow fever zone in Africa is now known to extend from the southern border of the Sahara to the Barotseland, and from the Atlantic seaboard to the shores of the Red Sea and Indian Ocean. The East African campaign was thus fought out within the endemic yellow fever zone. Many hundreds of thousands of Allied soldiers and airmen tarried unwillingly in Freetown harbour, and at any rate in the earlier years of the war had ample opportunity of confirming the fact, originally demonstrated by Boyle¹ in 1831, that there was no berth in the harbour where one could be free from the ubiquitous mosquito.

From 1940 onwards the air route eastwards from the Gold Coast was one of the Allies' main lines of supply first for the Middle East and later for India and the Far East. To guard this air line as well as to train the junior of a million West Africans who voluntarily enlisted in the Armed Forces some fifty thousand Europeans from the Navy, Army, and Air Force spent a part of their war service in West Africa. Among all these troops—British, French, American and African—there were but four cases of yellow fever—one in an African sailor on the Gold Coast and three in European soldiers in Sierra Leone. Two of the four had almost certainly escaped inoculation against yellow fever. This freedom from yellow fever ever to the disappearance of the disease from Africa. In 1940 there occurred the largest epidemic of yellow fever ever recorded, an outbreak in the Nuba Mountains in the Anglo-Egyptian Sudan involving probably some 30,000 Sudanese. Smaller epidemics also broke out in Spanish and Portuguese Guinea, though of the latter no clear account has been published. Sporadic cases likewise were seen in Gold Coast and Nigeria, while immunity surveys among young children and monkeys indicated that the disease was in fact widely distributed during the years of war. The freedom of the armed Forces from yellow fever must be attributed to the fact that they were very carefully and systematically immunized against the disease. At the same time immunization was also extended to civilian populations in areas where the new knowledge of the

epidemiology of yellow fever indicated that outbreaks might be specially dangerous to the war effort.

The epidemiology of yellow fever in its broad lines is now clear. The fact that the disease is transmitted from man to man by the stegomyia mosquito *Aedes aegypti* is seen to be only part of the picture. Yellow fever both in Africa and South America appears to be primarily an enzootic or in many cases an inapparent infection of monkeys, transmitted from one animal to another by forest-dwelling mosquitoes. Occasionally an infected monkey mosquito may bite a human being, or an infected monkey approaching human habitations may be bitten by a house-haunting *Aedes aegypti*. If the latter mosquito is common in a village a typical *Aedes aegypti* outbreak may follow, provided a high proportion of the population is not already immune.

The role of monkeys in the spread of yellow fever was first suspected by Sir Andrew Balfour² in 1915, but it was not till 1936 that both in South America³ and in Africa⁴ primates were shown to be immune to the disease. Since then monkeys have been found with immune bodies in many countries of Africa. Durrant *et al.*⁵ for instance, have reported that a high percentage of the baboons on the north bank of the Gambia River are immune. As hordes of three to four hundred baboons not infrequently raid the unfortunate Gambian's farm, this monkey may well be responsible for maintaining infection in this area. In Uganda the lowland colobus monkey, *Colobus polykomos vellensis*, is probably the main species involved in the monkey-to-monkey yellow fever cycle in the uninhabited forest areas, while *Cercopithecus nictitans* plays an important part in bringing the virus into close contact with man.⁶ In Barotseland and Northern Bechuanaland, however, no infected monkeys have been found.⁷

In South America the oecological picture differs again. Thus in an endemic area in Brazil the marmoset *Callithrix penicillata* has actually been found infected on four occasions at a time when an epizootic was occurring among these animals.⁸ In Colombia the squirrel monkey, *Saimiri sciureus caquetensis*, is the most susceptible to yellow fever, except in a few areas where its place is taken by the marmoset *Oedipomidas oedipus*.⁹ The evidence that marsupials play a part in maintaining infection is less complete.

It seems that the mosquitoes involved also differ in different areas. Lewis,¹⁰ for instance, divides the Anglo-Egyptian Sudan into a number of oecological zones with differing mosquito faunas. Around Malakal, Kaka, and possibly Tonga, on the direct air line from Alexandria to the Cape, *Taeniorhynchus africanus* appears to be the probable vector, for *Aedes aegypti* has been found there or control for many years, and none has been found there in the surrounding country. Yet yellow fever has undoubtedly occurred in this area in recent years.¹¹ In the Nuba mountains during the great epidemic of 1940 infection was transmitted from man to man probably by *Aedes metallicus*.¹² In Uganda, in the forest region, the most likely vector is the mosquito *Aedes africanus*, whose favoured habitat is in the upper foliage of trees. *Aedes africanus* is a crepuscular or night feeder, and transmission

of the infection to monkeys probably occurs at night when the animals are asleep rather than during the day. In East Africa man is rarely if ever infected in the forest after nightfall. Human infections in Uganda probably result from a secondary cycle in which *Aedes simpsoni* functions as a vector. This mosquito is a plant-axil breeder and is found principally along the edges of forests and about human habitations.¹³ Presumably *A. simpsoni* initially acquires the infection from marauding monkeys, but thereafter the virus may be transmitted from man to man through the medium of this mosquito.

In West Africa, where the extent of tropical rain forest is now somewhat limited, man would seem to be very rarely infected in the forest at night. Infection probably occurs more commonly through infected monkeys raiding farms in the vicinity of villages and thus passing on the infection to *Aedes aegypti*, which exists in most West African villages. In South America the virus, according to Laemmert and his colleagues,¹⁴ crops up in different places by direct extension through the forest zone. The haemagogus mosquito is the principal vector, and as it is a day feeder woodcutters and others who visit the forest are the victims. Very occasionally *Aedes leucocelaenus* may transmit infection.

The whole problem of the epidemiology of yellow fever has been complicated by the fact that virucidal bodies have been found in the sera of certain animals which there is good reason to think have never been infected with the yellow fever virus.¹⁵ In addition to cows and sheep, the sera of certain rodents have been found, both in Africa¹⁶ and in South America,¹⁷ to neutralize the yellow fever virus. Of 1,794 rodents tested in one endemic area in Brazil 449, or 25%, were positive, but, contrary to what would be expected of an acquired specific immunity, the proportion of positive reactors did not increase with age.

A further complication is the finding of virucidal bodies in the blood of certain birds in West Africa,¹⁸ in an area of South Africa⁷ where primates gave negative results, and in Brazil.¹⁴ Of 114 birds examined in Brazil the blood of 3 inactivated virus, in South Africa 2 of 6, and in West Africa 4 of 40. Laemmert and Moussatché,¹⁷ working with laboratory strains of yellow fever virus, have found that it will circulate in the blood stream of birds for several days after injection, but attempts to infect birds by mosquitoes have not been very successful. Elucidation of the origin and nature of these virucidal bodies, which are not found in every specimen but in only a small percentage of certain species of animals and birds, is a matter of considerable importance not only for the epidemiology of yellow fever but for the study of virus diseases in general.

GOLDEN JUBILEE OF R.A.M.C.

This week the R.A.M.C. celebrates the Golden Jubilee its foundation in 1898, when Queen Victoria signed a royal warrant stating: "Our Will and Pleasure is that the officers below the rank of surgeon-major-general serving in Our Army Medical Staff shall be formed into corps, together with the warrant officers, non-commissioned officers, and men of Our Medical Staff Corps; it is Our further Will and Pleasure that the designation 'Medical Staff Corps' shall be abolished, and that the corps formed as above-mentioned shall be styled 'The Royal Army Medical Corps.'" Before the standing Army was raised in 1660 medical men engaged in warfare were the personal attendants of high officers. In that year the few medical officers and orderlies incorporated in the Regular Army wore the uniforms of their regiments, and except for some garrison and general hospitals the medical service was regimental. Apothecaries and a number of lay officers for administration and supply swelled the ranks, but the medical arrangements in the field were often disorderly, though during the Napoleonic wars the sick and wounded received considerably more attention than formerly. Not until 1854 was the Hospital Conveyance Corps formed—solely to evacuate the wounded. It proved to be a failure in the Crimean war, chiefly because it consisted of old and feeble pensioners, and it was incorporated in the Land Transport Corps the following year, thus in effect being a predecessor of that part of the R.A.S.C. that has always co-operated so well with the R.A.M.C. In 1855 the Medical Staff Corps was created by royal warrant; its personnel had neither military titles nor badges of rank, and the sole officer appointed to it (a regimental officer) lived at the depot at Chatham. Naturally enough, this corps was not a success either, and two years later the Royal Will and Pleasure ordered the Army Hospital Corps to be raised forthwith. Its ranks were serjeant-major to private, and were filled chiefly by volunteers from the line and from the Medical Staff Corps. Subsequently some medical and other officers were appointed to it, though their duties were strictly limited. Only inferior medical men presented themselves for service in the Army,¹ and a B.M.A. deputation therefore waited on Lord Lansdowne on Jan. 20, 1898, to advocate the formation of a medical corps with proper ranks. He welcomed the proposals, and the royal warrant appeared on June 23.

It is sometimes said that the Forces' medical services developed as man became more humane. There is little evidence that he has, and in any case there were other more important causes of their growth. Healthy soldiers fight better than ill-nourished and diseased men inspired only by enthusiasm for fighting. Morale is better sustained when men know that they receive early treatment if they are wounded and that they have a high chance of recovery; and the healed can be returned to battle or some other war-winning occupation. Moreover, medicine itself has developed so much in the last 50 years that it is now indispensable for waging war efficiently. A century ago military surgeons could do little to help the sick and wounded

except ease their pain, and any advice they might offer to the fighting men could not have been of much use. Now, even before the modern soldier engages the enemy, he is a highly finished product of medicine's art. Fed on a diet precisely balanced by the dietitians, immunized against typhoid, paratyphoid, tetanus, and smallpox, and possibly cholera, yellow fever, and typhus, dosed with mepacrine, smeared with anti-mosquito cream, the nausea of sea and air travel mitigated by hyoscine hydrobromide, he enters battle in the perfection of health. Physiologists and psychologists have designed his personal equipment, the cockpit of his aeroplane or tank, and his breathing apparatus under water. The R.A.M.C. brings its skill and equipment into the front line beside the fighting soldier; by treating him as soon as possible after he is wounded, and at every stage of his evacuation to the rear areas, it has greatly increased the likelihood of his survival. Fifty years ago a perforating abdominal wound on the battlefield was usually fatal; in the 1914-18 war the overall mortality was 70-75%, and in the recent war about 50%.² Chemotherapy played a large part in reducing the 54% mortality of thoracic wounds in the first world war to 5.7% in the second.²

As medical men we can only be appalled at the tragedy of our art being applied to such ends, at "the expense of spirit in a waste of shame." But when war has been inflicted on us the R.A.M.C. has never ceased to maintain its reputation for skill, courage, and compassion whether in a muddy ditch or a fully equipped base hospital. Its personnel have now to advance its great tradition under the critical eyes of a largely conscripted Army in peacetime, and Queen Elizabeth, their Colonel-in-Chief, who visited the depot at Crookham on June 23, has said in her message to them: "I know that the Royal Army Medical Corps will carry out this new task with the same success as they have accomplished those given to them in their long and distinguished history."

ARTIFICIAL LIMBS

The Ministry of Health has decided that patients in the National Health Service requiring artificial limbs will have to obtain them from the contractors to the Ministry of Pensions. It appears that there are only two firms who have contracts with the Ministry—one for supplying artificial upper limbs and the other for lower limbs. A surgeon who amputates a limb will have to send his patient to a Ministry of Pensions hospital for prescription of the artificial substitute. It is also intended that the patient requiring amputation should have this done at a Ministry of Pensions hospital if possible.

As was stated in the Departmental Report¹ issued in 1945, the Government is entitled to say that limbs the cost of which is met wholly or mainly from State funds should be obtained from their own suppliers. But it was also stated that "no action should be taken by the Government which would have the effect of gradually forcing out of business those firms which do not supply the Government." The Report was, of course, issued at a time when the National Health Service was in embryo, but after July '5 every amputee in the country will have the right to obtain an artificial limb from the Government. The

effect of the decision to grant a monopoly for the supply of limbs, therefore, will be to drive private firms out of business, an effect contrary to the advice of the Ministry of Pensions Committee in 1945. We understand that one well-known firm that has made substantial contributions to the design of artificial limbs has decided to close down its artificial-limb department. The business side of this matter is no concern of the medical profession, but we are concerned with the dangers of a monopoly. As Professor H.J. Seddon points out in a letter to *The Times*,² referring to the work of the Departmental Committee, of which he was a member, "many of us thought that the Ministry contractors had become stuck in a groove—and this indeed proved to be the case." Professor Seddon adds: "It seemed only reasonable that our maimed people were entitled to all the benefits flowing from continued inventiveness and enterprise." If there is to be a Government monopoly of artificial limbs will there be the stimulus to continued improvement of design so essential if the maimed are to be enabled to undertake productive work in the most efficient way? We hope that the Ministry of Health will have second thoughts on this difficult problem, which might well be considered by the British Orthopaedic Association as an organization best qualified to give authoritative advice.

PROFESSOR MAX NEUBURGER

This week sees the end of the long association between this country and a celebrated medical historian, Professor Max Neuburger, who is leaving these shores for the United States, where he will spend his retirement. Max Neuburger was a distinguished neurologist before he became widely known as a medical historian, but it is in the latter role that his scholarship has established for him a permanent place in medical literature. Professor Neuburger was born in Vienna in 1868 and graduated as a doctor of medicine in 1893. Thereafter he held posts in the Rudolfspital and in the Allgemeine Poliklinik in Vienna. He gradually established himself as a painstaking and learned neurologist in his native city. In 1898 he came under the influence of Puschmann, and from then on he devoted much of his leisure to the study of the history of medicine. He became professor extraordinary in 1904, and from 1917 onwards he was Professor of the History of Medicine in the University of Vienna. The Vienna Institute for the History of Medicine, which he founded, remains a permanent memorial to his great work in this field.

During this Viennese period numerous publications showed evidence of Professor Neuburger's industry and scholarship. One of his earliest contributions was on the historical development of the experimental work of Flourens on the brain and spinal cord, and among other important papers which he wrote at that time are those on the early history of antitoxin therapy of the acute infections, and on the Spanish humanist, Luis Vives. One of the standard works on the history of medicine was Puschmann's "Handbook," and in 1902 Neuburger in collaboration with Julius Pagel, of Berlin, edited a new and much improved edition in three large volumes. This co-operative work of a number of authors retains its place as a standard text to this day.

Professor Neuburger was himself at this time engaged in writing a history of medicine, and this work appeared at Stuttgart between 1906 and 1911. The first volume of an English translation was published by the Oxford University Press in 1910 and the first part of the second in 1925, but it was never completed. The book is marked by sound scholarship and a familiarity with the earlier periods of medical history which is now much more rare than it

¹ Artificial Limbs: Report of the Departmental Committee appointed by the Ministry of Pensions. H.M.S.O. 1945. Price 4d.

² *The Times*, June 15, 1948

was. All those who have used this valuable book will appreciate the wealth of information which cannot readily be obtained elsewhere. After the publication of this monumental work Professor Neuburger communicated many other articles to the journals. He also produced monographs on Johann Christian Reil (1913), on Old Vienna medicine (1921), and the standard biography of Hermann Nothnagel (1922).

Soon after the Germans occupied Austria in 1938, Professor Neuburger came to Great Britain, and for the last nine years he has been on the staff of the Wellcome Historical Medical Museum. During these years he has contributed largely to the current literature on the history of medicine, and he has published a book on *British Medicine and the Vienna School* in which he expresses on every page his conviction of the importance of the work done by British physicians and surgeons during the eighteenth and nineteenth centuries, and his gratitude to the country of his adoption. In his more recent papers he has given an account of some great Irish physicians and of the contributions made to British industrial medicine by Charles Turner Thackeray (1948). Now, when he is approaching the advanced age of 80 years, he once again sets out for a home in another land. He will spend his retirement with one of his sons, who is a medical practitioner in Buffalo. Medical historians all over the world, and indeed the medical profession at large, will unite in wishing Professor Neuburger many more years of active work in the specialty which he has so brilliantly adorned and in hoping that in his new home he will find congenial surroundings and new friends to augment the roll of those who have been indebted to him in the past.

VIRUS HEPATITIS WITH A HIGH MORTALITY

Infective hepatitis has long been known as an important disease in military medicine, but it is doubtful if it has ever been such a serious problem as it was in World War II. Both the epidemic disease and the hepatitis associated with the inoculation of blood or blood products caused such a loss of man-power that research was undertaken in several theatres of war in an attempt to solve outstanding aetiological questions. Although no experimental animal susceptible to infection with the responsible viruses has been found, experiments on human volunteers have confirmed a number of epidemiological observations on the incubation period and the possible mode of spread. In the majority of cases the incubation period is between 15 and 35 days. Experiments indicated that the virus may enter the body through the alimentary tract, but many observers have failed to obtain evidence of such a mechanism and consider that infection by the nasopharyngeal route is more likely.

In limited trials injection of the gamma globulin fraction of certain large pools of human plasma appeared to give some protection provided the individuals were inoculated within a week of exposure to infection. With the slender amount of knowledge available, however, attempts to control the disease under battle conditions met with little success.

As a rule this disease is relatively benign; many patients never consult a doctor, and large-scale inoculation of immune globulin would not appear to be warranted. The mortality rate is usually about 0.2. However, from time to time the disease assumes an extremely virulent form. This may be attributable to local conditions such as dietary deficiencies, as in the outbreak among Brazilian soldiers infected with an heterogenic (serum-containing) virus in Brazil, where the fatality rate was 2.4.¹

Among Africans, also, rates of 3.0 and 6.1% have been recorded.² In an investigation of jaundice in pregnant Nixon³ and his co-workers concluded that the severity of the disease when due to virus infection depended on the state of nutrition of the mother. A recent report by Sherlock and Walshe has a bearing on this aspect of the problem.⁴ These workers examined specimens taken at liver biopsy from 21 individuals who had been living about a year on a diet low in protein, and that mainly of vegetable origin. They conclude that a low protein diet and diminished intake of lipotropic compounds alone do not necessarily cause in man the liver necrosis, cirrhosis or fatty changes which have been produced in rats fed on such a diet. In a paper which appeared in the issue of June 5 (p. 1079) Major K. Damodaran describes the liver changes observed in fatal cases of infective hepatitis. He suggests that the decrease in the vitamin content of the blood may be secondary to the disease process rather than an important predisposing factor.

In a recent epidemic of hepatitis in Denmark with a very high mortality rate the disease was confined almost entirely to women at the menopause.⁵ In the fatal cases the illness usually lasted for several months, with the development of chronic hepatitis and ascites. This epidemic occurred after the subsidence of a widespread epidemic of hepatitis with nothing unusual about the age incidence. No explanation of this extraordinary incident has been forthcoming.

During a recent epidemic among Polish troops in Germany, many of whom were receiving parenteral injections of arsenic and bismuth preparations or penicillin for venereal disease, 74 patients were admitted to one hospital.⁶ The mortality rate was 25.6%. The epidemic was attributed to syringe transmission. Possibly the direct inoculation of virus, together with powerful drugs, in individuals already debilitated by another infection may result in a high death rate. One of the fatal cases of acute necrosis described by Damodaran was that of a patient receiving arsenic injections for syphilis.

In these epidemics there have been secondary factors which might have caused the high mortality, but there have recently been at least two outbreaks in which no such obvious reason was present. Stokes and Miller⁷ have described an epidemic of severe infective hepatitis which occurred in Burma in 1945-6, with a mortality rate of 2.0% in South Burma, but only 0.16% in North Burma. The fatality rate increased when the epidemic was waning, and in the majority of the fatal cases death occurred within 30 days of the onset of the disease. There was no evidence of malnutrition, and Stokes and Miller concluded that a specially virulent strain of virus must have been responsible.

The second outbreak was also extremely localized, being confined to the city of Basle and its environs.⁸ Switzerland was involved in the widespread epidemic of 1942-3, but the fatality rate was only 0.6%. There were 244 cases in the city in 1944, 87 in 1945, and 220 in 1946. But in 1946 there were 44 deaths, giving a case fatality rate of 20%. The usual age incidence was reversed—only 20% of the patients being under 30 years of age—and instead of an even distribution among the sexes there were twice as many cases in women. There was a very high fatality rate in the age group 50-70 years. As in Denmark, this epidemic came to an end completely unexplained.

THE PATHOGENESIS OF TUBERCULOSIS

The difference between primary and adult tuberculosis now appears to be much less distinct than was formerly supposed. It used to be thought that primary tuberculosis, with its small pulmonary lesion and gross lymphadenitis, was a disease of children, while phthisis, characterized by a destructive, progressive, usually apical lung lesion and no lymphadenitis, was considered a disease of the adult. It was generally recognized that primary tuberculosis was the result of exogenous infection, but many authorities believed that this rarely occurred in the adult; phthisis, they maintained, was the result of endogenous infection from foci which had remained latent since the disease was acquired in childhood.

Ustvedt¹ in 1946 described clinical studies in Scandinavia which showed that adult primary infection was becoming more common and that the time interval between primary infection and destructive pulmonary tuberculosis was often quite short. In fact phthisis frequently developed directly from the primary infection. More recently Medlar² has approached the problem from the standpoint of a pathologist. Assuming that the lymph glands indicated an active primary infection and calcified glands a healed primary infection, he reported his findings at the necropsy of adults who died from pulmonary tuberculosis. In these he examined the thoracic and abdominal lymph glands macroscopically with great care. Rich³, among others, confirms that the absence of progressive lesions in the regional glands is one of the distinguishing features of adult tuberculosis when they do occur they may exceed microscopic changes. The presence of microscopic caseation therefore strongly suggests a primary infection. In his 100 cases Medlar found that the lymph glands were caseous in 34, calcified in 46, and normal in 6. The incidence of caseation was highest in the younger adults, and in the older group. Thus it would seem that 34% of the cases in the 16 to 64 years, died from a "reinfected" primary infection, and 46% from a "primary" infection. The remaining 20% had typical progressive tuberculosis.

The presence of caseation in the lymph glands in 17 patients out of 100 is in agreement with the older theories of the pathogenesis of tuberculosis. It seems that after the primary infection, the disease must have been a true reinfection in the sense that it behaved like a second primary infection. This is in agreement with the classical studies of the pathogenesis of tuberculosis in reported similar cases. In addition to the caseation in the lymph glands, primary infections—primary lung lesions with no other involvement—in 22 of the patients, and in 21 cases in which neither caseation nor calcification of glands was found may be examples of a condition but even so they defy classification. Was the progressive pulmonary tuberculosis in these patients the result of a progressive incomplete primary infection or a reinfection after an incomplete primary infection had occurred? Tuberculin testing could help to solve this and other problems in the future.

Gloyne⁴ has advocated the repeated tuberculin testing of a series of patients over a long period of time. The epidemiology of tuberculosis varies in different parts of the world, and another tuberculin survey in this country is long overdue.

It is evident that progressive pulmonary tuberculosis in the adult can no longer be placed in a neat, inclusive category labelled "reinfection" or "post-primary" disease. The controversial conceptions of endogenous and exogenous reinfection also cease to have much practical importance. Phthisis can be the result either of reinfection or of progressive primary disease, and in the past far too much emphasis has been placed on reinfection. It now seems certain that progressive primary infection is an important cause of the disease in adults.

EXCHANGE OF INFORMATION

One of the ill effects of war was the isolation of men of science and learning in different countries from each other. Medical men in Europe have felt this isolation acutely, and since 1945 have been almost painfully eager to learn of the medical progress made in Britain and the U.S.A. European doctors have clamoured for British medical books and journals, and many have been done to supply their wants. One of the surest ways of overcoming international antagonisms is to have the best of the course between the professional groups of different countries, and to this end the free interchange of periodicals is an important step.

Between ourselves and Russia there is still a big gap in the exchange of information. To bridge this gap the British Embassy in Moscow decided to give to the State Central Medical Library certain medical journals, including the *British Medical Journal*. A short time ago the Ministry of Foreign Affairs, U.S.S.R., informed the British Embassy in Moscow that the Directorate of the State Central Medical Library had subscribed to British medical journals and was interested in receiving additional copies. The receipt of the journals from the British Embassy was stated to be the desire of the Director of the Supreme Library of the U.S.S.R. on the procedure to be adopted by the Ministry of Foreign Affairs and their officials in their relations with the embassies and officials of foreign States. As with the State Central Medical Library in Moscow, the State Central Medical Library in London can now be approached by foreigners only through the Ministry of Foreign Affairs. From the western point of view this can be completely senseless and appears to be another attempt to keep Russian medical men in ignorance of the achievements of the decadent bourgeoisie. If we are to reach that understanding with Russia which is essential if peace is to prevail, the channels of intellectual communication must be widely opened. But Russia, it must be admitted, seems to be doing its doctrinaire best to put obstacles in the way, and we can only express our sympathy with the unfortunate librarian of the State Central Medical Library in Moscow at having his powers of selection of books and periodicals clipped by the Ministry of Foreign Affairs.

MEDICAL CHARITIES

When the National Health Service starts, a number of medical clubs and associations and benevolent funds will cease to function and will have surplus funds for disposal. They might like to contribute to some of the medical charities that will continue, and we would mention among these in particular the British Medical Association Charities Trust Fund, the Dain Fund, the Sir Charles Hastings Fund, the Royal Medical Benevolent Fund, and Epsom College, which offers scholarships and favourable terms to the sons of medical men.

AN INTERNATIONAL STANDARD FOR STRETCHERS

BY

R. T. WELLS, M.D., F.R.C.S.Ed.

Lieut.-Col., I.M.S., ret.

In the early days of the Geneva Committee for Aid to the Wounded, the historic forerunner of the International Red Cross Committee, its founders had emphasized the importance of the exchange of ideas and of close co-operation with the medical services of the various Powers. The objectives which exercised Henri Dunant, in particular, included improvement in the means of transport of the wounded, the universal adoption of approved methods of treatment, and the institution of a "veritable museum" of military equipment. Again, Dr. Appia, another of the five famous men who founded the Geneva Committee, made two cogent suggestions in this sense: first, that a collection be made of existing literature on medical equipment; and, secondly, that liaison be established between the Committee and the various national medical services.

In the thoughts of these pioneers was the seed which finally germinated when the Permanent International Commission for the Study of Medical Relief was appointed by the International Red Cross Conference of 1925, and provided with library and museum. Liaison between the Commission and the International Congress of Military Medicine and Pharmacology was officially established in 1929. In the meantime a definite proposal for the general adoption of a stretcher of standard dimensions had been made independently by Colonel van Baumberghen at the International Congress of Hygiene held in Berlin in 1907; but this proposal seems to have been followed by no immediate action.

Experience in the Field, 1914-17

During the 1914-18 war the diversity of types of stretcher in use by the various Powers came into distressing prominence. The measurements of French, British, American, and German stretchers differed to such a degree that each stretcher was suited for transport only in an ambulance of corresponding national origin. Thus the wounded had at times to be transferred from one stretcher to another—a process inevitably painful, often dangerous, and, in any case, involving loss of time in the urgent business of collecting the wounded. As General Marotte remarked: "Never have the differences in the standard of equipment been so conspicuous and so prejudicial to the interests of the wounded." Even during hostilities conferences were held, including representatives of both sides, in the endeavour to reach some degree of uniformity in means of transport for the wounded, but with no success.

Development of the Idea

In 1921 the Tenth International Red Cross Conference, the first to be held after the war, met in Geneva and included an exhibition of equipment used by the various national Red Cross Societies. Senator Cirio (Italy), President of the International Relief Union, pleaded for the adoption of a uniform standard of equipment by the different national Red Cross Societies in order to facilitate collaboration in relief operations in the case of civil disasters.

At the Twelfth International Conference, held in Geneva in 1925, an international exhibition of military medical equipment had been organized. The Permanent International Commission on Standardization was appointed and the Institute of Study was founded. The primary task before this Commission was emphasized by the President, Dr. Reverdin, in the words: "It is of the utmost importance for the wounded that the dimensions of all stretchers should permit of their adaptation to every type of carrying fitment, and *vice versa*."

A standard of dimensions recommended by the Commission was adopted by the Red Cross Conference held at the Hague in 1929, subsequently modified by the Brussels Conference in 1930, and finally approved by the Tokio Conference of 1934. This model, however, for one reason or another, failed to win the approval of the various national medical services.

The Commission undertook extensive research on other medical problems of armies in the field, up till their thirteenth and last pre-war session; but, in spite of their momentous labours, the outbreak of the 1939-45 war found their original objective—the adoption of an international standard of stretchers—still unattained.

Civil Defence

Advances in the technique of bombardment from the air had led to the development of special measures of passive defence including the provision of first-aid and ambulance services for the collection of casualties among the civil population. In England this task was undertaken by the specially created Air Raid Precautions Department of the Home Office. For this purpose ambulance transport was formed by stripping the coachwork of selected motor-cars and building on the bare chassis an ambulance body of simple standard design.

The "A.R.P." stretchers were rigid, the poles consisting of cast-iron tubing and the beds of iron-wire mesh. The all-over dimensions of the British Army stretcher were adopted, but the "feet," consisting simply of downward salents on the poles, were too wide for admission to the grooved carrying-fitment of the Army ambulance.

Of the three main types of stretcher in use in England during combined operations—British, American, and A.R.P.—none were mutually interchangeable. Ultimately a simple adaptation of the width of the A.R.P. stretcher-racks permitted the carriage of both American and British Army stretchers in A.R.P. ambulances. An awkward feature of all three types was the length of the rigid poles, which prevented their introduction to most hospital elevators.

Conclusion

Allowing for differences in materials of construction and in details of fitment, it is evident that a stretcher of standard dimensions could meet most, if not all, occasions, both civil and military; indeed, the argument in favour of a universal type applies not only to armies but to civil institutions and voluntary organizations.

The outbreak of the 1939-45 war called a halt to the activities of the Standardization Commission; the contents of their library and museum went into store, but it is hoped that, in view of the first post-war International Red Cross Conference, due to be held in Stockholm next autumn, the Commission will be endowed with a new lease of life and will see its beneficent labours crowned with success.

LADY TATA MEMORIAL TRUST

International Awards for Research in Blood Diseases

The Trustees of the Lady Tata Memorial Fund announce that, on the recommendation of the Scientific Advisory Committee in London, they have made the following awards for research in blood diseases, with special reference to leukaemia, in the academic year beginning Oct. 1, 1948.

Grants for Research Expenses and Assistance.—Dr. Marcel C. Bessis (France), for work in Paris; Dr. Jörgen Bichel (Denmark), for work at Aarhus, Denmark; Dr. Pierre Cazal (France), for work at Montpellier; Dr. Johannes Clemmesen (Denmark), for work in Copenhagen; Dr. Peter A. Gorer (Great Britain), for work in London; Dr. Andrew Kelemen (Hungary), for work at Szeged; Dr. Edith Paterson (Great Britain), for work at Manchester; Prof. Edoardo Storti (Italy), for work at Pavia.

Scholarships (for whole-time or part-time research).—Dr. Simon Iversen (Denmark), for work in Copenhagen; Dr. Claus F. M. Plum (Denmark), for work in Copenhagen; Dr. Guido H. R. Tötterman (Finland), for work in Helsinki.

Mr. R. W. Raven, surgeon to the Royal Cancer Hospital and the Gordon Hospital for Gastro-Intestinal and Rectal Diseases, left Britain on June 12 to lecture to the Roman Surgical Society in Rome. Between June 19 and 29 he is lecturing on behalf of the British Council to the medical schools of Florence, Bologna, Milan, and Turin.

TREATMENT OF DEFICIENCY DISEASES

TABLE II

Factor	Pharmaceutical Preparation Available	Dose	Approximate Cost Per Dose
Vitamin B ₁	Tablets: 1-5 mg. and 25 mg. Ampoules: 1, 2, 5, 10, 25, 50 mg.	10 mg. 10 mg.	s. d. 3 ½
Riboflavin	Tablets: 1, 2, 5 mg.	10 mg.	4
Nicotinic acid	Tablets: 10, 25, 50, 100 mg.	50 mg.	7 ½
Nicotinic amide	Tablets: 50 mg.	50 mg.	1 0
Folic acid	Tablets: 5 mg.	5 mg.	2
Crude liver extract	Ampoules: 1, 2, 5 ml.	25 mg.	6
Pantothenic acid	Tablets: 3, 25 mg.	50,000 I.U.	3
Vitamin A	Cod-liver oil (1,000 I.U./g.) Halibut-liver oil (30,000 I.U./g.) Vitamin A concentrate (50,000 I.U./g.)	50,000 I.U. 50,000 I.U. 50,000 I.U.	2 6
Vitamin D	Tablets: 1, 2, 5 mg. Liquid	10,000 I.U. 10,000 I.U.	3 ½
Vitamin K	Tablets: 2, 10 mg. Ampoules: 5, 10 mg.	1 mg. 1 mg.	less than ½
Vitamin C	Tablets: 5, 10, 25, 50 mg. Ampoules: 50, 100, 500 mg.	500 mg. 100 mg.	3 ½ 2 ½

ACCELERATED PAINLESS LABOUR
LECTURE BY PROF. LOUROS

A lecture, attended by the Greek Minister, was given at the Royal College of Obstetricians and Gynaecologists on June 11 by Dr. N. C. Louros, professor of obstetrics and gynaecology in the University of Athens.

Prof. Louros, who brought the salutations of the Faculty of Medicine of Athens, of which he is dean, said that almost a century had elapsed since John Snow in 1853 tried to obtain obstetric analgesia by administering chloroform to Queen Victoria. From that time onwards repeated efforts had been made in the same direction, but wholly satisfactory results had not been achieved. At regular intervals new methods were announced, but they were not without disadvantages and risks, particularly in the prolongation of labour. Analgesia was a double-edged weapon. It reduced pain, but it had an inhibitory effect on the contraction of the uterus. He held that this inhibitory effect of successful analgesia could be counteracted by the use of utero-constrictor substances. He believed this procedure offered some advantages in that it was applicable from the onset of labour. After many trials he had selected pethidine hydrochloride, a hydrochloride of methyl-phenyl-piperidine-carboxylic-ethyl acid ester, which had a maximum analgesic action; but any drug similar to this might be used provided it was non-toxic and produced a high degree of analgesia.

The effect of a small quantity of pethidine given during dilatation, especially in cases in which some abnormality was present, was minimal, and to be certain of results he combined pethidine with the administration of "thymophysin." The combination of these two drugs, one tending to reduce or abolish pain and the other assuring the continuance of uterine contraction, had proved favourable. As soon as dilatation began, he administered a small quantity of pethidine together with thymophysin. The patient then became somnolent, but reacted perfectly during the stage of expulsion, and slept well during the intervals between contractions. When delivery had been effected the patient usually expressed surprise at the diminution or absence of pain. In addition to freedom from pain a second important result of this drug combination was a considerably reduced and rarely extended over more than three or four hours. For some years he had been in the habit of giving active treatment in cases of premature rupture of the membranes with primary or secondary inertia by using heat in the form of light baths for from ten minutes to half an hour, and these also were of service.

Technique and Results

For the full achievement of painless and accelerated labour some additional measures were indicated—details perhaps, of practical importance. First of all, the patient must adopt the most favourable position for expulsion. A useful manoeuvre was to press strongly with the palms of the hands on the thighs, though before this manoeuvre could be undertaken there should be absolute certainty that dilatation was complete, and the procedure should be carried out only during contraction. This was sometimes desirable during the last phase of expulsion to administer a few drops of ethyl chloride or to give some gas necessary. Pethidine was non-toxic, had no undesirable effect on the child, and no inertia was observed either during or after placental delivery. The procedure he had described, which aimed at achieving an accelerated painless labour, could only give satisfactory results when pethidine and thymophysin were given together and the other procedures he had just mentioned were carried out. This method should be used only by experienced obstetricians.

Prof. Louros added that he could not claim universal success for his method. Moreover, these drugs were expensive and so he had not been able to use them in as many cases as he would have wished. He had applied his method in roughly 600 cases, of which about 450 were normal labours. The analgesic action was complete in some 500 cases out of the 600, incomplete in 75, and had failed altogether in about 25; but even when the analgesia failed, the acceleration of labour, which itself shortened the duration of pain, might be considered a helpful factor. He thought he was justified in saying therefore that in experienced hands this method enabled a considerable contribution to be made towards solving the problem of pain during labour and relieving the strain and exhaustion of a prolonged confinement.

Sir William Gilliat, president of the Royal College, who took the chair, commented on Prof. Louros's mastery of English, which, he said, had been acquired by listening to B.B.C. broadcasts while in a concentration camp during the recent war. The Anglo-Saxons had been pioneers in the relief of pain in obstetrics, and in this field as in others they were glad to have the co-operation of Greek medicine.

SIR ALEXANDER FLEMING IN SPAIN
[FROM A CORRESPONDENT]

Sir Alexander Fleming's visit to the capital of Catalonia as the guest of its municipality has proved a great success. He delivered three lectures, translated immediately from his English into Spanish, on "Some Problems of a Septic Wound," "Lysozyme," and "The Use of Penicillin," besides making several speeches in all of which he expressed his pleasure at the reception he had received. Sir Alexander, who was accompanied by Lady Fleming, was eloquently welcomed by Dr. Garcia Tornel, deputy mayor of Barcelona, and in the presence of many Catalonian physicians in the great hall of the Royal Academy of Medicine he was elected an academician. Another interesting ceremony was Sir Alexander's inauguration of the new research department at the municipal hospital for infectious diseases in a suburb of Barcelona. Before unveiling the black tablet with gold lettering which records in Spanish that this research department was inaugurated by Sir Alexander Fleming on June 5, 1948, he told the assembly of medical men, nurses, and civic dignitaries about his work at St. Mary's Hospital. He wished the rising generation of Spanish scientists all success in their endeavours, and reminded his audience that "the quality of work depends on the quality of the worker." The tablet was veiled by a double curtain of the Spanish and British flags and they fell away to reveal a terra-cotta bust of Sir Alexander.

Among other entertainments arranged by Dr. Trias de Bes and the municipality were a visit to the mountain monastery of Montserrat; a reception at the British Institute, whose director, Mr. Derek Traversi, accompanied the city's guest on many occasions; and an excursion along the tortuous coastal road to the little watering-place of Sitges. There was also a reception by the Rector of the University at which Sir Alexander spoke philosophically about "Success."

to have been originated by the late H. G. Wells, who started the Diabetic Association. Rheumatism, said Lord Horder, was a long-term business; it called for a great amount of research and co-ordination of the available methods of treatment. The British Rheumatic Association would help by encouraging centres for rheumatism at university hospitals, by research work, and by the collection of material at clinics. The Ministry of Health had done something in this matter, and the Minister's support was indicated by the presence of a member of the medical staff of the Ministry, Dr. E. T. Conybeare, at the inaugural meeting and by a letter of appreciation from Sir Wilson Jamieson.

Dr. F. Hernaman-Johnson, chairman of council of the new organization, said that it was commonly supposed that rheumatism was of importance to the middle-aged and elderly, but some of the greatest tragedies of this disease were to be found in young people. Rheumatic fever in children and its effects were treated by the general physician rather than by the specialist in rheumatic diseases, but it should be remembered that rheumatoid arthritis frequently attacked young women, especially young mothers after childbirth, and if not skilfully treated the victim might be crippled for life. Spondylitis often attacked young men. The State provided at great expense for the victims of tuberculosis, but did nothing to avert the tragedies of rheumatism. The new Association would urge public authorities to attack this problem, though it did not believe that everything should be done by the State. The Association itself intended to raise funds to build rest centres.

Col. M. Stoddart-Scott, M.P., vice-chairman of council, presented a report of the initial year of the Association, which, he said, had already 1,000 members. It was intended to establish branches all over the country; one had already been set up at Cardiff, and another would be established at Leeds. Vice-Marshal F. P. Don said that this was an opportune moment for the launching of such an Association, because many big-minded corporations, firms, and persons were now making their contributions from institutions which were going to be financed by the State. There was some risk that the more common forms of disease might monopolize the attention of the State Boards, in spite of the fact that rheumatism caused more sickness and invalidism than any other complaint except tuberculosis.

The Association has a governing council which includes representatives of some forty national organizations connected with medical and allied services, social welfare, and industry. Its immediate programme is the enrolment of sufferers and their friends in an organization strong enough to ensure that their needs will be met by national, regional, and local authorities. The honorary organizer is Mrs. C. Neville-Rolfe, well known for her work over a long period of years for the British Social Hygiene Council. The address of the secretary is 111 Woodville Road, New Barnet, Herts.

On May 31 the Princess Royal visited the Westminster Children's Hospital in Vincent Square, of which she is president. On arrival Her Royal Highness was met by Lord Nathan, chairman of the hospital, and Lady Nathan, with Lord Wigram, president of Westminster Hospital, with which the Children's Hospital is amalgamated. Officials of the hospital, members of the committee, and medical staff were presented, and the royal visitor inspected the deaf-mute clinic, the dining-room and milk kitchen, the Gomer Berry ward, the theatre and out-patient gallery, the casualty and dispensary departments, and the nurses' home, and took tea in the lecture theatre. This hospital, formerly known as the Infants' Hospital, was founded by Sir Robert Mond in 1907. It was severely damaged by a high-explosive bomb in 1940, but was partially restored and reopened as an American military hospital during the war, while its day clinic and other work was carried on in an adjoining building in Vincent Square, and the main nursing staff was transferred to Westminster Hospital. The amalgamation with Westminster Hospital took place in 1946-7, and just over a year ago the hospital was reopened under its present name, with 36 beds for children under 12 years of age. Two additional wards have now been opened, making 52 beds, and as soon as conditions permit the bed capacity will be extended to 140. The out-patient department will open and provide a 24-hours service.

BOARDS OF GOVERNORS OF TEACHING HOSPITALS (LONDON)

The Minister of Health has appointed the following chairmen and members of Boards of Governors of Teaching Hospitals.

The Royal Hospital of St. Bartholomew.—Sir George Aylwen (chairman), who is appointed for the period ending March 31, 1951.

Appointed for the period ending March 31, 1950: Sir Herbert Benjamin Cohen, Bt., O.B.E., T.D.; Sir Henry H. Dale, O.M., G.B.E.; Sydney Limbrey Higgs; Prof. Harold Gordon Jackson; Ernest Tom Neathereop, C.B.E., J.P.; Alexander McLaren Niven, J.P.; Wilfred Shaw; Robert Reginald Johnston Turner, O.B.E.; John Spearman Weatherley.

Appointed for the period ending March 31, 1951: Horace Evans; George Graham; Miss Kathleen Mary Halpin, O.B.E.; Richard Christmas Hammett; Charles Felix Harris; John Basil Hume; The Lord Huntingfield, K.C.M.G.; Henry Knight Eaton Ostle; Mrs. A. Louise Reeve; Alderman Charles Henry Simmons, J.P.

Appointed for the period ending March 31, 1952: Ronald Armstrong-Jones; John Joseph Gillard Bishop; Frederick Cecil Wray Capps; Prof. Ronald Victor Christie; William Malcolm Lingard Escombe, D.S.O.; Lady Ismay; Denis Colquhoun Flowerdew Lowson; A. Maxwell Nelson-Barrett; Prof. James Paterson Ross.

The London Hospital.—Sir John Mann, Bt. (chairman), who is appointed for the period ending March 31, 1951.

Appointed for the period ending March 31, 1950: Horace Denton; Professor B. Ifor Evans; Horace Evans; Miss Elizabeth Farrelly; Douglas William Claridge Northfield; V. C. Ponsonby, M.C.; W. M. Pryor, D.S.O.; H. A. Ray; Ronald William Reid.

Appointed for the period ending March 31, 1951: A. G. Allen; F. T. Baldock, J.P.; Prof. James Dixon Boyd; Walter Russell Brain; Herbert William Butler, M.P., J.P.; W. C. Hale, O.B.E., M.C.; Harry Roy Hobson, D.S.O.; J. Jacobs; Sir Albert Stern, K.B.E., C.M.G.; W. Stone.

Appointed for the period ending March 31, 1952: Hubert Ashton; A. E. Clark-Kennedy; Richard Coppock, C.B.E.; Professor Victor Wilkinson Dix; Eustace Hoare; B. A. Salmon; J. Stanley Thomas, J.P.; Prof. Clifford Wilson.

The Royal Free Hospital.—Sir Hubert Winthrop Young, K.C.M.G., D.S.O. (chairman), who is appointed for the period ending March 31, 1951.

Appointed for the period ending March 31, 1950: Mrs. Florence E. Cayford, J.P.; Prof. Winifred Clara Cullis, C.B.E.; Sir Percy Winn Everett; W. E. Ford; Prof. Mary Frances Lucas Keene; Alderman Mrs. Martin-Smith, M.B.E.; John Douglas McLaggan; Prof. Tom Sydney Moore; Albert Clifford Morson, O.B.E.

Appointed for the period ending March 31, 1951: The Lady Bingham; J. Bruce; Basil Mortimer Lindsay Fynn; Miss Gladys Hill; Theo Jenner Hoskin; Alderman Ernest Alexander Minter; Sir Frank Hillyard Newnes, Bt.; Miss E. M. Scarborough; William Reed Hornby Steer; Mrs. Charity Taylor.

Appointed for the period ending March 31, 1952: Geoffrey Bostock; Gerald Edward Breen, O.B.E.; Alderman Mrs. Ruth Carnegie; Arthur John Gardham; Miss Katherine Georgina Lloyd-Williams; The Hon. Mrs. John Mulholland; The Hon. Peter Montefiore Samuel, M.C.; Clement Edward Shattock; Harry Smith.

University College Hospital.—Sir Harold Augustus Wernher, K.C.V.O., T.D. (chairman), who is appointed for the period ending March 31, 1951.

Appointed for the period ending March 31, 1950: Stuart Jasper Cowell; M. L. Formby; Arky Staveley Gough; Edward Andrew Gregg; J. Hadgraft; Mrs. W. C. Northeott; David Randall Pye, C.B.E.; Alan Shefford; The Rt. Hon. Sir Leslie Orme Wilson, G.C.S.I., G.C.M.G., G.C.I.E., D.S.O.

Appointed for the period ending March 31, 1951: Miss Vera Dart; Neil Hamilton Fairley, C.B.E.; Sir Archibald Montague Henry Gray, C.B.E.; Prof. George Macdonald; Sir Alexander Hyslop Maxwell; George Mitchell; Sir Findlater Stewart, G.C.B., G.C.I.E., C.S.I.; Stephen James Lake Taylor, M.P.; Miss Doris E. Westmacott.

Appointed for the period ending March 31, 1952: Frederick J. Ballard; The Hon. Margaret Bigge; Haydn Davies, M.P.; C. W. Flemming, O.B.E.; Kenneth E. Harris; Prof. Harold Percival Himswoorth; R. J. Kirby; Seymour Cochrane Shanks; Hugh Walter Kingwell Wontner.

The Middlesex Hospital.—The Hon. John Jacob Astor (chairman), who is appointed for the period ending March 31, 1951.

Appointed for the period ending March 31, 1950: Sir Eric Gore-Browne, D.S.O.; Somerville Hastings, M.P.; Lionel Frederick Heald, K.C.; Charles Grafton Izard, O.B.E.; Fred Messer, J.P., M.P.; Walter Bristowe Morison; Simon Whitbread; Maurice Henry Whiting, O.B.E.; Prof. Brian Wellingham Windeyer.

Purdon Martin; P. McHugh; The Countess of Rothes; Julian Taylor, O.B.E.; William Henry Taylor.

Appointed for the period ending March 31, 1951: Donald N. Black; W. Russell Brain; Edward Arnold Carmichael, C.B.E.; The Hon. Mrs. Waley Cohen; Sir Archibald Gray, C.B.E.; Austin Charles Longland, K.C.; Piers Danvers Power.

Appointed for the period ending March 31, 1952: Denis Hubert Brinton; Miss Kathleen Cooper-Abbs; Prof. D. Hughes-Parry; The Lord Rayleigh; John Kenyon Vaughan-Morgan; Francis Martin Rouse Walshe, O.B.E.

The Royal National Throat, Nose, and Ear Hospital.—Ernest Edward Taylor (chairman), who is appointed for the period ending March 31, 1951.

Appointed for the period ending March 31, 1950: A. G. Farr; Lewis Davis Lewis; Frank Cunliffe Ormerod; Joseph Reginald Rosselli; Mrs. Mabel Rye.

Appointed for the period ending March 31, 1951: Nehemiah Asherson; Ferdinand Robert Eiloart; Gilbert Haywood Howells; W. Humphrey; William Stewart McKenzie; A. W. Scott.

Appointed for the period ending March 31, 1952: Samuel Arthur Beards; Chapel Gill-Carey; Frederic Noel Hornsby; Thomas Henry Lawley; Mrs. Obre Alsager MacIver; Mrs. Clare Turquet.

The Moorfields Westminster and Central Eye Hospital.—The Lord Luke, J.P. (chairman), who is appointed for the period ending March 31, 1951.

Appointed for the period ending March 31, 1950: N. E. Behrens; John Douglas Magor Cardell; Mrs. Elsie Franks; Frank William Law; Sir Harold Spencer Morris, M.B.E., K.C.; Miss Spenser-Wilkinson; Sir John Stainton, K.B.E., K.C.

Appointed for the period ending March 31, 1951: Edward Philip Carter, O.B.E.; F. le Gros Clark; Eric Walter Hall, J.P.; Mrs. Annie Louisa Hollingsworth, J.P.; Swithin Pinder Meadows; George Parker-Jervis; The Earl of Rothes.

Appointed for the period ending March 31, 1952: Jonathan Backhouse; Robert Cecil Davenport; Sir Stewart Duke-Elder, K.C.V.O.; The Hon. Arthur Gore; Francis William Lascelles; Thomas Keith Lyle; Alderman Charles H. Simmons.

The Bethlem and Maudsley Hospitals.—Gerald Edward Coke (chairman), who is appointed for the period ending March 31, 1951.

Appointed for the period ending March 31, 1950: W. J. Bourne; Mrs. Eva Marian Hubback, J.P.; Prof. Aubrey Julian Lewis; Alderman Thomas Edward Morris, J.P.; T. A. Munro; Prof. Samuel Nevill; Alderman Sir Frederick Michael Wells; George Percival Wright.

Appointed for the period ending March 31, 1951: M. Critchley; Charles Gordon Dickson; Miss Dorothy F. Sutherland Gill; Mrs. H. Girling, O.B.E., J.P.; W. G. H. Luckett, J.P.; Mrs. Norah C. Runge, O.B.E.; Ernest Charles Sherwood.

Appointed for the period ending March 31, 1952: Prof. R. V. Christie; John Gerard Hamilton; William Gordon Masfield, J.P.; Prof. J. McMichael; J. F. Murphy; Dr. Doris Odum; Mrs. Mary Ormerod; Gerald Eustace Howell Palmer.

St. John's Hospital for Diseases of the Skin.—J. A. M. Ellison-Macartney (chairman), who is appointed for the period ending March 31, 1951.

Appointed for the period ending March 31, 1950: Francis Ray Bettley; Sir Archibald Gray, C.B.E.; Hal Gutteridge; Humphrey Whitbread.

Appointed for the period ending March 31, 1951: A. Franklin; Sir Samuel Gluckstein; Gordon Barret Mitchell-Heggs, O.B.E.; John Bryan Poynder; Seymour Cochrane Shanks.

Appointed for the period ending March 31, 1952: Henry Corsi; Arthur Herbert Montgomery; Edward Snowdon, J.P.; John Edwin MacKenochie Wigley.

The Hospitals for Diseases of the Chest.—Sir Robert Arthur Young, C.B.E. (chairman), who is appointed for the period ending March 31, 1951.

Appointed for the period ending March 31, 1950: Alderman Albert Edward Allaway, J.P.; The Lord Blackford; Mrs. M. G. Burton; John Harold Cooke; Sir Bennett Hance, K.C.I.E., O.B.E.; Sir Henry Pelham Wentworth Macnaghten; A. J. Newman; Sir Hugh Stephenson Turnbull, K.C.V.O., K.B.E.; Frederick Hugh Young, O.B.E.

Appointed for the period ending March 31, 1951: R. C. Brock; Mrs. Ann Bromley, J.P.; Mrs. Sarah Candy; Sir John Little Gilman, Bt.; Vincent Alpe Grantham; John Clifford Hoyle; J. L. Hinton; Clarence Rutter; Sir Harold Scott, K.C.M.G.; Vernon Cecil Thompson.

Appointed for the period ending March 31, 1952: The Lord Devonshire; The Hon. Lord Glyn, O.B.E.; Frederick Roland George Hoff; Leslie Burnett Preece; J. G. Scadding; Joseph Smart; Ben Smith; William Stafford; Clement Price Thomas.

The Royal National Orthopaedic Hospital.—Louis Fleischmann, C.B.E. (chairman), who is appointed for the period ending March 31, 1951.

Appointed for the period ending March 31, 1950: E. P. Brockman; Fletcher Bremner Coates; A. T. Fripp; Howard Kerr, C.M.G. C.V.O., O.B.E.; William Nichols, J.P.

Appointed for the period ending March 31, 1951: Sir Henry Robert Kincaid Floyd, Bt., C.B., C.B.E.; F. Campbell Golding; Prof. George Perkins, M.C.; H. C. Willig; Miss M. Joan Wood.

Appointed for the period ending March 31, 1952: Harold Jackson Burrows; R. Y. Paton; Stanley Graham Rowlandson, M.B.E.; Harold Sutcliffe, M.P.; The Lady Wakehurst.

The National Heart Hospital.—Milton Victor Ely (chairman), who is appointed for the period ending March 31, 1951.

Appointed for the period ending March 31, 1950: R. C. Brock; John Maurice Campbell, O.B.E.; The Earl of Cromer, G.C.B. G.C.I.E., G.C.V.O.; J. Simons; Leslie Hamilton Watts.

Appointed for the period ending March 31, 1951: John Mar' Freeman Cohen; Thomas Forrest Cotton; Sir Francis Fraser; J. M. Oakey, M.C., J.P.; Basil T. Parsons-Smith.

Appointed for the period ending March 31, 1952: Sir William Arbuthnot Lane, Bt.; Sir John Parkinson; P. H. Wood, O.B.E.

St. Peter's and St. Paul's Hospitals.—Laurence E. D. Bevan (chairman), who is appointed for the period ending March 31, 1951.

Appointed for the period ending March 31, 1950: A. W. Badenoch; Alfred Ridley Martin; Claude Harry Mills; Sir Hewitt Skinner, Bt.; Hubert Martin Tobin; R. Ogier Ward, D.S.O., O.B.E., M.C.

Appointed for the period ending March 31, 1951: Arthur McNeil Farquhar; Sir Bertram Galer, J.P.; A. R. C. Higham; I. G. Mitchell-Innes; G. Williams; Horace Powell Winsbury-White.

Appointed for the period ending March 31, 1952: F. J. F. Barrington; A. R. G. Hudson, O.B.E.; E. D. Jefferiss Mathews, O.B.E.; The Rev. Ernest Reginald Moore; Albert Clifford Morson, O.B.E.; Miss Rosina Whyatt.

The Royal Cancer Hospital.—Sir Giffard Le Q. Martel, K.C.B., K.B.E., D.S.O., M.C. (chairman), who is appointed for the period ending March 31, 1951.

Appointed for the period ending March 31, 1950: A. Lawrence Abel; Alderman Albert Edward Allaway; Prof. R. G. D. Allen, O.B.E.; D. E. W. Gibb; Sir Kenneth Wigram, G.C.B., C.S.I., C.B.E., D.S.O.; W. G. Wilsher; F. Griffiths Woollard, J.P.

Appointed for the period ending March 31, 1951: Prof. Ian Aird; Alfred Chester Beatty; P. E. Thompson Hancock; Gordon L. Jacob; Prof. W. V. Mayneord; Mrs. Noel Patrick; G. C. Stanley; C. M. Vallentin, M.C.

Appointed for the period ending March 31, 1952: The Lord Ashecombe; G. Koch de Gooreynd, O.B.E.; Prof. Alexander Haddow; John B. Hunter, C.B.E., M.C.; Septimus Leonard Lyons; Mrs. Murray-Graham; Prof. D. W. Smithers.

Queen Charlotte's and Chelsea Hospitals.—Sir Frederick Minter (chairman), who is appointed for the period ending March 31, 1951.

Appointed for the period ending March 31, 1950: Frank Cook; The Hon. Mrs. Eliot Hodgkin; Mrs. A. Margaret King, J.P.; Desmond Reid; Mrs. Norah C. Runge, O.B.E.; J. Montagu Wyatt; Prof. James Young, D.S.O.

Appointed for the period ending March 31, 1951: H. G. E. Arthur; Miss Joan Bourne; Aubrey Goodwin, O.B.E.; The Viscountess Jowitt; E. Musgrove; Charles Newman; Alexander McLaren Niven; Lady Oglivie; Goodman Whiffen.

Appointed for the period ending March 31, 1952: A. C. H. Bell; The Lord Bingham; Alderman Mrs. Olive Alice Florence Davis; A. J. Espley, O.B.E.; The Hon. Mrs. Angela Murray; J. Senior; Charles Lionel Woolveridge.

The Eastman Dental Clinic.—Sir Frank Hillyard Newnes, Bt. (chairman), who is appointed for the period ending March 31, 1951.

Appointed for the period ending March 31, 1950: Miss Rosamond Caseley; Sir Percy Winn Everett; Prof. W. E. Herbert; Miss Eileen Norah Morton; W. H. Stevenson.

Appointed for the period ending March 31, 1951: Clarence Endicott; William Kelsey Fry, C.B.E., M.C.; B. M. Lindsay Fynn; A. C. McLeod; G. Meekoms; William Ritchie Young.

Appointed for the period ending March 31, 1952: Frederick J. Ballard; Alan Clark Deverell; Mrs. Dorothy M. Holman; Arthur Douglas Page; The Hon. Peter Montefiore Samuel, M.C.

Mr. John Edwards, Parliamentary Secretary to the Ministry of Health, opening the London County Council's Elderwood Home for aged people at Norwood, Surrey, on May 12, spoke of the national assistance scheme due to come into force on July 5 as rounding off a comprehensive plan of social service. The National Assistance Bill, he said, should help in finding out what the old folks really needed. The general opinion was that from 30 to 40 persons made a better unit than 60 or 70. The L.C.C. were experimenting to decide the most satisfactory size. They had already many rest homes of 30 to 40 or even smaller, and some of 80 to 100, and indeed larger institutions, which some residents preferred.

Correspondence

B.C.G. Vaccination

It seems to me that my article under which Prof. Wallgren, at the Conference of Physicians last September I did not attempt to diminish the value of B.C.G. vaccination. I made it clear at the beginning that I was deliberately marshalling the evidence against it, and at the end that the conclusions I drew were solely in relation to its probable effect on tuberculosis *in this country*. I wanted to show that no entirely satisfactory investigations on the efficacy of B.C.G. had yet been carried out, and that, because of the differing epidemiology of tuberculosis in different countries, conclusions drawn in one part of the world were not necessarily applicable to another. I pleaded for a properly conducted investigation into the value of B.C.G. vaccination under British conditions, which, as readers of Prof. Wallgren's article will realize, are very different from those in Sweden. I think, in fact, for no more than the International Conference in London has asked to do in the United States. I do not obtain it, and we shall be for the use of B.C.G. in the United States. I

...different from those in Sweden. If we do not obtain this information now, we shall probably never obtain it, and we shall be forced by public opinion to adopt the use of B.C.G. indiscriminately. If, on the other hand, we do succeed in carrying out an investigation under "scientific and unimpeachable conditions"—and there seems to be some hope of this being realized—I am ready to assure Prof. Wallgren that I shall abide by the results.—I am, etc.,
London, S.W. 1.

Some Dust Diseases of the Lungs

Some Dust Diseases of the Lungs

Sir - In your leading article, "Some Dust Diseases of the Lungs" (June 5, p. 1087), in which you comment on my Goulstonian Lectures, there are some misquotations which may give rise to misunderstanding. You say, "In 1947 men were certified in South Wales at the rate of 100 a week, and certification has risen in all the other coalfields of Great Britain, the provisional figures for 1947 showing a rise of about 1,000 in that year." In fact, it was in 1945 that this high rate of certification was reached in South Wales and in 1947 it had fallen to about 60 a week. In the rest of Great Britain provisional figures show a rise to about 1,000 not of about 1,000 in 1947. Later on you say that "high dust concentration is due in the anthracite mines mainly to poor ventilation." This should read "high dust concentration was due in the anthracite mines mainly to poor ventilation." In fact, improvement of dust conditions in the anthracite mines has been one of the outstanding achievements in dust suppression in recent years, and ventilation is in general very good in these mines to-day. I am, etc.,

Effect on mortality

Survival in Pulmonary Tuberculosis

BRITISH
MEDICAL JOURNAL

minor errors, and mainly to plead for more
search into this important subject.
My attempt to assess the value of pneumothorax therapy
based on the fate of nearly 700 cases compared with that of
more than 3,000 cases treated by conservative methods only,
was not universally popular, as the results were less favourable
to collapse therapy than many anticipated and than some felt
was borne out by their own experience. Possibly it was in-
sufficiently realized that the cases investigated were treated
during the decade 1921-30, and, so far as collapse therapy was
concerned, naturally included in those early years a high pro-
portion of cases that to-day would be either abandoned early as
unsuitable for pneumothorax or reinforced or replaced by
other collapse measures. Nevertheless, a glance again at my
conclusions in 1936 shows that even now they are not altogether
out of accord with clinical experience. May I quote the
following :
"Incomplete collapse obtained by means of
pneumothorax therapy may not only be un-
continued,"

"Incomplete collapse obtained by means of artificial pneumothorax therapy, may not only be unavailing in producing quiescence, it may actually prove an added source of danger to the patient if continued."

"Incomplete-collapse cases, and those with pockets of indifferent results and, forming 60% of the whole, are the general level of the results."

"Complete-collapse cases, forming 40% of the whole, are the total, showing a 60% success rate."

“Complete-collapse cases and those with pockets only yield indifferent results and, forming 60% of the whole, they drag down the general level of the results.”

“Complete-collapse cases on the other hand, accounting for 40% of the total, show more encouraging results. Out of 208 such cases investigated in detail 65.9% of the patients were alive after three years, while when the disease was strictly unilateral the percentage survival rose to 77.4.” Furthermore it was recorded that in the complete-collapse cases who were sputum-negative the charge from residential treatment no less than 50% were alive after three years.”

Clearly what

Clearly what is needed to-day is for a more recently treated group of patients to be followed up and analysed in a similar fashion. Accurate statistical follow-up work in tuberculosis is of immense importance. No one realized this more than myself when I was largely responsible for drastically curtailing the L.C.C. tuberculosis statistical work in September, 1939. It is very easy to stop work of this sort. How difficult it is to get it going again—but how necessary! Possibly it has not been reasonable to expect the L.C.C. to start this invaluable and meticulous work again in view of the impending dissolution of its hospital arrangements. May I appeal to Regional Boards to have regard to the work of their predecessors and, while cutting out ruthlessly any dead wood that may be found, to carry on and enlarge all those arrangements and schemes that were so well founded?

A large Region may find that it is spending one million pounds annually on tuberculosis. Is it too much? I am sure it is not. I am sure, say 10% of that sum, say 100,000 pounds, would be well spent in following up and analysing a more recently treated group of patients to be followed up and analysed in a similar fashion. Accurate statistical follow-up work in tuberculosis is of immense importance. No one realized this more than myself when I was largely responsible for drastically curtailing the L.C.C. tuberculosis statistical work in September, 1939. It is very easy to stop work of this sort. How difficult it is to get it going again—but how necessary! Possibly it has not been reasonable to expect the L.C.C. to start this invaluable and meticulous work again in view of the impending dissolution of its hospital arrangements. May I appeal to Regional Boards to have regard to the work of their predecessors and, while cutting out ruthlessly any dead wood that may be found, to carry on and enlarge all those arrangements and schemes that were so well founded?

one million pounds annually on its arrangements for tuberculosis. Is it too much to ask that a small proportion of this sum, say 1%, should be devoted to an attempt to ascertain what are the results of this vast expenditure?—I am, etc.,

Coronary Artery Disease and Hypercholesteræmie
 R.—Drs. E. Sherwood Jones and
 (37) draw attention
 cholesteræmie

SIR,—Drs. E. Sherwood Jones and P. W. Robertson (June 12, p. 1137) draw attention to the question of the relationship of hypercholesteræmic xanthomatosis to arterial atheroma. Such a relationship was especially discussed by the Russian pathologist, S. S. Chalatow, in his German monograph, *Cutaneous Xanthoma and Xanthomatosis* (London, 1924, p. 14). I illustrated the question by the history of a London surgeon with whom I was acquainted. In 1902, at the age of 41 years, he had tuberous xanthoma of both elbows. About seven years later he began to suffer from intermittent claudication of both lower limbs, at first slight but gradually increasing in severity. Intermittent claudication continued till his death in 1909. At post-mortem examination proved that it was due to atheroma (atherosclerosis) of the arteries of the lower limbs.

A striking illustration of the association of xanthomatosis of tendons and tendon sheaths with cardiovascular disease (angina pectoris) in a woman aged 60 years, with blood-serum

NEW TREATMENT FOR ASTHMA

Relatively free from the undesirable cardiovascular and other side-effects of adrenaline injections, 'Neo-Epine'—a recently-developed homologue of adrenaline, possesses marked advantages in the treatment of bronchial asthma. It may be given sublingually or by oral spray. The drug has been found to be an effective substitute for adrenaline. Superior to ephedrine, it does not cause sleeplessness.

'NEO-EPINE'

2,6-DIPICOLATE ADRENALINE SULPHATE

Liver at meal times

Proteolysed Liver A&H is prepared by a process which eliminates the nauseating taste of raw liver. Its palatability has been further improved by its presentation in a paste form. It may be readily incorporated in the normal diet by its inclusion in soups or on toast, bread or dry biscuits.

In pernicious anaemia and other megalocytic anemias proteolysed liver has proved effective in cases which have failed to respond to extracts of liver in general use.

Prevent Discomfort

IN HAY FEVER AND SUMMER COLDS

To the hay-fever victim the use of 'Benzedrine' Inhaler may make all the difference between weeks of acute misery and weeks of comparative comfort. Its vapour diffuses throughout the entire nasal cavity and is strikingly effective in reducing the intense congestion which makes allergic rhinitis so distressing.

Head colds are particularly annoying during the summer. 'Benzedrine' Inhaler helps to cut them short and provides welcome symptomatic relief.

Each tube is packed with Amphetamine (B.P.) 325 mgm., Oil of Lavender 97 mgm., Menthol 32 mgm.

BENZEDRINE[®]

cholesterol estimated at 400 mg. per 100 ml., was demonstrated by Dr. H. J. Anderson in 1943 (*Proc. R. Soc. Med.*, 36, 179). Effort angina was first complained of at the age of 52. A sister was known to have had similar "nodules" and angina of effort. There may also be a connexion between arterial atheroma and gall-bladder stones, especially solitary cholesterol stones (D. M. B. Gross, *J. Path. Bact.*, 1929, 32, 503). This would serve to illustrate the whole subject of the occasional association of different types of local or systemic errors of lipid (notably cholesterol) metabolism.

A man with hypercholesterolaemic xanthomatosis told me that a brother of his had recovered from similar lumps on his elbows without medical treatment; but I understood that that brother had recently had to have one leg amputated for what seemed to be ischaemic gangrene—very likely connected with atheromatous disease.—I am, etc.,

F. PARKES WEBER.

Intestinal Lesions in Hypertension

SIR.—Dr. George J. Cunningham (June 5, p. 1075) has described the morbid anatomy of intestinal lesions due to malignant hypertension. In the past two years I have had three cases showing the clinical counterpart of this condition, which is not uncommon.

Case I was a woman of 37 with a B.P. of 280/170. There were marked retinal changes but no albuminuria. She was struck down one day by severe epigastric pain. This made her roll about in agony and she was so ill she could not attract help from her neighbours. Her attack lasted for four hours and went as suddenly as it came without any treatment. She had a similar attack 18 months later, and the pain was abated by morphine. I saw her after her first attack. The pain was not a colic. There was no evidence of either gall-stones or coronary thrombosis, and the physician who saw her a week later agreed with my diagnosis of "visceral angina." Vaso-spasm can occur in any part of the body and be accompanied by excruciating pain. The second case was similar in character, the pain being referred to the right femoral region. In the third case the pain was in the lumbar region.

In each case there was severe pain not fitting into any usual clinical picture. Each case had a marked hypertension. Morphine relieved the symptoms, which did not recur immediately. Two cases have had recurrent attacks several months after the first. The pain is so severe as to make it a first-class medical emergency. Amyl nitrite had no dramatic effect on the pain, although it appeared to give some relief while the morphine was doing its work.—I am, etc.

Leicester.

C. A. H. WATTS

The Spread of Q Fever

SIR.—Your annotation (June 12, p. 1155) prompts me to add Iraq to the list of countries in which Q fever has been found.

In May, 1945, a British sergeant serving in that country fell out of sorts for a few days and thought he was developing a "cold." This did not take the usual course, instead he lost appetite and had intense headache.

He was admitted to hospital with the provisional diagnosis of typhoid or typhus. Mental disturbance, familiar in typhus but which I have not seen recorded in Q fever, became prominent. He was a "difficult" patient, unwilling to take food or sleep and not fully aware of what he was doing. Later he became weaker, confused, and his talk became irrational. The severe headache continued. Subsequently he had no recollection of being taken to hospital or of events for the first nine days of his stay there.

In addition to his mental symptoms, a condition of his circulatory system gave cause for alarm. His blood pressure fell markedly and his pulse was irregular. This was associated with missed heart beats and accompanied by oedema of the ankles. Congestion at the bases of his lungs was revealed by percussion and auscultation. No x-ray examination was done.

Fever was high during his first eight days in hospital. His maximum temperature on the day of admission was 101.5° F. (38.6° C.); this rose to 104° F. (40.2° C.) on the fourth, fifth, and sixth days in hospital. On the ninth day in hospital and twelfth day of illness it fell to near normal.

Twenty-five days after entering hospital he returned home very weak and having lost much weight. The best way to hasten his convalescence appeared to be to get him out of the heat of Iraq, so, as soon as he was fit to travel, which was two weeks after he

left hospital and six weeks after the onset of illness, he was taken by air to England. He was still weak, had difficulty in accommodating and occasional double vision, and it was not till two months later that he felt fit to journey by himself to Canada to join his family.

Complete Widal and Weil-Felix reactions carried out during his illness gave negative results, as did blood culture. It was not till he arrived in Canada that a retrospective diagnosis of Q fever was made on a sample of serum sent to Dr. Norman H. Topping, of the National Institute of Health, U.S. Public Health Service, who reported positive complement fixation to an end titre of 1:1,024 with Q fever antigen.

The source of infection is unknown. There was no contact with cattle, but seven days before the onset of his own illness the patient examined an Iraqi soldier severely ill with an undiagnosed febrile condition. While doing so he had a distinct sensation of an insect crawling on his knee (he was wearing shorts at the time).

During the six months I remained in Iraq I looked for further cases of Q fever both by testing sera from suspects against an agglutinating antigen kindly supplied by Dr. F. M. Burrett and by sending sera to Dr. Norman H. Topping. No more were found, but I cannot believe the case now reported to be unique. Obscure febrile illnesses are common in Iraq and some may well prove to be Q fever.—I am, etc.,

University of Sheffield.

C. P. BEATTIE.

Pain in Childbirth

SIR.—I read with interest the quotation from *The Soul of a White Ant* which appeared in Dr. J. A. Hadfield's letter (June 12, p. 1155). I do agree that scientific investigation of the matter of pain and anaesthetics in childbirth is called for. Eugene Marais's hypothesis assumes that the half-wild Kaffir buck did indeed suffer pain in labour. Can he disprove that the administration of anaesthetic relieved them, not of pain, but of the satisfaction of completing a natural function? I have known many human mothers who, having been anaesthetized during labour, said afterwards that they found it hard to believe that the baby was theirs, or that they had really had a baby. What chance then for a half-wild Kaffir buck?

The difficulty of assessing the intensity of pain, particularly in animals, is almost insurmountable. During labour my pulse rate increased and I perspired, but I was in no more pain than when I lift the end of a heavy sideboard at spring-cleaning time. Since reading Dr. Grantly Dick Read's *Revelation of Childbirth* (which I commend to Eugene Marais and to Dr. Hadfield) I gave birth to a daughter and later to a son, in each case without pain, though at the first confinement a kindly G.P. thought I was suffering and I was very briefly anaesthetized, but not until after the head was born. My son was born before the doctor arrived. It was a natural and painless labour such as a half-wild Kaffir buck might be expected to enjoy. As he was born—and ever since—I loved him. I submit that if mother love is brought about by a release of hormones—and it seems to me to be very likely—then it is the completion of normal, painless labour, and awareness of bringing forth a child, that are the stimuli.—I am, etc.,

York.

GWENDOLINE ROWNTREE.

SIR.—Dr. J. A. Hadfield (June 12, p. 1155) suggests that, as pain in childbirth is necessary for the development of the maternal instinct in animals, anaesthesia during labour may inhibit the development of this instinct in women. It may be true that the stimulus of pain is necessary in animals, but before we deprive women of the great benefit of painless labour it is necessary to assess the value of this "maternal instinct" which would be so dearly bought.

In the first place, are instincts necessarily good? They are essential to the maintenance of life among animals, but the whole progress of man is a struggle to tame and subliminate his instincts, and where possible to substitute reason for instinctive reaction. Even if we were to accept the necessity for reliance on such reactions, we should hardly try to emulate the animals. Consider the duration of maternal feeling in a bitch, a cat, or a vixen: after a few weeks of lactation the young ones are more and more neglected, and soon the mother is unable even to recognize her offspring. If this is the "maternal instinct" which women are supposed to lose by avoiding the pains of labour, I do not think that the human race will be very much worse off without it.

A human being is more than a bundle of reflexes and does not rely on instinct as a guide to behaviour. If instinct ruled, most children would be illegitimate, as there is no such thing as a natural "paternal instinct." The love of a father for his children is highly conditioned, and in the form in which it is seen to-day it is a relatively modern development, the father having become an important part of the human family only in the last few thousand years. I would suggest that it is the indulgence of the so-called "maternal instinct" which breaks up many homes and upsets the proper development of many children to-day. I can hardly believe that the lack of anaesthesia in labour produces this distortion of mother-love, but if it were so it would be a very strong argument in favour of anaesthesia for all mothers.

It is always dangerous to apply the findings in animal experiments to human beings, even in those physical realms in which the lower animals most resemble man, but here we are asked to accept that the human mind requires the stimulus of pain to produce an attitude and an emotional state—the feeling of a woman for her child—which is not in any way comparable with an animal instinct but is made up of tradition, social sense, and a desire for immortality. A woman's love for her child grows with the months and the years; an animal's diminishes rapidly, and disappears completely as soon as its offspring are able to live a separate existence. Pain in labour may well be a necessary stimulus for animals, but in human beings I suggest that it is superfluous and atavistic, resembling the vermiform appendix, and if it can be obliterated by the safe use of anaesthesia that is but one more proof of man's ability to master his environments and reach up to Heaven.—I am, etc.,

Col hester

MARGARET PUXON.

SIR.—Dr. J. A. Hadfield's letter (June 12, p. 1155) touches many controversial aspects of the pain of childbirth. It is not possible to reply adequately to his suggestions and contentions, for neither space nor time is available. The observations and deductions of a clinical obstetrician upon this matter probably differ in perspective from those of the academic psychiatrist and may therefore be of assistance to him in his research. The biological purpose of pain is protective. The individual does not demand protection in an uncomplicated physiological function. Pain has no biological value in normal labour, because it is not present. Pain in labour is a pathological, not a physiological, phenomenon.

Eugene Marais's experiments with Kaffir buck (whether or not his deductions are accurate) are not applicable to women. He writes: "Where pain is negligible, mother love and care are feeble. Where pain is absent, there is absolutely no mother love." If in ten years Marais has found no single exception to this rule in animals, may I say that in thirty years I have never found it to be true of the human mother. Moreover, it is not infrequently recorded that the mother-child relationship is disturbed by the resentment of the mother to her child because of the agony of her ill-conducted labour. Many thousands of women have their babies without anaesthesia or physical pain, and the number is rapidly increasing. They are taught how to avoid the pain of childbirth. They are the conscious witnesses of their own satisfying achievement; they know the profound emotional experience of motherhood accomplished without pain but with joy. Do they by this means destroy the "maternal instinct important for the individual and social psychology"?

It is not pain in labour which "unlocks the door of mother love." Anaesthesia of itself does not inhibit the maternal instinct. When a child is born, the sight of it, the sound of it, and the touch of it open up the floodgates of mother love, which remain open for all time. Through each of the special senses an impression is indelibly imprinted upon the mind, and each impression is the foundation upon which, by sight, sound, and touch, the love of a mother is intensified and matured with the years. Upon the integrity of these processes the psychology and philosophy of parenthood develop, and the depressions from their unselfish purpose lead on directly or indirectly to every social evil.

To-day the pain of labour can almost entirely be avoided in 80% to 95% of normal births. It must be obliterated by other means when it cannot be avoided. In human society a woman who is asked about when her baby is born is usually willing to accept that the child ascribed to her is hers, although many have an unpleasant sense of apprehension but an error might have been made. The general desire for a child, through faith in the rightness of her instincts, overrules the limitations of the unnatural birth, and the pain is established with the return to consciousness; but we do not know of any animal tendency comparable to that of the natural human mother in the highly developed sense of smell of the

newborn, as well as the other sensual impressions, is destroyed by anaesthesia. There is no social conscience or custom to establish the identity of their young. The elements of instinctive possessiveness have been blotted out, and so she disowns, because the natural link to ownership is absent.

It is not the pain but the perfection of birth which liberates maternal instinct when the young are born. Some of us who have been amongst animals from our earliest childhood, known their habits, and closely studied their behaviour are unwilling to accept the statement that all animals suffer in natural parturition. Physical effort and emotional variation within the normal may easily be mistaken for pain unless signs, symptoms, and reactions are carefully investigated and understood.

And finally it is regrettable that the already sordid view of child birth that science has allowed to persist should be accentuated by an authority of Dr. Hadfield's standing. Pain, hypnosis, masochism: are tags upon which the casual reader hangs his ultimate impressions of a publication. Has no one in our profession the courage to state the truth that so many women are fully aware of? Upon it the greatest and most wonderful of all natural functions. Upon it the human race depends, not only for existence, but for its progression to an ultimate purpose.

The health, sociology, and philosophy of the people stand simply and firmly upon the birth of a child and the love of a mother. No branch of our science holds greater potentialities or has better opportunities for service to humanity. We should be careful, therefore, not to make unguarded statements or even suggestions which may deflect the public mind from the truth, and anything concerning childbirth is rightly considered by the Press to be of interest to the community. The pain of childbirth must be avoided or overcome, for no woman should be allowed to suffer when her baby is born. When it is discussed let us emphasize its elimination rather than suggest its necessity. There is still much to learn, but realistic approach is safer than speculative, and practical experience is more profitable than philandering with pansophism. There are still beautiful things in life, and whether we are politicians, psychiatrists, or gynaecologists we have no right to distort them or withhold them from the public, of whom we are the servants.—I am, etc.,

London, W.1.

GRANTLY DICK READ.

SIR,—Despite the risk of entering into discussion with a psychologist I really must join issue with Dr. J. A. Hadfield when he resurrects (June 12, p. 1155) the archaic suggestion that there might be any "diminution of maternal devotion resulting from the complete or partial administration of anaesthetics in childbirth."

Animal experiments are notoriously misleading when their results are applied to human activities without previous clinical trial. Dr. Hadfield's quotation of the experiment upon Kaffir buck proving no exception. I can give two experiences with other species which counter the conclusions to be drawn from anaesthetizing Kaffir buck during parturition. One was that of a broody hen who, like countless of her sisters, successfully hatched a clutch of eggs not her own. It was so long since she had laid an egg that she must have completely forgotten the feelings associated with the "pains of labour" (if indeed an egg is painful to lay), yet her maternal devotion was so fierce that she flew at all and sundry who approached her foster chicks except the writer, who had administered to her each day while she was "sitting." Another example is that of tigresses, who appear to lose all maternal instinct during captivity. At Whipsnade before the recent war tiger cubs were continually being deserted and had to be taken to Regent's Park, where they were reared by a collie bitch who growled fiercely if anyone approached the cage behind the scenes where they were kept. These two examples show how little the pain of childbirth has to do with maternal devotion in species other than that of the Kaffir buck, which latter probably refused their offspring because they did not see them born (during the anaesthetic) and failed to recognize them subsequently.

As an anaesthetist I have during the past sixteen years given scores of anaesthetics during childbirth to wives of personal friends and colleagues. Most of these mothers I meet fairly frequently and can assure Dr. Hadfield that their mother love is in no way diminished. In addition, I have yet to meet the father whose paternal affection is in any way affected by being denied a participation in the pain of parturition.—I am, etc.,

King's College Hospital.

A. H. GALLEY.

National Hearing-aid

SIR.—In a letter (June 12, p. 1154) "Hearing-aid Wearer" gives examples supporting her claim "that very great changes are required in the training of those who fit hearing-aids to new wearers and of those responsible for their maintenance." She cites several preventable difficulties leading to acute distress which she and others have met with in their endeavour to mitigate their great handicap.

It is because I sympathize with her so sincerely that I call her attention to an article by Mr. R. Scott Stevenson (May 22, p. 990) on the "Working of a Hearing-aid Clinic." She will there learn that a hearing-aid clinic such as she demands is actually in existence. To quote the article in question, "The Metropolitan Ear, Nose and Throat Hospital started its Hearing-aid Clinic in the spring of 1937 in conjunction with one of the afternoon out-patient clinics." In spite of the setback occasioned by the outbreak of war it has met with such success that, the article continues, it "at present occupies four rooms, works to an appointment system, and is open every day from 9.30 a.m. to 5 p.m. (often later), except on Saturdays, when its hours are 9.30 a.m. to noon." Since no one can do good audiometry "without knowledge of the methods available and the problems to be met" (ibid.) the hospital has not only its own trained audiometrists, it also trains others. This instruction entails in addition to a sound technique a real understanding of the special problems of the deaf and wisdom in their handling. It follows that the audiometrists trained in this way have a practical grasp of the best method of helping the patient to choose the best hearing-aid. As Mr. Scott Stevenson pertinently remarks in the same article, "Comfort in hearing is as important in making a choice as is clearness."—I am, etc.,

London, W.1.

HILDA WEBER.

Biography of Banting

SIR.—The review of the biography of Sir Frederick Banting (June 5, p. 1084) I read with considerable distaste. In the first place as a review and criticism it is of no literary merit whatsoever, and secondly it gives the intending reader no idea of the real substance of Lord Stevenson's book. I have recently read this book and found in it all that I could possibly want to know of Banting and his achievements. In particular I feel that Dr. Stevenson has given us a very clear picture of the basic character of Banting, and has revealed how a simple farmer, being with many of the faults and a few of the virtues, goes to make up the average type of individual. Dr. Stevenson, I feel, has stressed the particularly obscure and must be remembered that at the time of and for a while after the discovery of insulin Banting was a common little fellow, a poor man, a saviour of mankind, rather than by the way a rich and he describes so well the nature of Dr. Banting in the exalted position in which he was placed. He also gives us a clear insight into the nature of Dr. Banting's mind, and the descriptions of the part in his life and the end of Dr. Banting's travel do not add a doubt.

None of this has been mentioned by your reviewer, and in my opinion, a serious omission for apart from the discovery of insulin Banting was a most interesting and a most human character.—I am, etc.

London, S.W.19.

GEORGE F. B. H.

Viennese Twilight

SIR.—May I say a few words in support of Dr. B. Aschner's constitutional theory which he defends in a letter in the *Journal* of May 12, p. 1002? Approximately 15 years ago, after his *Technik der Konstitutionsdiagnostik* appeared he was invited by the Medical Society in Bratislava (Czechoslovakia) to give a lecture, and there he was strongly attacked by two leading physicians for his "scientific" views. Then I rose to speak, reporting on some successes which I attained by Aschner's methods in a few cases of psychosis and nervous organ complaints. Official psychiatry in Vienna deemed it a scientific duty to reject Aschner's suggestions, as well as to deny his right to discuss the treatment of mental disorders, since he was lecturer in gynaecology. Nevertheless, not a few neuro-psychiatrists and physicians employed some of his methods.

However small the number of cures achieved by Aschner might have been, they concerned patients of a large variety in whom customary clinical treatment had utterly failed. We may or may not accept the view that emetics, drastic laxatives, hydrotherapy, and bleeding rid the organism of toxic substances; undeniably, for the unbiased observer, these measures do seem to work in some cases.

For the psycho-analytically minded physician an alternative or additional explanation offers itself. All the procedures mentioned stimulate organs and functions which we must regard as the somatic contributories to emotionality. The significance of affective cathexis of organs need not be particularly stressed in this era of psychosomatic medicine. Likewise, the fundamental role of the affect-ego (the perception of the self by feelings) in mental health will be before long generally acknowledged. So it is possible to approach Aschner's suggestion from an angle that strikes one as more modern than the idea of crude detoxication.

No doubt the impression made by Aschner's publications on the mind of a modern physician might create confusion; one can hardly rid oneself of the feeling that what he advocates is a return to primitiveness. This, however, is perhaps an emotional reaction rather than an intellectual; and the psycho-analyst is suspicious of such responses, even if they come from excellent physicians.—I am, etc.,

Londor W.1

S. LOUW.

Test of Death

SIR.—In Dr. A. P. Luff's *Textbook of Forensic Medicine and Toxicology*, London: Longmans, 1895 (vol. 1, p. 40), what I have found a very useful test is described—that it is impossible to press the pupil out of its circular shape during life. A medical man is not often present at the actual time of the death of a patient, but I have found this test very useful when I have been there. On one occasion a nurse said to me, "He has gone," but as I could not press the pupil out of its circular shape I said "No." The patient breathed again once and then I could press the pupil out of its circular shape. There was no further respiration.—I am, etc.,

NA SMITH GIM

G. P. BLECHLEY.

Chicken-pox with Paralysis of Leg

SIR.—I think that this unusual combination is worthy of record. A male child, aged 4, started with a mild attack of chicken-pox, which is epidemic in this area at present. There were apparently no constitutional symptoms. Six days after the onset of the rash he complained of inability to stand up, and examination revealed an almost complete paralysis of the left quadriceps group of muscles. The knee jerk was normal throughout. There was no rash to suggest an associated herpes zoster with motor paralysis. Pain was not complained of and there were no constitutional symptoms. The following day there was considerable improvement, and on the next day motor power was apparently normal. A lumbar puncture was not done. Three weeks later there was no evidence of motor weakness.—I am, etc.,

St Helen's Lane

JAMES KAY.

Doctors and Clergy

SIR.—The subject of co-operation between doctors and clergy was discussed at the Annual Conference of the Church of England Hospital Chaplains Fellowship which was held recently at St. Leonard's L.C.C. Hospital, Shoreditch. The Rev. F. S. Sinker, himself a doctor, pressed for a closer understanding among the rank and file of the two professions. While he admitted faults on the part of the Church, notably in giving insufficient training for hospital chaplains, he claimed that the priest's ministry is concerned not only with giving consolation but also with the actual conquest of disease. Doctors could help the work of chaplains by discussing cases with them, giving them the prognosis, indicating anything that might retard recovery, and agreeing on the chaplain's lines of treatment. The chaplain might come across facts concerning a patient's social background or moral condition which might have considerable influence on the course of treatment prescribed. By conversation and by the use of the Sacraments in

suitable cases he could help to instil the will to recovery, to give insight, and set the mind at rest over social problems.

The conference was also addressed by the superintendent physician of Horton Hospital, Dr. W. D. Nicol, who outlined the psychological background of disease and indicated how chaplains could assist the cure of functional disorders; and also by Canon Lindsay Dewar, who claimed that the existence of the soul must be regarded as a fact and a fact that must be reckoned with in considering the integration of the whole human personality. A belief in divine forgiveness was, he asserted, in some cases a prerequisite of physical healing.—I am, etc.,

BERNARD A. WALL.
Hon. Sec., Church of England
Hospital Chaplains Fellowship.

London, E.8.

"Young" Doctors

SIR,—Is it not time that the B.M.A. should shed some light on the possible future of the ever-increasing number of "young" ex-Service doctors? What nonsense is written and spoken of the "shortage" of doctors—general practitioners and specialists. Flight Lieutenant G. J. E. Ansell expressed the state of affairs for those wishing to enter general practice (May 22, p. 1004), and one has but to apply for a senior hospital appointment to see the "shortage" of specialists—would-be or established. Indeed, one needs only to glance through the columns of advertised posts for medical and surgical registrars to see that there is no shortage of men who are preparing to be the specialists of to-morrow, for what hospital committee would dream of offering such scandalously low salaries to men who "must hold diploma of F.R.C.S. of Eng. or Ed." or "must hold diploma of M.R.C.P." if there were any shortage?

At present my family's income would be higher if my wife went out to work and I stayed at home to look after the baby. My wife is a member of the Society of Radiographers, and in return for 18 months' study she is able to command a higher income for 35 hours' work per week than most hospital residents receive after six years' studying to qualify, plus a variable number of years' postgraduate study for higher qualifications. It is surely time that more concern should be shown for the so-called "young" doctors—young in the profession, perhaps, but old enough to have served their country, and old enough to be husbands and fathers.

No longer can it be said that it is an honour and a privilege to work in a hospital for a low salary, and that the future will reward us well; no longer will we be able to earn large incomes in private practice after a period of poorly paid hospital appointments, and so "make up for it," as one of my ex-chiefs used to put it. Without capital the ex-Serviceman can neither settle down in general practice nor work for years in hospital for a mere pittance while becoming a mature specialist.

At present many of us are "unemployed" and, in fact, on a glorified dole, being supported by Ministry of Education grants (for which we are grateful) while we continue preparing for higher qualifications; but this cannot go on for ever, and when these postgraduate qualifications are won and the grants stop where are we to find the necessary jobs to bring in an adequate income? It is all very well loving one's work, and enjoying the privilege of serving the sick, but this does not support a family or pay for the upkeep and education of the next generation.—I am, etc.,

London N.W.6

P. HOPKINS.

Medical Photography

SIR,—What exactly would be the position in a hospital if every clinician was indeed to take his own medical photographs—as envisaged by Dr. J. H. Twiston Davies (May 22, p. 1001)? Surely chaos worse confounded. Dr. Twiston Davies airily says "the hospital need only provide a studio, some non-mobile equipment, and the part-time services of a technician for professional work." Leaving on one side the argument that the task of a clinician is to tend patients and not to take medical photographs, let us consider what fun there would be in the studio with its non-mobile equipment when several clinicians, each with different types of patients, were competing for the use of the apparatus and later for the services of the part-time technician. On a practical incidentally, what the technician would do with

the other part of his time after he had processed and print the efforts of the clinicians and done the necessary filing a record work—if Dr. Twiston Davies regards this as necessary.

Are the clinicians to give proof of any photographic ability before they are let loose with the non-mobile equipment, and the hospital to pay for the cost of the photographic material these clinician-medical-photographers use in their efforts? Dr. Twiston Davies says, "The hospital photographic department is an absurdity based on a misunderstanding of the function of art in medicine." Would he also say that "the hospital physiotherapy department and the hospital x-ray department are absurdities based on a misunderstanding of the function of electricity in medicine"? Of course not, so why should he condemn the medical photographer whose work aids in teaching the medical student, records the progress of the patient while the clinician is treating him, and assists the clinician in arriving at his diagnosis?

Every teaching hospital should have its own department of medical photography—not only to serve the needs of teacher-clinicians who are too busy doing their proper work to take medical photographs, but also to supply the ever-increasing demand for the many forms of visual teaching aids now in request by medical teachers.—I am, etc.,

Department of Medical Photography,
St. Bartholomew's Hospital, London, E.C.1. NORMAN K. HARRISON.

R.C.S. Suppression of Opinion

SIR,—In the annotation headed "Surgeons in Camera" (May 8, p. 888) you referred to the meeting of Fellows of the Royal College of Surgeons of England held on Wednesday, April 28. That meeting was summoned by a requisition of March 11, signed by 33 Fellows in order to discuss the position of the National Health Service Act in relation to the British Medical Association plebiscite held early this year. The importance of that meeting lay in the fact that it was the first meeting of Fellows (who are the electors of the Council) held since the Act became law at which resolutions dealing with the Act had been permitted. It is regrettable that the three resolutions which were passed at the recent meeting criticizing the Act should have been withheld from the profession and from the public.

A meeting of Fellows on Nov. 29, 1946, was held without the three weeks' notice required by the regulations, and this prevented resolutions from being put forward. Subsequently, when resolutions were put forward at the meeting, they were ruled out of order because notice had not been given, but the medical press were present and the meeting was reported in your columns (Dec. 7, 1946, p. 869). The recent meeting was advertised in the medical journals and attended by Fellows from all over the country. On arrival the Fellows found the agenda paper had been marked "confidential." No preparation had been made for scrutiny of voting, and no preparations had been made for a ballot. After some two hours, when a ballot was called for on the second motion, the meeting was declared secret. It subsequently appeared that the medical press had been excluded from the meeting, and no report of the meeting and the resolutions has as yet appeared in the medical or lay press.

During the past few years the President of the Royal College of Surgeons has used his position and prestige to make pronouncements about the policy of the College as a corporate body—pronouncements that have profoundly influenced both public opinion and the course of events. Those pronouncements would have been more acceptable to the medical profession had there been any evidence that they also represented the views of the Fellows. The recent resolutions were the considered views of the Fellows, and as such should have been accorded the publicity which presidential announcements have received in the past.

The ancient structure of the Royal College of Surgeons may be adequate for dealing with routine College business, but it is not adequate for politics. If the College is to take part in medical politics it is essential that in the future the Fellows should have a ready and speedy method of making their views known. The Fellows of the largest medical college in the country are a responsible body of men, and their views should be of value both to the medical community and to the

community at large. The recent resolutions at the Comitia of the Royal College of Physicians were published in both the medical and other journals, whereas the resolutions passed at the recent meeting of Fellows of the Royal College of Surgeons have not been made known either to the medical profession or to the public. The fact that such a suppression of opinion can occur is a serious criticism of the constitution of the College of Surgeons.—We are, etc.,

Professional Confidence

SIR.—The Lord Chancellor, in his speech in the Lords on the Second Reading of the N.H.S. Bill, which became the Act of 1946, declared that the "very great powers" entrusted by its provisions to the Minister of Health gave him the position of commander-in-chief of an army in the field (Lords Hansard, Oct. 8, 1946). This analogy prompts consideration of the position of medical officers in the fighting Services and lends point to a subject which has been brought to my notice by a medical constituent serving as M.O. to an R.A.F. unit in Germany. He writes that, at a conference of A.O.C.s held in November, 1947, at an R.A.F. unit in Germany attended by all doctors, padres, and commanding officers of the wing, M.O.s were reminded that a long-standing regulation required them to divulge to the commanding officer the names and full medical details of patients under their professional care suffering from venereal disease. It further appeared that these records thus obtained could be passed on to others than the C.O. and could furnish data which could influence the subsequent career of the individual concerned. In this connexion an *inter alia* clause to M.O.s is quoted: "where personnel, civilian or military, is considered *ipso facto* that they are lacking in qualities required of service personnel and that promotion or the grant of short-service or permanent commissions or re-engagement is likely to be jeopardized thereby." The question of the retention in the Service of per cent offenders should be carefully considered.

I approached the Minister for Air with a view to having these facts were correctly stated and received his confirmation that such a conference was held at which the regulation as described was brought to the notice of the participants. It is pleasant to record that some A.O.C.s have agreed to comply. The Minister, however, has referred the service authorities are "informed" that their rule and that the regulation is necessary to preserve the discipline of the troops and has been in force for a long time in all the Services.

Under the new Health Act the well as doctors will come under similar discipline. This will be required to compile far fuller records of patients than at any time previously, and is consequently to be given due consideration in doing so. The records are to be kept in the hands of the authority, and will thus be accessible to the eyes of many lay persons. I submit, therefore, that the regulation constitutes a practically complete destruction of the rule of the professional secret which has been the basis of the rule of the profession for the time being. It is a blow to my medical colleagues. To your Terms of Service, etc.

House of Commons.

Terms of Service for Specialists

SIR.—Now that major differences between the profession and the Minister are being settled, it is pertinent to call attention to certain lesser matters which would therefore mention four points relevant to the terms of service for whole-time specialists.

(1) *Superannuation*.—M.O.s will have to make a choice between alternative scales. The differences between these are in

many cases rather subtle, and there would seem to be a definite opportunity for actuarial advice from the B.M.A. as to the most advantageous choice in different types of work. If this is not practicable, then many of us will have to employ an actuary to guide us as to the best choice.

(2) *Travelling Allowances*.—Previously there have been wide variations in the scales paid by different authorities. It should be agreed that in the new Service nobody shall be the worse off in this respect, and especially should agreement be reached as to the allowance in respect of replacement of a car nowadays, an item which has often been conveniently ignored in recent years.

(3) *Lecture Fees*.—Presumably the remuneration of specialists will be for services rendered in regard to the diagnosis and treatment of patients. However, most specialists do a certain amount of incidental lecturing on their specialty, especially to the nursing profession, and much of this has hitherto been given without remuneration. Is the State expecting that in future its nursing employees will continue to receive a substantial part of their general and special training by free lectures from its medical employees? Should a scale of lecture fees be recommended by the Association?

(4) *Clinical Society Meetings*.—Of recent years the more progressive local authorities have increasingly appreciated the value of merely permitting but encouraging their medical officers to attend the various meetings of important clinical societies in their specialties, and paying their expenses to go to such meetings. It is unnecessary to stress the importance of this or to call attention to the fear-reminiscent backward authorities which still obstruct the efforts of their medical officers to attend such very useful meetings. A clear understanding ought to be reached in the new Service that a specialist will be expected to attend the meetings of important clinical societies, and a definite agreement should be reached regarding expenses and leave of absence to go to such meetings at a certain annual provincial meetings at which medical officers from all over the country—and often from abroad—attend. It is a very stimulating and refreshing.

—I am, etc.

ROBERT JACK.

15, 11, 10, 10, 10, 10.

The S.R.M.

SIR.—I have many others with whom I spoke after the S.R.M. I can only find a few to disgust, first, the split in the profession for which I hold the Council and in particular the Presidents of the Royal Colleges responsible and secondly at the arranging of free speech in what I have always hitherto thought to be a democratic body. I was glad to read Mr. C. E. EVANS' letter (June 12, p. 1155). My own case was similar, but if anything a more flagrant straggling.

Following Dr. Cove-Smith's request for an alteration in the order of the agenda I put the following question to the chairman: "Is not Recommendation A nothing but a thinly veiled vote of confidence in the action of the Council, and, if it is passed, will it not be your duty to rule as 'out of order' motions 56 to 70?" (the motions criticizing the action of the Council and the *Journal*). In reply the chairman definitely stated that he would not rule them out of order and we should have plenty of time to discuss them in the afternoon. My Division had sent me up with a motion, tabled 57 on the agenda, and I was on the rostrum ready to speak while No. 56 was being debated. Representatives will remember that during this debate a point of order was raised from the Hall: "As we have agreed to Recommendation A, are not this and succeeding motions dealing with the action of the Council out of order?" The chairman thereupon (I thought with almost indecent haste) replied, "I rule them out of order." I went across the rostrum to him and reminded him of his assurance to me of the morning, only to receive the reply, "I have ruled them out of order." I am convinced that the motion to change the order of the agenda was lost because of the promise by the chairman to allow the motions of censure to be discussed in the afternoon, but it would appear that it had been the intention of those in high quarters that these motions should be suppressed.

The meeting appeared to start as though charged with high-tension electricity, with all exits heavily mined with high-explosive and with machine-gun nests in all strategic positions, but before long it became apparent that the wires had been short-circuited, the fuses of the mines drawn, and the machine-guns loaded with blank ammunition. I write this letter at the request of and with the full approval of my Division.—I am, etc.,

A. G. HOLMAN.

East Norfolk Division.

Remuneration of Specialists

SIR.—The Spens Report at last gives hope to the whole-time specialist that his services will be adequately rewarded. The recommendations still have to be interpreted by bodies yet to be formed, and here there are endless possibilities for injustices. It would of course be impossible to cover every individual case by general regulations, but the problem of the ex-Service specialist is one where great difficulty may be encountered in assessing the salary of individual persons.

Let us have it clearly understood that those who during the war joined the Armed Forces before being appointed to the staff of a civil hospital have, since demobilization, been at a disadvantage in obtaining suitable employment compared with those who remained civilians; also that Service specialists on the staffs of Service hospitals were the equals of their civilian colleagues who enjoyed similar responsibilities in different circumstances; and that therefore military service as a specialist in charge of hospital beds should count in the same way as civilian experience when the number of increments to which one is entitled is being considered, regardless of the status of the appointment at present being held.—I am, etc.,

Birmingham.

W. M. PHILIP.

Working in the N.H.S.

SIR.—The National Health Service Act comes into operation on July 5, 1948. Following the Representative Meeting of the British Medical Association on May 28, 1948, it is incumbent upon every practitioner participating in the scheme to co-operate whole-heartedly and to make every endeavour within his limited scope to ensure the success of the Health Service in the national interest. The Minister of Health, Mr. Aneurin Bevan, in formulating and drafting all the necessary steps in this great national movement, expressed deep concern for the past hardships in life which had inevitably to be faced up to by the doctors. The hardships to which the Minister referred were particularly stressed as being: (a) The purchase of a practice by the young doctor, thus giving him a millstone for probably ten years; (b) the health of the doctor suffering through long arduous hours of work and being on duty 24 hours out of 24. The Minister considered that no doctor could give of his best living in such an overworked and harassed state.

The Minister in giving the nation the National Health Service has effectively eliminated the first of these factors (the doctor's millstone). The question of the doctor's working hours and hours of duty cannot at the moment be dealt with by the Ministry owing to the facts that: (a) No health centres are built; (b) not sufficient doctors to maintain a normal working week (as is obtained in other spheres of life); (c) not enough specialized equipment for the hospitals and clinics; (d) not a sufficient number of nurses to aid any clinics or even to maintain the present hospital beds at full strength. Bearing all these facts in mind the Minister has stated that he would like the doctors to encourage partnerships and group practice so that adequate self-organization can be put into operation in order to facilitate the working of the Act and in order to work in close co-operation, thus enabling each man to have adequate leisure and periods of rest.

SUGGESTED SCHEME FOR DISCUSSION

All the hospital out-patients and clinics (which are equivalent to the doctor's surgeries) are as far as possible always held in the mornings.

All the new health centres (when built, equipped, and staffed) will hold their clinics in the mornings. In all instances only a skeleton staff of doctors are left on duty each evening to cope with emergency medical cases and accidents.

This scheme above as at present obtains in our hospitals and out-patients should be applicable to the general practitioners' surgeries or clinics, thus enabling the doctors to give the Minister the full co-operation he desires in order to make the Act a success and relieve the doctor to a certain extent of the strain of overwork.

The plan is therefore open to discussion: That general practitioners' evening surgery completely and thus fall into line with the hospitals and health centres (future). (a) It is suggested that the present morning surgery, usually one hour—i.e., 9 a.m. to 10 a.m.—be extended into a morning clinic lasting from, say, 8.30 a.m. to 11 a.m., or alternatively 8.30 a.m. to 10.30 a.m. as desired. (b) That a portion of early evening should be devoted to an out-patient and general clinic, and at this time diphtheria immuniza-

tion could be undertaken. (c) Following the morning clinic the routine visits can be completed. (d) On an average day (epidemic excepted) the doctor's work should be finished by, say, 6 p.m. (e) In partnership practices organization and mutual help could produce a rota system whereby after a given time, say 6 p.m., or two doctors according to the size of the firm could remain on duty for emergencies and night calls. (f) In the case of the single-handed doctor a mutual working arrangement can be made either with another single practitioner or he could take his turn in the system of the firm for night duty.

It should not be overlooked that under the new system at least estimated 80% of all private patients have gone who under the old system were panel dependants.

What would be the advantages under such working arrangements?

(1) The patients would have added facilities in the extended morning time; this particularly refers to the women who often found the evening surgery inconvenient owing to the fact that men returning from work have to have their meals cooked.

(2) The fact that some people would miss their morning work would to a large extent deter the "lead-swingers" or people coming for trivial and idiotic things; thus the patient attending the morning clinic would for the most part really need medical attention.

(3) The expectant mothers could have a clinic of their own which so many women prefer.

(4) The doctors, if they co-operate, will know when the day's work ends and will not have to face a gruelling evening surgery.

(5) The doctors' wives would know in future what time the evening meal would be and not be forced to wait until surgery finished. In these days of little or no domestic help the doctor's wife is not only harassed by 'phone and door but frequently has to face the washing-up at 9 p.m. and 10 p.m.

(6) All that such a scheme as suggested calls for is co-operation by small groups of friends, and it would not only make for a happier and steadier life for the practitioner and his family but would also meet all the needs of the National Health Service in giving a better and fuller service to the public.—I am, etc.,

Soham, Cambs.

N. GRAHAM.

Dispensing in N.H.S.

SIR.—There is one aspect of the new Health Service to which singularly little attention has been paid—the dispensing of patients' prescriptions. All doctors practising in industrial or urban areas will give their patients prescriptions, which they will take to their nearest chemist. There are in some areas ten doctors served by one chemist, and in the winter months it is likely that as many as 500 patients will go to the chemist following busy surgery hours and ask for their prescriptions to be made up.

Chemists have no waiting-rooms, their shops are usually small and often not open during the evening surgery hours, and the resulting chaos may well be a feature of the new Service. It is quite possible that doctors will be asked to take over dispensing again, or else they will be partly blamed for yet another ill-prepared feature of the new Act. Is this problem being considered?—I am, etc.,

Doncaster.

R. W. L. WARD.

Post Office Medical Officers and N.H.S.

SIR.—Among the many anomalies and injustices of the so-called comprehensive National Health Service is that which affects part-time post office medical officers. These medical officers will in many cases lose the medical care of post office personnel which they have had for a number of years.

In the case of cities and large towns most of the P.O. employees on the medical officer's capitation list live outside in the suburbs. They will naturally select a doctor in their home area and thus the P.O.M.O. will lose them as patients. Not only will a happy relationship between the P.O.M.O. and patient be lost, but the P.O.M.O. will be heavily hit financially in the case where he has had medical care of a staff of 600 or so post office employees. The new Treasury medical service will no doubt afford him some form of remuneration in the matter of special reports, etc., but this will not nearly make up the monetary loss. In fact, in cities

ROBERT POOTS.

Obituary

BRITISH
MEDICAL

A. M. GOSSAGE, C.B.E., D.M., F.R.C.P.

Dr. A. M. Gossage died on June 8 at the Westminster Hospital, where for many years he had been consulting physician. Alfred Milne Gossage, the second son of William Herbert Gossage, was born in Lancashire in 1864. He was educated at Clifton and Magdalen College, Oxford, where he took a first-class in natural science in 1886 before going on to the Westminster Hospital. He qualified in 1890, and graduated B.M., B.Ch. in 1891. He was house-physician at the Brompton Hospital and medical registrar at the Westminster Hospital before going on to the honorary staff. Dr. Gossage was elected F.R.C.P. in 1903, and proceeded D.M. in 1907. Apart from his long association with the Westminster Hospital he was also physician to the East London Hospital for Children, which later became the Princess Elizabeth of York Hospital for Children and in 1942 was united with the Queen's Hospital for Children to form the Queen Elizabeth Hospital for Children. Dr. Gossage contributed a number of articles to the medical press and was also responsible for the sections on heredity and syphilis in Garrod and Batten's *Diseases of Children* and for the accounts of Raynaud's disease and infantile convulsions in *System of Treatment* edited by Latham and English. He was a member of the British Medical Association for many years and was secretary of the section of Diseases of Children at the annual meeting in 1900.

Dr. Gossage will be remembered as a good physician and an earnest teacher. He was also a charming person and a trustworthy friend. During the first world war he served in the R.A.M.C. with the rank of major, and in 1920 he was awarded the C.B.E. He married Bertha Pillans, third daughter of Pillans Scarth Stevenson, of Montreal, and they had a son and a daughter. He had been living for some years past in retirement at Chalfont St. Giles.

C. J. PATTEN, M.D., Sc.D.

Charles Joseph Patten was born at Ballybrack, Co. Dublin, in 1870. He died, after a very brief illness, at his home in Farnham, Surrey, at the age of 78. He had been living in Farnham for only about a year.

Patten was educated at the High School, Dublin, and proceeded to Trinity College. Here he took up the study of biology and of medicine. From the first he showed that aptitude for natural history which was so apparent to all who knew him in later years, and took a triple first in the senior moderatorship with a gold medal in natural science. After graduating in 1896 he joined Cunningham's staff as demonstrator of anatomy and was comparatively new, and the clear picture of topographical relations which it gave appealed with special force to the Irish school of anatomists. Working under Cunningham's direction, Patten shaped those descriptions until quite lately. It was natural, therefore, that in 1901 he should be called to fill the chair at the Sheffield Medical School left vacant by the resignation of Christopher (now Lord) Addison, shortly before he planned the new department of anatomy then set up, with an eye upon that of his beloved T.C.D., down to the detail of the parquet floor. He held his chair at Sheffield for thirty-four years, retiring in 1935 with the dignity of professor emeritus, of his many friends he continued to live in Sheffield, leaving it only after the second world war.

Prof. Patten was one of the last of the "classical" school of topographical anatomists. Many whose names are in the forefront of clinical medicine and surgery to-day received their introduction to anatomy at his hands; and he saw to it that the material they studied was both sufficient and well cared for. There are among the primary duties of the head of an anatomical school; he took them seriously. This may seem a small matter in these days of tissue culture and electron microscopy, but as Prof. Cave has said, the first business of

a professor of anatomy is to provide for the needs of the of medicine. There would have been no Harvey had been a Vesalius before him.

One of the earliest members of the Anatomical Society Patten served on its council and contributed many papers to its meetings. He was external examiner to several in England and Ireland, and was unusually popular with candidates. To the general public, however, he was best known as an ornithologist. He had an extraordinary both popular and scientific papers on their ways. He put of their calls and song. He was a good mimic and interested in choral music, human as well as avian. He special interest, too, in the problem of bird migration, in many weeks a year in off-shore lighthouses around the coast that he might gather data for its solution. Two and informative books sum up his observations on this subject. As a man he was a most kindly chief, and a assured of a delightful evening. Those who came to his house and State often differed profoundly from those of his but that made no difference to the welcome they received. later years were clouded by a severe affection of his eyes, this did not seem to dim his essential good humour. He a widow, a son, and a daughter, to whom we extend our sympathy.—M. A. MacC.

Prof. Francis Davies writes: Patten's anatomical were in the field of physical anthropology, particularly variations in skull osteology in primates and anomalies in human myology. But his great interest over many years was the study of bird life, and it is in this sphere that he became known. He studied birds as a naturalist rather than as an ornithologist; it was their ways and habits, their nesting, and particularly their migration that appealed most to him. He was numerous papers and several delightful books on bird life, and was an excellent photographer. His book *The Aquatic Birds of Great Britain*, which was published in 1912, is a standard work of cheerfulness, his generosity, tolerance, ready help, and pronounced sense of humour. He had the gift of excellent and could imitate the sound and song of numerous birds. Australia he added several bird songs to his repertoire used to delight and startle his colleagues with the cry of a laughing jackass. He prepared a fine collection of bird skins many of which he presented to the Weston Park Museum, Sheffield. Patten was a devoted disciple of Charles Darwin, whom he literally worshipped. He will be missed by a wide circle of friends.

HENRY JELLETT, M.D., F.R.C.P.I.

Dr. Henry Jellett, who has just died in New Zealand, was a distinguished graduate of Dublin University. He was the son of the Very Rev. Henry Jellett, D.D., Dean of St. Patrick's Cathedral, Dublin, and was born in Killinardish, Co. Cork on May 29, 1872. After a successful undergraduate career he decided to specialize in midwifery and gynaecology. He graduated in 1894, proceeding M.D. two years later, and was elected F.R.C.P.I. in 1898. Having served his time as assistant master to the late Sir William Smyth at the Rotunda Hospital, Jellett became gynaecologist to Dr. Steevens' Hospital. Later he was appointed King's Professor of Midwifery in Dublin University and gynaecologist to Sir Patrick Dun's Hospital. He had only acted as professor for one year when, in 1910, he was elected Master of the Rotunda Hospital. He resigned his mastership in order to serve as commandant of the Munro Ambulance Corps in 1914, but when he returned from France in 1917 he was re-elected Master and completed the usual period of seven years. Towards the end of the war he was awarded the Croix de Guerre and was made Chevalier de l'Ordre de la Couronne de Belgique.

Jellett is chiefly known for his textbooks on midwifery and gynaecology, which had a world-wide circulation and went into many editions. During his mastership of the Rotunda he made many improvements, the most noteworthy being a new labour ward. He was a very skilled operator and was the originator of a useful addition to the prolapse operation—a shortening of the utero-sacral ligaments which are cut away from the

OBITUARY

posterior surface of the cervix and sewn in front. At one time he advocated prophylactic pubiotomy, suggesting that the pelvis could be measured and pubiotomy done at about the sixth or seventh month, but this idea never became popular. When he finished his term as Master at the Rotunda he emigrated to New Zealand, where he was appointed consulting obstetrician to the Health Department. He told the writer that the climate of Ireland was giving him rheumatism. His very dominant character did not appear to suit the New Zealanders, and during his last years he devoted himself to growing apples and to his favourite sport of fishing. Jellett could not be called a popular man, but he was a very sincere worker in the fields of gynaecology and obstetrics and his work will be remembered for a long time.—B. S.

MAX HIRSCH, M.D.

Dr. Max Hirsch, who was one of the best-known gynaecologists in Germany before the war, died on May 20 in Birmingham at the age of 71. He qualified at Berlin University in 1901, and from the start of his career he applied his knowledge of gynaecology and obstetrics to the problems of social medicine, eugenics, anthropology, biology, and psychology. He founded in 1912 the *Archiv für Frauenkunde und Konstitutionsforschung*, and two years later published the results of an inquiry into the causes of the decrease in the birth rate, with particular reference to abortion and birth control. Other monographs he wrote were on gynaecological diseases in certain industries and on the effects of occupation upon pregnancy and childbirth in Saxony's main textile district. Some of his notably those on medical marriage certificates, marriage counsels, and maternity allowances, helped to bring about legislative changes. In Halban and Seitz's *Biology and Pathology of Women*, Hirsch wrote the chapter about the relation between occupation and the diseases of women.

Hirsch initiated in 1927 a statistical and clinical inquiry into the results of obstetric practice over the preceding fifty years. His conclusion that the achievements of obstetrics in Germany had not kept pace with the progress of medicine provoked much discussion. Finally a special committee was set up by the Leipzig Society for Gynaecology and Obstetrics. Hirsch was a member of this committee, and his *Reichs-Birthstatistik* was accepted as a basis for further inquiries.

Hirsch was made a member of the Health Council of the Ministry of Public Welfare in 1919, of the German Committee on Population Policy in 1928, and he had been president of the Association of Medical Sexologists since 1922. He edited the *Handbuch der Inneren Sekretion*, published in 1932, conducted a large consulting practice, and gave many lectures to postgraduate students.

All these activities came to an abrupt end in 1933, when, in line with the anti-Jewish policy of the Nazis, he was removed from scientific life and public positions, forbidden to practise, and finally imprisoned by the Gestapo. He found refuge in this country with the help of the Society for the Protection of Science and Learning, and after temporary registration had been in charge of maternity units until the beginning of his fatal disease in October, 1947. Hirsch was a man of outstanding personality and profound culture. He was especially interested in classics and in the literature of many periods. His friends from various walks of life saw how he bore his illness with admirable patience, fortitude, and dignity, knowing that the end was inevitable.—E. S.

WILLIAM LLOYD, F.R.C.S.

Mr. William Lloyd, who was honorary aurist and laryngologist to the Music Hall Benevolent Home, died at his home in Harrow-on-the-Hill on June 11 at the age of 73. William Lloyd was born in South Wales in 1874 and educated at the University College of Wales and the London Hospital, qualified L.S.A. in 1898 and took the Scottish triple qualification a year later. He was a house-surgeon at the London Throat Hospital and senior clinical assistant in the Nose, Throat, and Ear Department of the London Hospital. Later he was on the staff of the Kensington and Fulham General Hospital and built up a large practice among operatic, stage, and music-hall artists. He attended Signor Caruso on a charge of indirect advertisement which followed the appearance in a London newspaper of an article by a patient of his who was also a journalist. William Lloyd was not mentioned by name in the article and the action of the General Medical Council in this case was the subject of a question in the House of Commons a few days later. His name was restored to the *Register* in 1927. William Lloyd published a number of articles in this and other journals, and his best-known work was a book on hay-fever and hay-asthma, which went into a third edition in 1931.

Dr. R. Tudor Edwards writes:

The passing of Mr. William Lloyd last week at the age of 73, at Harrow-on-the-Hill, brought to its close a most interesting and dynamic life. His parents were farmers in Carmarthenshire. He was an enthusiastic Welshman, and recently remembered his old school at Carmarthen by endowing it with two annual scholarships of £50 each to be competed for by Welsh-speaking boys. In granting these scholarships he also presented to the school a set of original photographs of Captain Scott's Antarctic expedition. These were by Mr. Herbert Ponting, official photographer to the expedition. Mr. Lloyd was kind by nature, an individualist, forceful, and a very hard worker. He led a tumultuous life and, like his old patient, David Lloyd George, brought all his troubles on his own head. An example of this may be seen in that while he took the F.R.C.S. he never registered it because he objected to paying the registration fee—on principle. He lived in Brook Street, Grosvenor Square, from 1906 until the house was blitzed in 1940. During those years he was consulted by most of the leading singers, politicians, and musical artists of bygone days. Their gratitude is demonstrated in hundreds of letters and tokens. A large photograph of Caruso, who was his patient on and off for fifteen years, bears the message, "To William Lloyd, with the most profound expression of sympathy and friendship—Enrico Caruso." He was a keen sportsman and played rugby for the London Sporting Club for forty years. During the 1914-18 war he organized a matinee at the Alhambra for London Welsh troops which raised £8,000. He travelled the world over and was a great lover of nature, but was never happier than when talking of his native Wales.

Dr. GERALD CHAMBERS, who died on May 19, graduated at Leeds in 1924, and at an early stage of his career decided to specialize in radiology. After a short time in London, when he was assistant radiologist to St. George's Hospital and clinical assistant in radiology at the London Hospital, he was appointed radiologist to the General Hospital, Shanghai. He remained there until shortly before the war, when he returned to this country. He settled in Plymouth and was appointed radiologist to the Prince of Wales Hospital. In 1941 Dr. Chambers joined the Royal Air Force and was in charge of the radiology department at a large general hospital until the end of the war. On first acquaintance "Tom" Chambers was rather shy, but when his natural reserve was penetrated he showed himself to be the kindest and quietest of friends. His sound common sense and endearing him to all who were fortunate enough to get to know him. He possessed a very equable temperament, but could not stand injustice, and this alone could rouse him to anger. He was a first-class diagnostician with a wide experience which made him a valued member of the hospital staff. Since his demobilization in 1945 he had suffered from constant and gradually increasing pain. This he bore with great fortitude, and his passing was to him a relief. He leaves a widow, two daughters, and a son, and to them our deepest sympathy is extended.—A. W. B.

Dr. FRANK GORDON MACNAIR died at Avondale on May 26 at the age of 46. He graduated M.B., Ch.B. at Edinburgh in 1925, and was in general practice in Dumfriesshire for a short time before becoming an assistant in the department of pharmacology at Edinburgh University. He proceeded M.D. in 1930, and moved to Marple, in Cheshire, where he again entered general practice and established a reputation as a wise and understanding physician. Dr. Macnair devoted much of his time to the Stockport Infirmary in the capacity of assistant medical officer only when he decided to concentrate on the study of psychiatry. He had already taken part of the D.P.M. when his final illness developed. He leaves a widow and two children, and will be widely missed not only by his former patients but by a large circle of friends.—D. R. A.

Medico-Legal

CONTRACEPTIVES AND NON-CONSUMMATION

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

The troublesome decision of the Court of Appeal in *Cowen v. Cowen*, which held that insistence on the use of a contraceptive could amount to wilful refusal to consummate a marriage, was declared invalid by the decision of the House of Lords in *Baxter v. Baxter*.¹ Consummation means in law what it means in ordinary speech, and intercourse even with the use of a contraceptive is consummation. In the case of *Horton v. Horton*,² decided about the same time, their Lordships' House declined to define the phrase "wilful refusal of consummation," but said that it connoted a settled and definite decision come to without just excuse. Similarly, the Attorney-General stated on Jan. 27, when asked by a member at Question Time, that the Government did not intend to introduce amending legislation to nullify the effect of *Baxter v. Baxter*. The member described the present definition of consummation as pernicious and contrary to public policy, but the Government held the view that this was one of the fields of human relationship—not now very numerous, some may think—which cannot properly be dealt with by legislation. The Attorney-General hinted that there was some misunderstanding of the effect of the decision. He pointed out that the case did not decide that one of the parties to the marriage was entitled to refuse marital relations unless contraceptives were used, nor that where they were so refused the other party had no remedy. The Lord Chancellor said in deciding the *Baxter* appeal that the proper occasion for considering the subjects raised by it was when the sexual life of the spouses and the responsibility of either or both for a childless home formed the background to some other claim for relief. Examples given recently by a learned writer³ were a divorce suit based on desertion or cruelty, or the defence of a suit brought on some other ground by a spouse guilty of such a refusal. This writer, however, did not see very much importance in such a "background," for desertion requires actual separation for three years, and desertion of the "constructive" kind envisaged here, in which the petitioner has left the home because the respondent has made life in it impossible, requires conduct amounting to expulsion. A suit based on cruelty requires proof of injury to health or a reasonable apprehension of it.

Two Relevant Cases

An actual case, however, was decided recently by the High Court⁴ in which (as the *Law Notes* writer points out) refusal of normal intercourse was held to provide reasonable ground for a husband to leave his wife. This husband had been very anxious to have a family, but the parties had decided not to have children during the war. After the war the wife refused to bear a child or to allow normal intercourse, and the justices believed the husband's evidence that she was always nagging and "bawling" at him. There was a final quarrel, the husband left the home, and both parties petitioned for nullity on the ground of non-consummation, but neither was able to prove the case. The wife then summoned the husband for maintenance, and the bench dismissed her summonses, holding that her conduct was such that normal married life was not possible, and that she was not genuinely prepared to cohabit with the husband again. The wife appealed to the Divisional Court, and Lord Merriman, the President, said that every word of the Lord Chancellor's remarks, in *Baxter v. Baxter*, about the responsibility of one or both spouses for a childless home forming the background to another claim for relief applied precisely to the present case, and the justices had been quite right in assessing the bearing of the parties' sexual life on the parting between them. But he emphasized that there was nothing irrevocable about any of these matters. Although the wife had been sterilized by an operation, she could mend her ways and resume cohabitation in the full sense of the

word; if she did so, the husband would not be entitled to take the view that it had been finally decided that because she had refused to bear children the marriage was at an end.

On the other hand, the "background" did not help another husband who asked the court to allow him to present a petition for divorce before three years had elapsed from the date of the marriage, a course only allowed if the court considers it justified by exceptional hardship.⁵ He maintained that his wife's refusal to allow intercourse without a contraceptive because she did not want children constituted the exceptional hardship required by Herbert's Act. Mr. Justice Pilcher refused, and the Court of Appeal supported him. Mr. Justice Bucknill said that married couples ought not to be encouraged to take such an ill-advised step as to sue for divorce merely because things had gone wrong. On the husband's other ground of exceptional hardship—namely, that he had not been able to get his petition for nullity heard and decided before the House of Lords' decision in *Baxter v. Baxter*, which laid down that a marriage can be consummated by intercourse with a contraceptive—the Lord Justice said that the contention had no merit and that those who got their decrees before *Baxter v. Baxter* were the lucky ones.

Coitus Interruptus

Another question that has given rise to a difference of judicial opinion is whether a marriage has been consummated when there has been no intercourse except coitus interruptus.⁶ This question was also left undecided in *Baxter v. Baxter* but has recently been considered in two other cases. On May 10 Mr. Justice Finnemore in the undefended case of *Grimes (otherwise Edwards) v. Grimes* held that the husband's insistence on the practice against the wishes of the wife amounted in law to wilful refusal to consummate the marriage. It was not natural or complete intercourse and it could be distinguished from the practice of using contraceptives.

On the following day Mr. Justice Willmer, in the defended suit of *White (otherwise Berry) v. White*, disagreed with this decision. He held that coitus interruptus was not wilful refusal to consummate, though if it caused injury to the wife's health it might amount to legal cruelty. His Lordship therefore granted the wife a decree nisi of divorce on the ground of cruelty, though he dismissed her petition for nullity.

Universities and Colleges

UNIVERSITY OF SHEFFIELD

The following appointments were made at a meeting of the University Council on June 18: *Full-time Medical Officer for the Student Health Service*, P. W. W. Gifford, M.B., Ch.B. *Full-time Assistant Lecturer in Pathology*, B. E. Heard, M.B., Ch.B. *Part-time Tutor in Obstetrics*, S. J. Barr, M.B., Ch.B., M.R.C.O.G. *Part-time Assistant Tutor in Obstetrics*, T. Smith, M.B., Ch.B. Glas., F.R.C.S. Ed., F.R.F.P.S.

The Council received the resignations of Dr. G. B. Oliver (Honorary Lecturer in Industrial Medicine), Mr. M. F. A. Woodruff (Tutor in Surgery), and Dr. G. L. Hermitte (Lecturer in Histology) and thanked them for their services to the University.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

The Faculty of Dental Surgery of the Royal College of Surgeons of England has arranged a series of lectures on anatomy, applied physiology and pathology in their application to dental surgery to be given at the College (Lincoln's Inn Fields, London, W.C.) on Mondays to Fridays, from July 5 to 30, at 5 p.m. and 6.15 p.m. each day. The Faculty also announces a series of lectures on general, oral, and dental surgery to be given at the College on Mondays to Fridays, from Sept. 6 to Oct. 1, at 5 p.m. and 6.15 p.m. each day, except on Sept. 7 and 10 (6.15 p.m. only) and Sept. 16 and 22 (5 p.m. only). The admission fee for each course is £12 12s. (Fellows and Members and Fellows and Licentiates in Dental Surgery of the College will be admitted for £10 10s.) Admission cards may be obtained from Mr. W. F. Davis, secretary of the Faculty of Dental Surgery.

The following lectures will be delivered at the College (Lincoln's Inn Fields, London, W.C.), at 5 p.m. on each day: July 1, Hunterian Lecture by Prof. John Loewenthal, "Treatment of Intractable Ulceration of the Leg, with special reference to Streptomycin"; July 8, Surgery Lecture by Dr. Richard B. Cattell (Surgeon, Lahey Clinic), "Carcinoma of the Pancreas"; July 16, Charles Tomes

UNIVERSITIES AND COLLEGES

Mr. Wilson added that the National Research Development Corporation would work at all times in close co-operation with the Board of Trade, with the Government production departments generally, and with the Medical Research Council and other scientific bodies. It would have a close relationship with existing experimental stations, and would help to speed up the implementation of the fundamental research undertaken in the Government departments and the universities.

After a brief discussion Mr. BELCHER replied for the Government and the Bill was read a second time without a division.

FACTORIES BILL

the subject of an annotation

Mr. ISAACS

After a brief discussion
ment and the Bill was read

[illegible]

ment and the

FACTORIES Bill was the subject of

The new Factories Bill was introduced in our issue of April 10 (p. 698).

Moving the Second Reading on June 11, Mr. Isaacacs said the purpose of the Bill was to extend the medical examination to all young persons entering factory employment and to provide for re-examination at least once a year. These clauses were intended to bring British law into line with the International Labour Convention of 1946. The Government was not in a position to adopt that Convention, but intended to introduce legislation gradually. Clause 6 dealt with the provision of seats in factories. Clause 7 changed the name of "examining surgeon" to "appointed factory doctor" and altered in some degree the manner of his appointment. Mr. Isaacacs held it was better to use the word "doctors." In many cases factories had fully employed doctors for duties which were not covered by the Act. The Ministry of Labour wished to see these doctors more widely used, but doubted whether it could legally appoint them as examining doctors. The Ministry was aware that it was thought the firm's doctor was less likely than an outside doctor to give a certificate that he had the complete confidence and decisions of factory doctors regard to the appointment and decisions of factory doctors. If that could not be got, half their value was lost. Clause 12 gave power to make health or safety regulations about dangerous equipment, such as fire extinguishers, which were not in use in a manufacturing process. A complete, comprehensive industrial medical service could not be established at the moment. More suitable doctors were required before that could be done, but the training of doctors was receiving a new slant in this direction and a powerful association of medical men had banded together to encourage this work.

The debate was adjourned.

When the Report Stage of the Representation of the People Bill was in the House of Commons on June 11, 1948, the Government's proposal for the representation was rejected by a majority of 100.

When the Report Stage of the Representation of the People Bill was taken in the House of Commons on June 14, 1911, the Government's proposal for the extension of the franchise was rejected by 217 to 174. The debate was adjourned.

DEVELOPMENT OF INVENTIONS BILL

University Seats.—When the Report of the Committee on the University Seats of the People Bill was taken in the House of Commons, a proposal to retain university representation was rejected by 88 to 82.

Medical Regulations.—The National Health Service (General Medical Councils) (Scotland) Regulations, 1948, were laid before the House of Commons on June 15, as were the Medical and Dental (Scotland) Regulations, 1948, and the Medical and Dental (Scotland) Regulations, 1948, and the Medical and Dental (Scotland) Regulations, 1948.

N.H.S. Regulations, 1948.—The National Health Service Executive Council, 1948, presented to Parliament on June 15, 1948, and the National Health Service Regulations, 1948, and the National Health Service Board Financial Regulations, 1948, the National Health Service (Supplementary Ophthalmic Services) Regulations, 1948, on June 16 and the National Health Service (Dissolved Authorities) Regulations, 1948, on June 17.

National Insurance and N.H.S.—Major TUFTON-BEAMISH asked
 on June 17 how far persons who defaulted with their subscriptions
 to the National Insurance General Scheme or to the Industrial
 Injuries Insurance would still receive the full scale of medical ser-
 vices provided under the Health Act after July 5. Mr. BEVAN
 answered that entitlement to the health service did not depend on
 contributions at all.

Quinquennial Reports on National Insurance Scheme.—Provision
 in the National Insurance Act, 1946, for quinquennial reports
 on the financial condition of the National Insurance Agency or
 otherwise on the operation of the scheme was referred to the
 Treasury, and the Treasury will

Quinquennial Reports on National Insurance Scheme.—Provision is made in the National Insurance Act, 1946, for quinquennial reports by the Government Actuary on the financial condition of the National Insurance Fund, and on the adequacy or otherwise of the operation of the scheme. These reports are to be made to the Treasury, and are to be laid before Parliament. The first Interim Report will cover the period from July 5, 1948, to March 31, 1950.

No. 23

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended June 5.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland. Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland. A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales, London (administrative county), will no longer be published.

‡ Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales, London (administrative county), are combined.

|| Includes puerperal fever for England and Wales and Eire.

EPIDEMIOLOGICAL NOTES

Travellers to Japan

The following are amended instructions about the inoculation and vaccination certificates required from travellers entering Japan. (1) Vaccination against smallpox and typhoid fever within the preceding twelve months. Persons arriving from an epidemic smallpox area, however, may be required to show evidence of a successful vaccination within the preceding six days. (2) Other special immunizations may be required as deemed necessary by competent quarantine authorities on the basis of actual or threatened epidemics in Japan or to prevent the introduction of epidemic disease into Japan. (3) Person arriving without the required certificates will be given the necessary vaccinations and placed under observation or surveillance for a sufficient period to determine their freedom from these diseases.

These regulations do not apply to allied personnel associated with the occupation forces of Japan, for whom immunization against smallpox, typhoid-paratyphoid, typhus, and cholera are required, in addition to diphtheria immunization for children under 15 years of age, unless they are Schick-negative.

Discussion of Table

In England and Wales a decreased incidence was recorded for measles 2,644, acute pneumonia 100, and dysentery 27, while an increase was reported for scarlet fever 331 and whooping-cough 122.

The largest decreases in the notifications of measles were Warwickshire 457, London 316, Essex 227, Surrey 221, Middlesex 221, Lancashire 181, and Durham 167. The returns for acute pneumonia showed a small fall in all areas except Yorkshire and the northern counties. The increased incidence of scarlet fever was mainly contributed by the northern half of the country; the largest increases were Yorkshire West Riding 45, Lancashire 35, Staffordshire 26, and Durham 26.

Only small fluctuations occurred in the local trends of diphtheria; one-seventh of the total cases were notified in Liverpool C.B. The only variations of any size in the local return of whooping-cough were increases in Lancashire 58 and Kent 54.

Notifications of dysentery were the lowest for the present year. A new outbreak of dysentery affecting 11 persons was notified from Essex; the other large returns were Lancashire 24, London 18, and Yorkshire West Riding 11. The largest return of poliomyelitis were Yorkshire West Riding 5, London 4, Middlesex 4, and Lancashire 3.

In Scotland decreases were recorded in the notification of scarlet fever 19 and measles 15, while the notifications of dysentery increased by 21. The rise in the incidence of dysentery was due to an increase in existing outbreaks; the largest return was Glasgow 33.

In Eire the notifications of measles increased by 23 and those of whooping-cough decreased by 21. Cases of diarrhoea and enteritis reached the low level of 12, of which 9 were notified in Dublin C.B. The increased incidence of measles was fairly general throughout the country.

In Northern Ireland the incidence of measles remained at the level of the preceding two weeks. An increase of 13 was recorded in the notifications of scarlet fever.

Quarterly Returns for Northern Ireland

During the fourth quarter of 1947 the births were equivalent to a rate of 20.5, being 1.3 below the rate for the December quarter of the preceding year. The infant mortality rate was 59 per 1,000 registered births and was 6 above the rate for the preceding fourth quarter but 6 below the average of the corresponding quarters of the five preceding years. Maternal mortality was 1.9 per 1,000 births and was 0.7 below the five-year average. The general death rate was 11.1 per 1,000 and was 1.4 below the average of the preceding five December quarters. Deaths under two years attributed to diarrhoea and enteritis numbered 69. Deaths from pulmonary tuberculosis numbered 165 and from other forms of tuberculosis 33; these were 3 and 27, respectively, below the average of the five preceding fourth quarters.

Quarterly Returns for Scotland

The birth rate for the first quarter of this year was 19.3, being 4.3 below the rate for the corresponding quarter of 1947 but 0.7 above the average of the corresponding quarters of 1943-7. Infant mortality was 51 per 1,000 registered live birth—a new low level, 12 below the value for the March quarter of 1947 and 19 below the five years' average. Maternal mortality was 1.5 per 1,000 births, the lowest rate ever recorded in Scotland, and was 1.5 below the average of the preceding

EPIDEMIOLOGY SECTION

ve first quarters. The general death rate was 13.1 per 1,000. The lowest recorded for the first quarter of any year. This rate was 3.7 below the rate for the first quarter of 1947 and 1.9 below the five-year average. The death rate from all forms of tuberculosis was 78 per 100,000 and that from respiratory tuberculosis was 66; these rates were respectively 5 below and 2 above the five years' average. Deaths from infectious diseases included influenza 53, measles 41, cerebrospinal fever 18, whooping-cough 12, and diphtheria 12.

Week Ending June 12

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,562, whooping-cough 3,298, diphtheria 160, measles 12,225, acute pneumonia 460, cerebrospinal fever 45, acute poliomyelitis 13, dysentery 95, paratyphoid 6, and typhoid 3.

Medical News

Northern Ireland Mental Health Bill

A Mental Health Bill for Northern Ireland has been published. It contains provisions for the prevention, diagnosis, and treatment of mental illness. Emphasis is laid on the making of suitable arrangements for the welfare of patients including after-care. Specialist services will be available at out-patient clinics and will ordinarily be secured through a recommendation made by the patient's own doctor. Persons admitted to mental hospitals will fall into one of two groups. There will be the voluntary patients who know that they need treatment and will apply to obtain it. Patients in the second group will be admitted as "temporary patients" on the recommendation of only one medical practitioner. Treatment in the temporary category may continue for a period of up to two years. When it is found that it is no longer proper to retain a mentally ill person as a temporary patient, steps may be taken to have him certified by a judicial authority as a person of unsound mind.

For the first time in Northern Ireland provision is to be made for mental defectives—defined as persons suffering from arrested or incomplete development of mind which renders them socially inefficient to such an extent that they require care in their own interests or in the public interest. Part 4 of the Bill is concerned with the powers of medical inspectors appointed by the Ministry of Health for the purposes of the mental health arrangements and with other safeguards designed to secure the liberty of the subject.

R.A.M.C. Jubilee Scrapbook

To commemorate the Golden Jubilee of the R.A.M.C. it has issued an illustrated *Jubilee Scrapbook* (Gale and Polden, 2s. 6d.; profits are contributed to the R.A.M.C. War Memorial Fund). The scrapbook is well illustrated with photographs of royalty visiting the R.A.M.C. in peace and war and includes notes and stories of celebrated occasions.

Dentists Reject Health Service

The Representative Board of the British Dental Association, which represents about 8,000 of Britain's 12,000 dentists, met at Birmingham on June 20 and issued the following statement:

"The views expressed at special branch meetings held during last week and the extraordinary general meeting in Birmingham on Saturday showed clearly that the members of the association are solidly behind the present policy of the association. The members are profoundly dissatisfied at the complete refusal in connexion with to grant any of the association's basic principles in which the health service, at the hurried and incomplete way in which the remuneration negotiations were carried through, and the lack of security in the present position by which a whole-salaried service can be introduced by regulation alone. The letter to be sent to members will point out that, although the Acts have been passed, the National Health Service cannot be successful without the willing co-operation of the majority of their members will not willingly go into the Service."

Dentists Say Yes

The incorporated Dental Society and the Public Dental Service Association are leaving it to their members to decide individually whether or not to enter the Service. They state that there is nothing in the Act or Regulations to justify their recommending dentists not to join.

Pharmacists Accept Health Service

The National Pharmaceutical Union has stated that with a few exceptions pharmacists will serve under the National Health Service.

Opticians to Enter Service

The joint emergency committee representing the opticians has advised them to enter the supplementary ophthalmic scheme of the N.H.S. on July 5, though the Minister's terms are not entirely adequate. The Minister's decision that people must obtain a certificate from a doctor before visiting an optician for the first time, instead of going direct, is accepted by the Committee under protest. The Committee considers that the remuneration is too low, but has been assured that the matter can be taken up through the Whitley Council.

Empire Cancer Campaign

A delegation from the British Empire Cancer Campaign left England on June 24 to visit Canada and the U.S.A. until Aug. 4. Its members are Lord Horder, Sir Stanford Cade, Prof. F. Dickens, Prof. B. W. Windeyer, Dr. P. R. Peacock, and Captain F. B. Tours, R.N. (ret.). The delegation will discuss recent developments in cancer research with interested organizations.

Conservatives and the Health Service

Sir Hugh Lucas Tooth at the Ladies Carlton Club on June 19 said that both Conservatives and Socialists promised a comprehensive health service at the last election, the Conservatives emphasizing the need for retaining tradition, the Socialists for centralization. The Conservatives opposed the National Health Service Bill because they regarded it as hopelessly over-centralized. Now that the Act was on the statute book the position was changed. The Conservatives had not and would not sabotage the will of Parliament; indeed, they had done all they could to bring about an agreement, fairly arrived at, between the Minister and the doctors so as to make the Act as successful as possible.

Harveian Society Dinner

The Harveian Society of London held the Buckston Browne dinner on June 17, the President, Mr. E. G. Muir, F.R.C.S., being in the chair. The health of the Society was proposed by the President of the Royal College of Obstetricians and Gynaecologists, and responded to by Mr. Muir. Lord Balfour of Burleigh and Sir Frederick Sellers responded to the toast of the guests, which was proposed by Mr. Rodney Smith, F.R.C.S. The Harveian Society was founded in 1831 under the name of the Western London Medical Society, which was changed within a month to the present title. It was not until 1856 that the members of the Society dined together. The late Sir Buckston Browne established a fund to enable men to dine together once a year, and also made it possible for the Society to offer a prize and medal for the best essay on a subject of medical interest selected by the Council.

Ambulance by Radio

The first wireless-controlled ambulance service in Britain was started in the Yorkshire West Riding on May 24. There are four ambulances fitted with short-wave sets and the master station is at Birkenhead. If the service is a success it will be expanded to cover the whole county.

Dr. C. Gray Imrie

The honorary degree of D.Sc. has been conferred on Cyril Gray Imrie, M.D., F.R.C.P., honorary physician to the Sheffield Royal Hospital, by the University of Western Ontario, from which he graduated in 1911.

Committee on Psychiatry

Psychiatrists in the North-west Metropolitan Hospital Region have elected an advisory committee to represent various aspects of the psychiatric service. The following are the members: *Mental Hospitals*: Dr. A. C. Dalzell, Dr. J. B. S. Lewis, Dr. S. A. MacKeith (deputy chairman). *Mental Deficiency*: Dr. N. H. M. Burke, Dr. J. H. Watkin. *Adult Out-patient Clinics*: Dr. E. A. Bennet, Dr. B. C. M. Gilson, Dr. J. D. Sutherland (honorary secretary). *Child Guidance Clinics*: Dr. J. Bowlby (honorary treasurer). *Dr. W. Moodie*, Dr. D. W. Winnicott. *Teaching Hospitals*: Dr. N. McDiarmid. *General*: Dr. J. Rickman. *Representative of Psychiatrists*: Dr. D. Odum, Dr. J. L. Ferard. *Professional Social Workers*: Miss M. L. Williams. Further information may be obtained from the honorary secretary, at 2, Beaumont Street, London, W.1.

Commonwealth Fund Fellowships

The following members of the medical profession have been appointed to Fellowships tenable by British graduates in American universities for one year from September, 1948, by the Committee of Award of the Commonwealth Fund Fellowships (35, Portman Square, London, W.1): G. M. Carstairs, M.B., Ch.B.; R. B. Hunter, M.B.E., M.B., Ch.B.; M.R.C.P.Ed.; R. W. Riddell, M.B., B.S., M.R.C.P.Ed.; G. A. Smart, M.D., M.R.C.P.

Dr. Chuni Lal Katial

On June 8 the Freedom of the Borough of Finsbury was granted to Chuni Lal Katial, M.B., B.S., D.T.M. Dr. Katial was Mayor of Finsbury in 1938-9 and was a first-aid medical officer throughout the war. He is leaving Finsbury to become Director of all India's industrial health services.

Air Marshal Sir Harold Whittingham

Air Marshal Sir Harold Whittingham, B.O.A.C.'s Director of Medical Services, has flown to Toronto to attend meetings of the Airline Medical Directors Association, the Aero Medical Association, and the Medical Panel of the International Air Transport Association.

30-Million Volt Synchrotron

Following their operation of the world's first synchrotron in 1946, the Electronics Group of the Ministry of Supply's Atomic Energy Research Establishment has now made a larger machine, producing 30-million volt x rays. Details of the synchrotron were given in an annotation in the *Journal* of March 20 (p. 554).

Wills

Mr. John James Robb, of Dundee, left £37,870. Dr. John Braithwaite, formerly in practice in Boston, Lines., left £53,299; Dr. Edward Stainer, of Great Missenden, £12,706; Mr. Ernest Arnold Hodgson Hindhaugh, of Liverpool, £9,482; and Lieut.-Col. Joseph Hulbert, late I.M.S., £10,460.

COMING EVENTS**Medical Records Officers**

The Association of Medical Records Officers held a week-end school at Bristol Royal Infirmary on May 29-30 under the presidency of the Infirmary's House Governor, Mr. S. C. Merivale. Similar courses will be held at St. Bartholomew's Hospital, London, for the N.E. Metropolitan Region on June 26-27 and at the Manchester Royal Infirmary for the Manchester Region on July 17-18. It is hoped to hold further courses during the year at Cardiff, Liverpool, Leeds, London, Newcastle, and Sheffield.

Kettle Memorial Lecture

Prof. W. D. Newcomb, M.D., F.R.C.P., will deliver the Kettle Memorial Lecture on "Bone Growth and Absorption" in the lecture theatre of the Inoculation Department of St. Mary's Hospital Medical School, Praed Street, London, W., on Tuesday, June 29, at 5 p.m. All medical practitioners and medical undergraduates are invited to attend the lecture.

Nurses Conference

The Royal College of Nursing will hold its annual meeting and conference on June 30 to July 3. The annual general meeting will be at 3 p.m. on July 1 at the Central Hall, Westminster, and the professional conference on "The Nurses in the Social Order" will follow at 8 p.m. Speakers include Miss K. S. Armstrong, former editor of the *Nursing Times*, and Miss M. B. Powell, Matron at St. George's Hospital.

Cameron Prize Lecture

Prof. E. B. Astwood, M.D., C.M., Ph.D., Research Professor of Medicine, Tufts Medical School, Boston, Mass., U.S.A., will deliver the University of Edinburgh Cameron Prize Lecture for 1948 in the Anatomy Lecture Theatre, University New Buildings, Teviot Place, Edinburgh, on Friday, July 2, at 5 p.m. His subject is "The Use of Radioactive Iodine in the Study of Thyroid Function in Man." All students and graduates are invited to attend the lecture.

Society of Medical Officers of Health County Borough Group

The annual meeting and conference of the County Borough Group of the Society of Medical Officers of Health will be held at Aberdare Hall, Cathays Park, Cardiff, on Friday, Saturday, and Sunday, July 2, 3, and 4, under the presidency of Dr. J. Greenwood Wilson (Cardiff). The speakers will be Dr. E. K. Maedonald (Leicester), on "The fragments that remain . . ."; Dr. Charles M. Fletcher, Director of the Medical Research Council's Pneumoconiosis Research Unit; Sir Frederick Rees, Principal, University College of South Wales and Monmouthshire, Cardiff, on "Post-war Planning"; Dr. D. A. Williams (Llandaff), Mr. D. B. E. Foster (Ponarth), and Miss Mary Davies (health nurse, Cardiff Health Department), on "Follow-up of Ex-hospital Patients"; and Dr. W. G. Patterson, Senior Administrative Medical Officer, Newcastle-upon-Tyne Regional Hospital Board, on "The Regional Hospital Board and the Medical Officer of Health." The Lord Mayor of Cardiff has accepted an invitation to join the group at its inaugural dinner on the evening of July 2 and will entertain them to luncheon. It is hoped at Cardiff Castle, on July 3. The vice-president and honorary secretary of the group is Dr. R. M. Galloway, 10, Stapleton Avenue, Haver, Bolton, Lancs.

Oxford Graduates' Medical Club

The summer dinner of the Oxford Graduates' Medical Club will be held at Christ Church, Oxford, on Friday, July 16, at 7 for 7.30 p.m., when the chair will be taken by Prof. A. W. M. Ellis D.M., F.R.C.P. All men who are Oxford graduates, studying or practising medicine, are members of the club, and it is hoped that there will be a good attendance at this the first post-war dinner. Accommodation is restricted, making it impossible to allow guests on this occasion. The joint honorary secretary of the club Mr. E. A. Crook, M.Ch., F.R.C.S. (149, Harley Street, London, W.1), asks those who intend to be present at the dinner to let him know by July 1 at the latest; he would also be glad of the permanent addresses of all members. The cost of the dinner is 30s., inclusive of wine, and day dress will be worn.

SOCIETIES AND LECTURES**Monday**

INSTITUTE OF LARYNGOLOGY AND OTOLGY, 330, Gray's Inn Road, London, W.C.—June 28, 5.30 p.m. "Medical and Surgical Treatment in Relation to the Physiology of the Nose," by Dr. Arthur Proetz (St. Louis, U.S.A.). Followed by questions and discussion.

Tuesday

EDINBURGH POSTGRADUATE BOARD FOR MEDICINE.—At Edinburgh Royal Infirmary, June 29, 5 p.m. "Changing Concepts in Therapeutics," by Prof. D. M. Dunlop.

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—June 29, 5 p.m. "Pitfalls in Skin Therapy," by Dr. H. Gordon.

ST. MARY'S HOSPITAL MEDICAL SCHOOL, Praed Street, London, W.—In Lecture Theatre of the Inoculation Department, June 29, 5 p.m. Kettle Memorial Lecture: "Bone Growth and Absorption," by Prof. W. D. Newcomb.

Thursday

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, London, W.C., July 1, 5 p.m. "Treatment of Intractable Ulceration of the Leg, with Special Reference to Sireptomycin," Hunterian Lecture by Prof. John Loewenthal (University of Manchester).

Friday

EDINBURGH UNIVERSITY.—In Anatomy Lecture Theatre, University New Buildings, Teviot Place, Edinburgh, June 29, 5 p.m. "The Use of Radioactive Iodine in the Study of Thyroid Function in Man," Cameron Prize Lecture by Prof. E. B. Astwood, Research Professor of Medicine, Tufts Medical School, Boston, Mass., U.S.A.

BIRTHS, MARRIAGES, AND DEATHS**BIRTHS**

Blainkin.—On June 12, 1948, at 12, Avenue Road, London, N.W., to Dr. Lillian Rivlin, wife of George Blainkin, a daughter—Lynne.
Crane.—On June 11, 1948, to Dr. Nest Crane (née Llewellin), wife of Dr. J. E. Crane, Carmarthen, a daughter.
Ingills.—On June 10, 1948, to Joan (née Dobson), wife of Dr. A. Ingills, a son.
McCoy.—On June 14, 1948, at Cambridge, to Pauline, wife of John McCoy, M.B., D.P.H., a daughter—Jennifer.
Martin.—On June 16, 1948, in London, to Eileen, wife of Dr. J. D. M. Martin, a daughter.
Morel.—On June 3, 1948, at Barnstaple, N. Devon, to Daphne (née Elmstic), wife of Dr. Mervyn Morel, F.R.C.S., a son—Paul Gordon.
Rudd.—On June 13, 1948, at The Gables Nursing Home, Aylesbury, to Margaret (née Coghill), wife of Dr. Peter Rudd, Winslow, Bucks, a daughter.
Scadding.—On June 17, 1948, in London, the wife of Dr. J. G. Scadding, a son.
Van Essen.—On May 29, 1948, at Guy's Hospital, in Janet C. Van Essen (née Trotter), M.B., Ch.B., wife of William M. Van Essen, F.R.C.S.Ed., of 14, Oakhill Road, Beckenham, Kent, a daughter—Morna Janet, a sister for Christopher.

DEATHS

Arkle.—On June 16, 1948, at "Marfield," Town Row, West Derby, Liverpool, Alexander Septimus Arkle, M.R.C.S., L.R.C.P.
Baker.—On June 19, 1948, at 2, Robertson Road, Bournemouth, Nugent Brander Baker, L.R.C.P.&S.Ed., L.R.F.P.S.Glas.
Barnes.—On June 17, 1948, at St. Albans, Heris, Augusta Schram Barnes, M.B., Ch.B.Ed., aged 36.
Edwards.—On June 17, 1948, at Westgate House, Leominster, Harford Norman Edwards, M.R.C.S., L.R.C.P.
Edwards.—On June 14, 1948, at Ainsdale, Percy Edwards, O.B.E., M.R.C.S., L.R.C.P., L.S.A., formerly of Liverpool, aged 84.
Mott.—On June 11, 1948, at The Woodlands, Hurnway, Christchurch, Hants, Georgiana Alexandra, widow of Sir Frederick Walker Mott, K.B.E., Hon.L.L.D., M.D., F.R.C.P., F.R.S.
Patten.—On June 13, 1948, Charles Joseph Patten, M.D., Sc.D., Emeritus Professor of Anatomy, Sheffield University, of Leyton House, Hale Road, Farnham, Surrey.
Porteous.—On June 12, 1948, at Douglas, Isle of Man, Edward John Porteous, M.B., Ch.B.Ed.
Salisbury.—Recently, Harold Kenneth Salisbury, M.R.C.S., L.R.C.P., of Woodstock Road, Redland, Bristol.
Sharp.—On June 19, 1948, at Struan Lodge, Musselburgh, Midlothian, James Sharp, M.B., Ch.B.Ed.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

General Tonics

Q.—In answer to a question on early signs of rheumatoid arthritis (April 17, p. 770) reference is made to treatment by "general tonics, especially cod-liver oil." What are general tonics? Is cod-liver oil one? If so, what is the evidence for this, and how is it thought to act in the case of a patient who without it is already receiving an adequate diet? Extract of mull and cod-liver oil, and also Parrish's food, are often prescribed for children to improve their general health. What benefit is obtained from such treatment, and how is it produced?

A.—Cod-liver oil had been known to have special value in respiratory infections for many years before vitamins were heard of, and there is no evidence that the value of the oil in respiratory infections (that is, in making children more resistant to bronchitis and pneumonia, and in improving those suffering from chronic bronchitis) is due to vitamins. Cod-liver oil contains a relatively large amount of iodine, and this may play a part. Aside from respiratory infections it is not easy to find precise evidence that cod-liver oil is a tonic. Its content of iodine may make it of value in conditions in which there is mild thyroid deficiency, of which rheumatoid arthritis is sometimes considered to be one. Unless an "adequate diet" contains a good deal of sea-fish it may be inadequate in its content of iodine. Mild thyroid deficiency can also be remedied by giving small doses of thyroid. The dose can be increased until there is a rise in the pulse rate or until the patient complains that he feels nervous or irritable.

General tonics used to include Parrish's food or Easton's syrup. These acted as bitters stimulating a greater flow of gastric juice and thus increasing the appetite. When the patient's appetite improved he felt stronger. It is not likely, however, that those with rheumatoid arthritis will do better if they eat more. The only other form of tonic which can be cited is the administration of large doses of vitamin B₁ (aneurin). Tablets containing 25 mg. given four times a day may be beneficial in lumbago. Why, is not known.

High Diastolic Pressure in the Elderly

Q.—In what circumstances can a good prognosis be given when the diastolic pressure is 130 mm. Hg or above in patients over, say, 50 years of age?

A.—One can never give a good prognosis in a patient whose diastolic blood pressure reaches 130 mm. Hg or above unless it has been induced by temporary extreme exertion of emotion. Even in such cases its occurrence would suggest a pathologically raised blood pressure in normal circumstances. In cases due to possibly removable causes, such as unilateral renal disease, coarctation of the aorta, or adrenal tumour, operation would be too late to avoid permanent and perhaps progressive damage to the kidneys and cardiovascular system. Indeed, in the case of coarctation the time for operation would have been long past. Factors mitigating somewhat the gravity of the prognosis would be a good response to treatment, a female as opposed to a male patient, the absence of family history, and the absence of angina pectoris or congestive heart failure. The less enlarged the heart and the fewer the secondary changes in the kidneys and retinae the better; but, whatever other findings there are, the outlook cannot be anything but gloomy.

Paludrine in Malaria

Q.—What dose of paludrine do you advise for (a) curative and (b) prophylactic purposes for a child aged 10? From which points of view, is paludrine more effective than the older remedies or not?

A.—(a) If the malaria is due to *Plasmodium falciparum* 0.1 g. of paludrine twice daily for 14 days should not only control the attack but may completely eradicate the infection from the

child—depending on the strain of *P. falciparum*. If the malaria is due to any other species of malaria parasite no short-term treatment can be guaranteed to eradicate the infection completely. In such cases 0.1 g. of paludrine twice daily may be given until the acute attack is controlled, and thereafter 0.1 g. weekly may be taken for 6 to 12 months in the hope that by this time the infection will have disappeared spontaneously. These relapsing types of infection, however, are better treated by the initial combination of a schizonticidal drug to control the acute symptoms and some such compound as pamaquin or pentaquine, which by a devitalizing action on exo-erythrocytic parasites make relapse less likely. (b) 0.1 g. of paludrine every day.

With African strains of *P. falciparum* fever has occurred even when daily suppressive doses of paludrine were being taken, and, in addition, in the control of acute attacks paludrine is slower and less effective than mepacrine. Its relation to the possible onset of blackwater fever has not yet been determined. At present in the treatment of acute attacks mepacrine is probably more satisfactory because it is known not to precipitate the onset of blackwater fever following infection with African strains of *P. falciparum*.

Immunization against Scarlet Fever

Q.—What is the present position with regard to active immunization against scarlet fever?

A.—Active immunization against scarlet fever requires 4 to 5 weekly subcutaneous or intramuscular injections of streptococcal toxin increasing in dosage from 500 skin-test doses until a total of 80,000 to 100,000 S.T.D. has been given. There is often some local reaction with redness and swelling of the arm, and susceptible children occasionally have a generalized rash with fever (miniature scarlet fever). All that is effected by such a course of inoculations is an antitoxic immunity which will inhibit formation of the scarlatinal rash but which does not protect the child against infection by *Str. pyogenes*. Scarlet fever is now a mild disease which attacks less than 10% of the child population. An affected child can be safely nursed at home and can be treated effectively with penicillin and antitoxin, so that there seems no point in recommending active immunization in a private family under present conditions.

Colour Reaction due to Sulphones

Q.—What is the nature of the colour reaction stated to be given by sulphones in patients suffering from leprosy? Would anaesthetics of the procaine series be likely to produce similar colour reactions?

A.—A colour reaction develops in patients treated with sulphones such as diasones, which is used in leprosy. It is a blue coloration of the skin due to a dye which is formed in the body from the sulphone and which circulates in the blood. It is not a true cyanosis, and the oxygen-carrying power of the blood is not diminished as it is, for example, when methaemoglobin is formed. There is no reason to suppose that anaesthetics of the procaine series would produce similar colour reactions.

Overlapping Rib

Q.—Can the lowest rib overlap the one above? A middle-aged man complains of occasional "overlapping" of the lowest rib on the right side, which he says is the result of a contusion in this spot sustained in a motor-car accident fifteen months ago. He suffers great pain when this overlapping (or underlapping) occurs. X-ray examination has revealed no bone injury or deformity. Is this condition possible? If so, is it attributable to the injury and is it likely to be permanent?

A.—It is difficult to give a direct answer to this question without an examination of the patient. It can be stated, however, that the phenomenon described—of "overlapping" of the lowest rib—is not common. Sometimes after injury there is a disruption of the lower rib cartilages, and one may override or underlap its neighbour during deep respiration or when bending forwards. Usually the patient can feel and hear a "click," which is painful. As a rule in genuine lesions of this type the doctor can also feel one cartilage slipping on another. There is a great tendency for psychologically unstable patients to

make a habit of producing the "click," as they also do when clicks occur elsewhere—e.g., the jaw, the shoulder, the hip. It is rarely necessary to go to the length of exploring and excising a portion of the affected cartilage.

"Chill on the Liver"

Q.—What is the underlying pathology of a "chill on the liver"? A patient has on four occasions within the last 15 years complained of attacks of anorexia, nausea, and generalized abdominal discomfort. His stools were putty coloured, but there was no clinical evidence of jaundice. Each attack lasted three or four days and always started a day or so after exposure to damp and cold.

A.—Not only is the pathology of "chill on the liver" unknown but the term itself is employed to describe various dissimilar functional disturbances. It is often used by laymen, but in no clearly defined sense. Essex Wynter (*Minor Medicine*, 1907) employed it to mean an attack in which there was complaint of pain or discomfort in the right hypochondrium with anorexia and constipation; he postulated transient engorgement of the liver. Leonard Williams (*Minor Maladies*, 1919) understood by a "chill on the liver" a febrile attack with myalgia. In the above instance a third meaning is given to the expression; here the symptomatology certainly suggests an ephemeral disturbance of liver function. An isolated bout of this nature might well be taken for an abortive attack of infective hepatitis; so-called biliary dyskinesia might be responsible. Disturbances of this kind are not rare in patients with hepatic cirrhosis, and occur also in those subject to migraine.

Hereditary Trophoedema

Q.—Is there any cure or beneficial treatment for hereditary trophoedema?

A.—Hereditary trophoedema, or Milroy's disease, can be a grievous affliction, especially if bilateral. The usual treatments for lymphoedema are indicated—sleeping with the foot of the bed well elevated and wearing elastic stockings in the daytime. Sometimes elastic bandages are stronger and more effective than the stockings. If the swelling cannot be brought under control by these supports then the constant wearing of glue bandages (Unna's type) is indicated. This is a great nuisance but is preferred by the patient to the unsightly swelling, although bathing is made impossible by the bandages. Radical operations of the Sistrunk type are worth while in the severer cases; large areas of redundant skin and all the deep fascia possible are removed after completely reducing the leg by rest and posture, combined if possible with the use of the "pneumassage" machine devised by Hunt. An interesting case of Milroy's disease was described in detail by Braham and Howells in the *Journal of May 1* (p. 830).

Dreams of Persons Born Blind

Q.—Is anything known about the dreams of individuals born blind? Do these people dream and, if so, what is the content of their dreams?

A.—People born blind have very profuse dreams; and as one has just expressed it to the writer, "Their dreams are just as mad as those of other people." The question is presumably based on the supposition that dreams are visual, and that as the individual born blind has never had the capacity nor the material for visualization he will not dream. But dreams of a non-visual kind are not uncommon—for example, kinaesthetic dreams (floating, etc.), and auditory dreams (conversation or sentences). We should therefore expect those born blind to dream, though not visually. (Some claim that they have visual dreams, just as some claim that they have a perception of colour, but a description of their experience suggests something very different from that of those with sight.) They dream in terms of their every-day experiences and by means of their other senses. Indeed, those who have seen but have lost their sight may have visual dreams for a time, but tend to lose them in favour of auditory and other sensations. It seems that we dream in terms of the sense most used by us in our accommodation to the outside world—with most people this is the visual sense; to the blind it is usually auditory, olfactory, or tactile, and those born blind therefore appear to dream most commonly

in these terms. Helen Keller (who was not, however, born blind) had a frequent nightmare of walking endlessly round a curved object (tactile and kinaesthetic), not knowing where it goes or in what direction. She also had dreams of committing murder to save the lives of others.

NOTES AND COMMENTS

Gifts from America.—Dr. H. J. FENN, 95, Shooters Hill, London S.E.18, writes: I wish to bring to your notice the existence of the Amateur Radio International Friendship Association. This organization, which is typical of the "Ham Spirit" which pervades the world of amateur radio, resulted from the chance contact between an American and a British amateur, both of whom were recovering from illness. The American, wishing to celebrate the contact, asked for details of two persons or families who were hard hit by sickness, the war, or old age, and sent them each a gift parcel. Further he sold the idea to others, and the Association came into being. The situation now is that there are more would-be donors than recipients. It would be appreciated if members of the B.M.A. could spare a little time to assist in furthering this work by submitting details of genuine cases of hardship caused by sickness, old age, war conditions, or physical disability. It would be a help if members used their headed notepaper and typed the following details: full name, age, sex. In the case of children, state whether normal, over- or under-size, since clothing may be sent. Full postal address. Additional details required are religious affiliations; fraternity associations, i.e., Masonic, Rotarian, etc. Usual occupation. Hobbies, if any. Any other useful data. It should be borne in mind that donors often prefer to help members of the same Church, or person of the same name or occupation, or who seem to have the same tastes. If possible an indication of the cause of hardship should be given. Every effort is made in America to place details of each case with a donor who is likely to have some community of interest with the recipient.

Pitressin Tannate.—Parke, Davis and Company point out the statement that pitressin tannate is "water-soluble" (June 1, p. 1120) is incorrect. This should have read "water-insoluble."

INCOME TAX

All inquiries will receive an authoritative reply but only a selection can be published.

Attending Scientific and/or Council and Committee Meetings

The question raised is not capable of a simple answer; whether such expenses can be deducted for income-tax purposes depends on the circumstances of the member and the purpose served by his attendance at meetings at the institute in question.

I. Cases in which the earnings of the member are derived from employment, etc., and are therefore assessable under Schedule E.

The statutory rule requires that to be deductible expenses must be incurred wholly, exclusively, and necessarily in the performance of the duties of the employment. It may be assumed, we think, that an employee could not successfully contend that his attendance at such meetings was part of the duties required by the terms of his service contract. Accordingly the expense of attendance would not be legally deductible.

II. Cases where the earnings are assessed under Schedule D.

The statutory rule is less rigid, and it is the practice in such cases to admit as deductible such expenses as the maintenance (not the building up) of a medical reference library on the ground that it is in essence the maintenance of the "tools" of the practitioner. A natural extension of such allowances is to permit the cost of attending lectures, etc., the purpose of which is similar, i.e., to keep the practitioner's knowledge up to date. (This, however, would not extend to a widening and substantial improvement of professional knowledge, e.g., to attending a special course in tropical medicine or public health.)

Applying these considerations to the question, we conceive that inspectors of taxes might legitimately allow the cost incurred by a general practitioner of attending a meeting the purpose of which was to afford further professional knowledge, but refuse it if the purpose was to advance or protect the general interests of the profession.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY JUNE 26 1948

HEARD AT HEADQUARTERS

Charities Still Buoyant

It is worthy of note that the amounts received by the B.M.A. for the various medical charities during the first three months of this year were at almost exactly the same level as for the corresponding period in 1947. The amount received from January to March last year, taking earmarked and non-earmarked subscriptions together, was £7,000, and this year it was £6,987. During the first three months of this year there was an unprecedented crisis in the medical profession: large numbers of practitioners must have felt insecure in their personal position, and must have survived their commitments with more than ordinary concern, so that there would be a great temptation to let charitable appeals await more settled weather. Yet the amount subscribed was practically the same as before, and the subscriptions to the two principal charities—the Royal Medical Benevolent Fund and Epsom College—were larger than usual. A member suggested at the last Council meeting that a well-designed Christmas card showing the B.M.A. building should be produced in good time for next season and sold for the benefit of medical charities. Another member suggested that a more interesting picture might be a group of the members of the Council in session, but the member who had made the original suggestion replied that he was anxious to ensure that there was a profit.

Ministry of Education Circular 102

The special committee of the Association which was set up last year to consider the question of fees for treatment of school-children has had to report that it is unable to make further progress. Certain proposals were put forward by the Association for a revision of the fees as set out in the Ministry's circular 102 in respect of the treatment of school-children at voluntary hospitals; a slight modification was obtained, but its effect was quite small; and the Ministry of Education's reply to repeated representations has been that if the Association wishes to pursue the matter the only course is to enter into negotiations with the local authority associations, when the Ministry would consider the result. A tentative approach was made to the local authority association mainly concerned, but it was learned that that body would not feel disposed to negotiate revision of fees about which it had not been consulted in the first place and which it had accordingly accepted only under protest.

Contracts in General Practice

The attention of the Central Ethical Committee has been drawn to a number of difficulties which have recently confronted purchasers of practices and employers of assistants where through lack of foresight their interests have been inadequately safeguarded in their agreements. At a time such as the present, when contracts are being framed hurriedly, it is important that all possible contingencies should be covered. In a number of cases principals have discovered that their previous assistants have been able to return and practise in the locality, and in other cases practitioners have bought practices only to find that the vendor has returned to practise in the locality which he had vacated. Such departure from the traditional standards of ethics is to be deplored and can be safeguarded only by adequate legally enforceable agreements made at the time of transaction.

Complaints Anticipated

Mr. Bevan seems to covet the role of St. Sebastian, to whom, pierced by a thousand javelins, he likened himself at a meeting at the Royal College of Nursing the other day. He expects a flood of complaints directly July 5 is upon us. "I don't know," he told the nurses, "but what I shall not try to go about disguised after July 5. For every mistake you make I shall have to bleed." The National Health Service Act, he said, placed a megaphone at the mouth of every person with a complaint. As time went on, of course, the complaints would dwindle, and perhaps after a season would be transmuted into praises. The National Health Service would eventually no longer be news, for there was no news but bad news. To say that a health service was working smoothly was not news; to bring up scandals and charges of inefficiency was news of the first order. There would come a time when there would be no headlines, no buffetings of the Minister, no questions in Parliament. Meanwhile Mr. Bevan described himself as the central registrar for defects.

No Patchwork for Health Centres

The very name of health centre has a fascination for some people, and probably the greatest surprise they will experience after July 5 is to find the urban landscape very much as before instead of being decorated by 2,000 new buildings functioning as health centres, none of them more than a mile away from the house of anyone who lives in a town. An architect on the staff of the Ministry of Health was questioned on the subject at a recent conference and declared that there was no intention of making health centres out of patched-up buildings. The Minister had made it clear, he said, that in order to get his scheme launched properly health centres must be in new buildings, not existing buildings adapted for the purpose. A private architect on the same occasion also said that it was imperative that health centres should be specially designed. To the British mode of life the health centre is a new creation and calls for a new architectural form. Even reference to America does not reveal much satisfactory information. But the Minister also holds that dwelling-houses must have precedence over health centres and even over maternity homes.

Under the Influence

Convictions for being under the influence of drink while in charge of a car may be expected to be slightly more frequent among doctors than among other classes of the community, not because doctors are more addicted to alcoholic indulgence, but because they are constantly driving cars at all hours of day and night in the course of their occupation. One of the respondents on this occasion had been before the Council on a similar charge 25 years ago, when the then President, Sir Donald MacAlister, as was his wont in every such case, exacted a pledge of total abstinence from him. Sir Donald would never let an erring doctor go away without promising never to touch drink again. The present President takes a different line, believing that the Council ought not to ask for such assurances and ought to judge not according to what a man promises but according to what he performs.

A Ninetieth Annual Meeting

The Metropolitan Counties Branch of the Association held what was described as its ninetieth annual meeting the other day, though in fact the official history of the Association gives the Branch as having been established in 1853. Its formation marks the end of the Association's existence as a provincial

society. With the taking in of the metropolitan counties the Association, so to speak, came to town. The Branch was from the first active in its support of the Association's policy on medical reform, reform of the Poor Law, and reform in the teaching of midwifery. Some great men in Association annals have been presidents of the Branch, and Mr. A. M. A. Moore, the new president, with becoming humility, mentioned the names of some of his predecessors within comparatively recent years, including the late Mr. Bishop Harman, for many years treasurer of the Association, and the late Mr. E. B. Turner, one-time chairman of the Representative Body. Mr. Moore in his presidential address gave an unusually interesting discourse on the anatomy of the hand and foot and some common or less common abnormalities. Owing to a long previous discussion on some business connected with the rules and other matters, the meeting had lasted an hour before the presidential address was reached, but Mr. Moore held his audience for another hour, and made the dry bones live and dance before them.

Field Epidemiology

A lively contribution was made to the proceedings of the Harrogate conference of the Royal Sanitary Institute by Dr. W. H. Bradley, senior medical officer of the Ministry of Health. Dr. Bradley pointed out that, while there had been many outstanding achievements in field epidemiology, there still remained a vast range of infections, "collywobblers, molligrubs," of which very little was known. Epidemiology, he said, was now a job for a team. The days of individualistic study were over, though he hoped that from time to time British medicine might sport a genius like Pickles, a general practitioner who knew how to play a solitary game to the general advantage. But on the whole it was a matter for team work. The great thing to remember was that the first case of infection in any district was the one which mattered most. "I believe," said Dr. Bradley, "the family doctor realizes this as much as the medical officer of health, and I think they should always get together on these occasions and bring in the rest of the epidemiological team." The final high-light which Dr. Bradley projected was a picture of the medical officer of health divesting himself of his committee suit, donning a pair of stout boots, and heading for the field, which promised a greater harvest than the office desk, and he hoped the general practitioner would join him there.

SUPPLY OF VACCINES IN N.H.S.

After July 5 lymph for smallpox vaccination will be available free of charge to medical practitioners in the Service, who should apply for it at the nearest or most convenient laboratory shown in the following list. They will receive officially printed application forms, with prepaid postage.

Birmingham: City Bact. Labs., 150, Great Charles Street, Birmingham, 3. (Telephone: Central 1724.) **Bristol:** Dept. of Preventive Medicine, Whitley Road, Clifton, Bristol, 8. (Telephone: Bristol 38257.) **Cambridge:** Public Health Lab., Dept. of Pathology, Tennis Court Road, Cambridge. (Telephone: Cambridge 55526.) **Cardiff:** Public Health Laboratory, Institute of Preventive Medicine, The Parade, Cardiff. (Telephone: Cardiff 8288.) **Carlisle:** Path. Lab., Cumberland Infirmary, Carlisle. (Telephone: Carlisle 590.) **Carmarthen:** Public Health Laboratory, Penlan Road, Carmarthen. (Telephone: Carmarthen 7271.) **Conway:** Public Health Laboratory, "Bryn Hyfryd," Conway. (Telephone: Conway 2178.) **Derby:** County Offices, St. Mary's Gate, Derby. (Telephone: Derby 47131, Extn. 120.) **Dorchester:** County Laboratory, Glyde Path Road, Dorchester, Dorset. (Telephone: Dorchester 600.) **Exeter:** Public Health Laboratory, 7, Dix's Field, Exeter. (Telephone: Exeter 4550.) **Hereford:** Public Health Laboratory, County Offices, Hereford. (Telephone: Hereford 3071.) **Ipswich:** Public Health Lab., County Lab., Bond Street, Ipswich. (Telephone: Ipswich 51398.) **Leeds:** Bact. Dept., School of Medicine, Leeds, 2. (Telephone: Leeds 20071.) **Leicester:** Public Health Lab., Isolation Hosp., Groby Road, Leicester. (Telephone: Anstey 383.) **Lincoln:** Public Health Laboratory, St. Edmunds Chambers, Bank Street, Lincoln. (Telephone: Lincoln 8607.) **Liverpool:** Bact. Dept., City Labs., 126, Mount Pleasant, Liverpool. (Telephone: Royal 3636/7.) **London** (Colindale): Central Public Health Laboratory, Colindale Avenue, London, N.W.9. (Telephone: Colindale 6041 and 4031; Telegrams: Defender, Hyde, London.) **Maidstone:** County Laboratory, Maidstone. (Telephone: Maidstone 4121, Extn. 286.) **Manchester:** Public

Health Lab., York Place, Manchester, 13. (Telephone: Rusholme 1446.) **Newcastle:** Public Health Lab., Gen. Hosp., Westgate Street, Newcastle-upon-Tyne. (Telephone: Newcastle 34920.) **Northallerton:** Public Health Laboratory, County Hall, Northallerton, Yorks. (Telephone: Northallerton 88.) **Northampton:** Public Health Laboratory, General Hospital, Northampton. (Telephone: Northampton 347.) **Norwich:** Public Health Laboratory, Isolation Hospital, Bowthorpe Road, Norwich. (Telephone: Norwich 21095.) **Oxford:** Public Health Laboratory, Walton Street, Oxford. (Telephone: Oxford 47884/5.) **Sheffield:** Public Health Lab., City General Hospital, Sheffield, 5. (Telephone: Sheffield 36751.) **Stafford:** Public Health Lab., Martin Street, Stafford. (Telephone: Stafford 377.) **Wakefield:** Public Health Laboratory, County Medical Offices, Wood Street, Wakefield. (Telephone: Wakefield 3781.) **Winchester:** Public Health Laboratory, Royal Hampshire County Hospital, Winchester. (Telephone: Winchester 3807.)

Stocks of prophylactic for diphtheria immunization—A.P.T. and T.A.F.—will be held by medical officers of health for use as required. They will make their own arrangements about issuing it to general practitioners.

Correspondence

Supply of Doctors' Cars

Medical practitioners write to us from time to time about their difficulties in obtaining motor-cars, and one has stated recently, "In my particular locality not a single ex-Service doctor has been able to purchase a car, despite correspondence with the manufacturers, distributors, and agents." The following letter from the Society of Motor Manufacturers and Traders, Ltd., may therefore be of interest.

SIR,—From time to time there have been comments on the question of the supplies of new cars for doctors. The motor industry and trade have constantly had this question under review and we wish to place on record the following points.

At no time has the industry undertaken to give absolute priority to doctors. The term used is "preferential delivery," and that is only intended to apply in cases where a doctor has no serviceable car or no car at all.

As delivery dates for the ordinary public have been anything up to three or four years and now may be considerably more, a doctor is getting preferential delivery if he obtains a car in, say, one year less time than the ordinary public. That may still mean that he has to wait a very considerable time, and doctors are not expected to refrain from placing an order until their car is on its last legs.

The efforts of the trade to meet doctors' requirements have been frustrated to some extent by a minority of doctors who have abused the privilege. The trade holds a considerable body of evidence of this abuse.

The position is complicated by the fact that the orders by doctors are by make. All makers are exporting a very large percentage indeed of their output, and some, of recent months have been exporting practically the whole of their output. Orders placed for these latter makes, therefore, have been and will be even still further delayed.

It will be recalled that the export percentage for motor-car has been consistently increased over the last two years, and this has added to the difficulty of forward planning of deliveries. In fact, less than a quarter of the number of new cars that were available each year before the war are now allocated to the home market, despite the enormous pent-up demand.

A recent survey of the position has been made and it demonstrates that distributors and retailers have been giving preferential delivery of cars to doctors. No less than 47% of doctors' orders have been fulfilled in the last two years, whereas in the same period only 18% of orders placed by all other users have been fulfilled. Other users include Government departments, police, nationalized corporations, large industrial fleet owners as well as other essential users.—We are, etc.,

R. GRESHAM COOKE,

Director,

Society of Motor Manufacturers and Traders, Ltd.

A. W. GRAFTON,

Secretary, Motor Agents Association, Ltd.

Seating at Representative Meetings

SIR.—The position with regard to the seating of representatives at the Special Representative Meeting last month was chaotic. Dr. Stephenson had raised the question of some organized form of reservation, and the Council's reply was very feeble. The fact that there are not enough seats to go round was made an excuse for limiting reservation to individuals, so that Groups were scattered all over the hall, and the scramble for seats between 9 a.m. and 10 a.m. was unseemly and deplorable. The fact that there is a shortage calls for organization rather than *laissez-faire*.

I suggest that this organization might be on the following lines:

(1) Elimination of desks so as to provide sufficient rows of seats to accommodate the whole Representative Body on the floor of the hall.

(2) What desks can still remain should be at the back of the hall, so that crowding is near the speaker rather than at the far end, and the disappointment of having to be at the back may be balanced by having a desk on which to express one's feelings.

(3) Seats should be allotted before the meeting to Groups by ballot, and the Group secretaries should be responsible for sending in the number required beforehand.

It all means a little extra staff work, but it would be very greatly appreciated, and it would be well worth while. Other representatives may have better suggestions, and this letter is intended to bring the matter up and to keep it before the Agenda Committee until order is restored out of the present chaos.—I am, etc.,

Great Dunmow, Essex.

G O BARBER

Mortuary Accommodation

SIR.—The Annual Report of the Council of the B.M.A. (Supplement, April 10, p. 87, Section 118) states that in March, 1947, the Minister of Health was asked if he would exercise his powers under Section 198 of the Public Health Act, 1936, to require local authorities to provide mortuaries and, where necessary, suitable premises for post-mortem examinations. The Minister, quite rightly, did not feel justified, in view of the predominant claim of housing, in taking any action at the present time. Nevertheless, the B.M.A. Council now proposes (para. iv) that the Minister be asked to give the matter his urgent attention, recommending that mortuaries be established at central points in each coroner's jurisdiction with refrigeration, post-mortem rooms, and "with facilities for histological examinations"; and (para. v) "that in general local hospital mortuaries be not utilized for this purpose."

The extravagant expenditure in setting up such establishments, save perhaps in the largest cities, could never be justified in times of plenty; even to think of it in these days of economic distress is ludicrous. The correct place for the performance of coroners' necropsies is a properly equipped hospital post-mortem room. Why have two buildings, two lots of mortuary attendants, and two histological units when one will do? And why this unnecessary demand on the pathologist's time in travelling from one place to the other?

The present position does not call for so drastic a remedy as the B.M.A. Council imagine. Adequate mortuary accommodation is available in most local authority areas, and there are hospital post-mortem rooms within reach of practically all the coroners if they care to make use of them. Many of the coroners do in fact now cause the cadavers to be moved to the pathologist's post-mortem room, where usually there is also good mortuary accommodation. But there are some who are not clear as to the difference between a mortuary and a post-mortem room and who, rather than cause the body to be moved, are content for an examination to be performed under primitive and often well-nigh impossible conditions. This reluctance to help the pathologist is not, as we have heard it stated, out of respect for the dead or for the relatives, but to economize in transport, a pathologist (at 6d. or 1s. a mile as laid down by the local authority) costing less than an undertaker (perhaps 2s. 6d. a mile on the average).

For this reason, one can only deplore the B.M.A. Council's recommendation, "That as an interim measure urgent consideration should be given to practical steps for mobilizing pathologists and enabling them to travel to the various outlying mortuaries with fully equipped motorized laboratories." This grotesque suggestion is completely at variance with the known wishes of pathologists,

who are presumably the "competent practitioners" referred to earlier on in the report. Is it really seriously suggested that pathologists should travel round in fully equipped motorized post-mortem rooms with self-contained running water and drainage, or is the "fully equipped motorized laboratory" another name for the pathologist's car containing a bag of instruments?

It was anticipated that the appointed day would see the end of this archaic and literally parochial practice which pathologists have for so long condemned and which the B.M.A. Council is now recommending. It is to be hoped that the Minister will reject paras. 118 (iv, excluding the last sentence), (v) and (vi), and 119 of the Council's otherwise admirable report.—I am, etc.,

Worcester.

MEDICAL INSURANCE AGENCY

The annual meeting of the Medical Insurance Agency was held on June 3, when a quite exceptional expansion of all branches of the Agency's business in 1947 was revealed. Rebates of premium to members of the profession amounted to £11,060, and the allocations to medical charities will, largely by reason of the covenant system, benefit them by about £15,000: a sum of £1,000 was entrusted to the Royal Medical Benevolent Fund to be used entirely at discretion in connexion with either a second edition of Westmoreland Lodge, which was opened last February, or the provision of accommodation for sick or bedridden beneficiaries. A "sick-bay" hostel is a logical and necessary development of the Westmoreland Lodge venture. During the past two years the "Loans on Practises" scheme, approved by the B.M.A., has brought hundreds of new clients to the Agency, but this activity has, of course, now ceased. At the meeting on June 3 Dr. J. A. Brown, Sir Francis Fraser, Sir Robert Hutchison, Dr. Roche Lynch, Sir Ewen Maclean, and Mr. H. S. Souttar were reappointed members of the committee of management for the ensuing three years. Dr. James Fenton was reappointed chairman and Dr. Henry Robinson honorary secretary. A vote of thanks to the manager and staff was recorded with enthusiasm.

The Agency was started in 1907 on the joint initiative of the then Editor of the *Journal*, Dr. (later Sir) Dawson Williams, and the then Editor of the *Lancet*, Dr. (later Sir) Squire Sprigge. The increasing value of the Agency to the medical profession is clearly proved by this year's report. It has established its claim to provide the medical profession with skilled, honest, and unbiased advice in insurance matters.

Association Notices

N.H.S. SUPPLEMENTARY OPHTHALMIC SERVICE

Notice to Ophthalmologists in Scotland

A separate central list of medical practitioners having the prescribed qualifications for participation in the Supplementary Ophthalmic Service will be compiled for Scotland. Application forms received at B.M.A. House, London, from practitioners in Scotland will therefore be automatically forwarded to the Scottish Secretary, B.M.A. House, Drumsheugh Gardens, Edinburgh, for submission to the Scottish Qualifications Committee.

Meetings of Branches and Divisions

NORTH OF ENGLAND BRANCH

The first meeting of the Spring Course of Scientific Meetings was held in the Royal Victoria Infirmary on March 11. Prof. F. J. Nutter demonstrated cases of disseminated sclerosis and discussed the disease, paying particular attention to its many modes of onset and its prognosis. This was followed by a lecture by Prof. F. A. E. Crew on the biological and medical aspects of marriage. He commented on the increase in the divorce rate and pointed out that marriage is a social institution and that the family is a biological unit for the security of the species. He also discussed the

tendency of Governments to become more paternal and to take over a considerable number of the functions of the parent and suggested that we must decide on what functions in life we can allow the bureaucrats to take over. There were 150 members present.

The second meeting was held at the Royal Victoria Infirmary on March 25, when Mr. W. A. Hewitson demonstrated cases of carcinoma of the breast. This was followed by a lecture by Prof. G. Grey Turner on some considerations in the surgery of the mouth and jaws. He discussed epithelioma of the tongue, its lymphatic spread and operative treatment, and malignant neoplasms of the jaw, stressing the use of preliminary gastrotomy in treatment. His lecture was illustrated by an excellent series of lantern slides. It was attended by a large number of members.

The last meeting of the series was held on April 8 and took the form of a "brains trust." The members of the team were Mr. C. Gordon Irwin, Prof. A. Kennedy, Mr. F. McGuckin, Dr. Gavin Muir, Dr. J. B. Tilley, and Dr. H. F. Wattsford. The question master was Prof. E. Farquhar Murray.

There were 130 members present and it was a very enjoyable evening, being both entertaining and instructive. More questions had been submitted than time permitted discussion of, but the questions dealt with ranged from purely surgical—"What is the present position of the injection treatment of varicose veins?"—to the political—"Should the Minister of Health be a doctor?" The opinion of the brains trust when replying to the question "Do you believe that physicians live longer than surgeons?" was that surgeons lived longer than physicians, but physicians ckd out more years. All the members agreed that if they were to begin their career again they would take up medicine once more. In reply to the question "On what points should a selection committee for candidates for medicine concentrate?" the brains trust was no very helpful, and it was left to Prof. Kennedy to expound the view that the function of the committee was merely to exclude those (1) who will fail examinations, and (2) those who will go mad in training. A question on whether abortion should be legalized on sociological and economic grounds provoked a good discussion. Eventually it was agreed that abortion could be agreed to on these grounds only in very rare cases.

MONMOUTHSHIRE DIVISION

The strength of the Division has increased slightly during the year there being 198 members at March 31 as compared with 192 in 1947. The executive committee of the Division met on nine occasions during the year and their business was mainly concerned with instructions and guidance from Headquarters on the National Health Service.

Five general meetings of the medical profession, at which members and non-members of the B.M.A. were present, were held during the year, and there was an average attendance of 59 people at these meetings. The most successful was held in January and was addressed by Dr. D. P. Stevenson, Deputy Secretary of the B.M.A. on "The Terms of Service under the National Health Service Act." The meeting was attended by 136 medical men and women and a vote at the end of the meeting showed that only three of those present were willing to take service under the Act as it then stood. After the Minister had replied to the Negotiating Committee's further general meeting of the profession was held, at which 60 members were present; 42 voted that they were unwilling to enter the National Health Service, while 14 voted for acceptance.

Despite the preoccupation of the profession with medico-political time was found during the year to hold four meetings connected solely with professional matters. An informative address was given in October to 65 members by Dr. Clarke-Kennedy on "Psychosomatic Medicine." In September a successful clinical meeting was held at which 39 members were present, and interesting cases were demonstrated by members. Also during September the opportunity was taken to exhibit the topical film of "Anterior Poliomyelitis," with which were shown films on "Nitrous Oxide and Ether Anaesthesia" and the "Surgical Treatment of Pyloric Stenosis"—the latter by kind permission of Mr. Rice-Edwards. In November an interesting demonstration of cases treated by plastic surgery was given by Mr. Emlin Lewis.

CORRECTIONS TO PROGRAMME OF ANNUAL MEETING

The Section of Anatomy and Anthropology meets on Friday, July 2, not July 1 as stated in the *Supplement* of June 12 (p. 162).

The address of Dr. J. C. Belisario, who is speaking in the Section of Dermatology (June 12, p. 162), should have been Sydney, Australia not U.S.A.

In the Section of Child Health the following lecture-demonstration has been arranged for Thursday, July 1, at 2.30 p.m. (Meeting Place: Agriculture Department; entrance, Tennis Court Road): "The State of Nutrition of German Children." Selected subjects are being brought on a visit to this country by Prof. R. A. McCance (Cambridge) and Miss E. M. Widdowson (Cambridge).

In the combined meeting of the Sections of Medicine and Surgery on Thursday, July 1, Dr. Rae Gilchrist (Edinburgh) will speak, not Dr. A. R. Gilchrist (Aberdeen).

BRITISH MEDICAL JOURNAL

THE JOURNAL OF THE BRITISH MEDICAL ASSOCIATION

Edited by
HUGH CLEGG, M.A., M.B., F.R.C.P.

VOLUME I 1948
JANUARY TO JUNE

KEY TO DATES AND PAGES

The following table, giving a key to the dates of issue and the page numbers of the BRITISH MEDICAL JOURNAL and SUPPLEMENT in the first volume for 1948, may prove convenient to readers in search of a reference.

Serial No.	Date of Issue	Journal Pages	Supplement Pages
4539	Jan. 3	1- 34	1- 4
4540	" 10	35- 86	5- 8
4541	" 17	87- 134	9- 14
4542	" 24	135- 184	15- 16

INDEX TO VOLUME I FOR 1948

READERS in search of a particular subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate headings—for example, Brain and Cerebral; Heart and Cardiac; Liver and Hepatic; Renal and Kidney; Cancer and Carcinoma; Child and Infant; Goitre and Thyroid. Subjects dealt with under various main headings in the JOURNAL have been set out in alphabetical order under their respective headings—for example, "Annotations," "Correspondence," "Leading Articles," "Obituary," "Reviews," etc. Original Articles are indicated by the letter (O).

A

- ASBESTHALDEN, Rudolf: *Medizinische Terminologie*, 433
- Abdominal pain, 949
- Abortion, threatened, Guerman test in (S. Bender), 683 (O); annotation, 696
- Atresia, Brod's, of tuba treated by surgery, penicillin, and sulphadiazine (Stanley Scott and Frank S. Preston), 296 (O); correspondence, 472, 618
- ART, Isaac A. (ed.): *The 1946 Year Book of*, 200
- Academy, Royal (annotation), 855
- of Medicine in Ireland: Primary sterility, 23—Bone conduction in otosclerosis, 263, correspondence, 569
- Accidents, road, 78
- Acetylcholine, 867
- Acetylcholinesterase and menstruation, 350
- Acetylcholinesterase, 552
- Actin, roseola, and β -Dilbeosul fer, 1059
- Adipic acid, 1230
- Adultery, K. V.: Penicillin and blood coagulation, 709
- ADAMS, A. WILFRED: The family doctor, 314—Avoid confusion, 1106
- Philip Edward Homer, obituary notice of, 478
- Addison's anaemia, cancer of stomach in (W. A. Bourne), 92 (O)
- ADENY, G. G.: Zest in old age, 759
- J. F. (and others): Representation of ophthalmologists and specialists, 950
- Adiposity in childhood, 1270
- ADLEY, Frances H.: *Gifford's Textbook of Ophthalmology*, 4th ed., 103
- Adrenal carcinoma: Unusual case, with note on application of new colour test (L. R. Boster and Jocelyn Paterson), 781 (O)—Adrenal tumour due to carcinoma of adrenal cortex (C. N. Armstrong and John Simpson), 781 (O); annotation, 795
- Adrenaline: Endopropia caused by adrenaline infusion and by insulin hypoglycaemia (Z. Z. Godofskii), 45 (O)—Discoloration of scleroses, 855
- Adrenals in malignant hypertension, 1076
- AFRI, M. A.: *Biharal Cancer*, 1129
- Air, radiological evidence of, 25, 368
- Airway: Effects of sex and thyroid hormones on rates of change in female rats (V. Kozacheky), 728 (O); correspondence, 1001—Flea for the seed, 1111—Prevention of infirmity (leading article), 1142
- AGUS, Thomas J.: The moral issue, 362
- AGNEW, Alex. P.: G.M.C. to mediate, 564
- L.R.C.: Treatment of myasthenia gravis, 122
- Agranulocytosis: Fatal case associated with "iridogenic" therapy (R. F. Ershovskii), 14—Treated with folic acid, 823
- AIRNTHLEY, H. H.: The paternal State, 515
- Albume infection, 630
- Alchison, Charles Umpherson, death of, 1013
- ALIBULANDA, Swami: *Hindu Psychology*, 453
- ALLOUANTINE, Th. (and P. MOZZONACCI): *L'Alphale et la Désintégration Fonctionnelle du Larynx*, 915
- Alcohol: Ethyl alcohol levels, 237—Effect of, as co-mutagen in E.S.R. (W. O. Sykes), 393 (O)—Effect of, 817—Alkalosis and effects of, 861; correspondence, 1060
- Alcohols anonymous, 654
- ALDER, Noel: Exercise in middle age, 954
- Aldridge, Bernard Henry Mooring, estate of, 562
- ALLEGANT, C. D.: Malignant syphilis, 737
- ALEXANDER, G. L.: Colonial Medical Service, 907
- J. Finlay: Income in N.H.S., 1045
- Alimentation, intravenous (H. E. Marsh), 4 (O)—correspondence, 823
- "Alkalosis" and effects of alcohol, 861; correspondence, 1050
- ALLAN, C. A.: Relief of pain in midwifery, 175
- Herbert William, estate of, 131
- ALLAN, Clifford: Remuneration of consultants, and specialists, 470
- ALLERGY:
- Asthma, allergic bronchitis: Beneficial effect of insulin hypoglycaemia, 46
- Auto-sensitization in, 770
- Book on, 603
- β -Tubocurarine chloride, idiosyncrasy to (T. Cecil Gray and John Halton), 784 (O); correspondence, 906, 954

ALLISON (continued).

- Ecz., 34
 Eye. Allergy and the (annotation), 57—Allergic conditions of, 597
 Food, 34, 184
 Hæmover. To *Cerebra via benadryl*, 276, 286—
 blood-regulated, 98
 Penicillin. Severe reaction after (J. F. L. Waller),
 150—correspondence, 277, 417—Case history of
 (R. A. Shaver), 547—Penicillin, beeswax, and
 allergy (I. Watson), 201
 Sugar, burnt, and, 184
 Staphylococcus (annotation), 303
 Tuberculosis, allergy and immuno in, 232

 ALLISON, D. R. (and R. G. Gordon): *Psycho-
 therapy, Its Uses and Limitations*, 603
 ALLOT, E. N.: Rh factor and blood transfusion, 655
 Almoners, future of, 78
 Almonds, treatment of, 133
 ALSTON K. SEVENING: Effect of thiocyanate on basal
 blood pressure, 520 (O)
 AMPHIB, A. J.: Smallpox and chicken-pox, 418
 Amblyopia, art. 90
 "Amelin" for diabetes (H. Whitaker), 545 (O)
 Anesthetics, essential, and intravenous alimenta-
 tion, 5
 Anorexia traumatica (annotation), 106
 Anomalous membrane ("Amnioplasin") grafts for
 eye, 676—(annotation), 106
 Anomalous treatment of, 113

 ANASTHESIA
 Anesthesia, 775
 Anesthesia, cancer of stomach in (W. A. Bourne),
 92 (O)
 Associated with trauma and septal defects,
 154
 Asthma, treated with folic acid, 823
 ESR corrected, 1165
 Haem, 547, 35
 Hypochromic, 35
 Iron in, 625, 73, 739, 753, 901, 1207
 Iron-deficient, refractory, treated with intravenous
 saccharated oxide of iron (L. S. P. Davidson),
 823
 Iron, R. H. of iron, 832 (O); annotation,
 739—correspondence, 901, 1207
 Megaloblastic Anaemia, acid (John F. Wilkinson),
 771 (O), 822 (O); leading article, 840—Of
 pregnancy, unusual case (M. Gillespie and
 A. M. R. Reid), 828 (O); leading article, 840
 Megaloblastic, 35, 701
 Pernicious Anemia, acid in treatment of, 772—(O)
 Pernicious, and the puerperium (L. S. P. David-
 son and others), 819 (O); leading article, 840—
 Isolation of anti-pernicious-sarcoma factor
 (anovine), 859—Mortality rates (1925-45),
 1166

 ANAESTHESIA
 Administration of anaesthetics, device for (G. C.
 Scurr), 356
 Apparatus. New general anaesthesia (H. Rex
 Marrett), 403—Portable (G. E. Hale Enderby),
 1043—Extension for Gordh needle (C. F.
 Scurr), 1102
 Book on general anaesthesia, 299
 Boyle-Davis gas. Modification for oral intubation,
 115 (C. M. Mea or), 267—correspondence, 417, 523
 Cures
 Dibutylarsine chloride. "Unjustified" use of,
 126—Inhalation, to (T. Cecil Gray and John
 Haxton), 781 (O); correspondence, 906, 954
 General, 676
 In children, 781
 Muscular, 781
 "Myasmin," 520—As relevant in children (W. H.
 Armstrong Davidson), 544 (O); correspondence,
 781
 Pugh William Ross—a chlorine anaesthetic, 86
 Spinal, in treatment of congenital megaloblastic
 (E. D. Telford and H. A. Haxton), 827 (O);
 annotation, 842
 Thiopentone: Convulsive properties of (R. L.
 Wynne), 48 (O); correspondence, 223, 276—
 And larval spin, 916
 "The land," a transport (C. F. Scurr), 802
 Trichloroethylene ("C" trileve"), Role of (Gordon
 Olfert), 195 (O); correspondence, 316, 367, 473,
 523, 662, 757—By-pass train, 595

Analgesia, local, in dentistry, inserting needle for.

- 1109
— obstetric, 232—Provided by domiciliary
midwives, 30, 1215—Intravenous procedures in
obstetrics, 671

- Analysis, surface, a spray device for (A. Owen-Flood), 114
Anaphrodisiacs, 233
Anaphylaxis, 276
Anaphylaxis, system, 340
Anaphylaxis, H. Harns, 585
(O)—Lymphatic connections of the subarachnoid space (E. J. Field and J. B. Brierley), 1167 (O)—
Cervical sympathetic paralysis (J. Donaldson Craig and C. G. Galt), 1187 (O)
ANDERSON, A. (and M. A. KROHMER): Exposure to D.D.T., 1132 (O)
— H. S. Laprel berries, 426
— Joseph Barcroft, ethnical notes of, 231
— K. H. and Phil ELLMAN: Calciferol in tuberculous peritonitis with disseminated tuberculosis, 394

 Premature babies, rickets in, 106

PREPARATIONS AND APPLIANCES:

Anaesthesia: Modification of Boyle-Davis gag for oral intubation (J. S. C. Monro), 267—Device for administration (G. C. Peirer), 356—New general apparatus (H. Rex Marrett), 403—Transparent "third hand" (C. F. Scurr), 802— "Trilene" by-pass tap (A. H. Gallely), 996—Portable apparatus (G. E. Hale Enderby), 1043—Extension of Gordh needle (C. F. Scurr), 1102
 Analgesia, surface, spray device for (A. Owen-Flood), 114
 Calliper-boot, demonstration walking (Horace Davies), 556
 Collapse therapy, simplified apparatus for (Finn L. Corrigan), 165
 Splint for obstetric paralysis (J. D. Cronin), 1253
 Transfusion needle for intravenous cannulization (J. H. Waelisch), 897
 Urethral sling operations, fascial bodkin for (Walter Calvert), 308
 Varicose veins, roughened needle-head, for treatment of (R. Rowden Foote), 556

PRESS, P. (and M. BRUNNER): *Tuberkulose-Probleme im Kanton Zürich*, 52

Pressure, intra-abdominal and intrauterine, 856

PRESTON, F. S.: Penicillin and gonorrhoea, 1207— (And P. L. RUTHERFORD): An Arab custom, 572

— Frank S. (and Stanley Scott): Brodie's abscess of tibia treated by surgery, penicillin, and sulphadiazine, 296 (O); correspondence, 472, 618

PRICE, E. W.: Localization of deep pain, 366
 — John: Central placenta praevia, 708

— L. Woodhouse (and Richard SPITZER): Solitary myeloma of mandible, 1027 (O)

Prickly heat: Simple remedy, 76, 228, 317, 525, 573, 811, 859—Aetiology of, 228—And tropical ashyema, 317—Prevention of, 758

PRIMROSE, E. J. R.: Training in accountancy, 709

Prisoners of war in Far East, scrotal dermatitis in (A. W. Frankland), 1023 (O)

Prisons: health of prison population (annotation), 206

Procaine: In asthma, 483—Penicillin and, 582—Intravenous, in obstetrics, 671

Proctology: Radical excision in carcinoma of rectum, with conservation of the sphincters, 1100

Proctid displacement method, 1014

Progestrone and threatened abortion (annotation), 696

Prolapse, pessaries for, 425

Prophylaxis, measles, 174

Prostate: Castration or stilboestrol for prostatic cancer, 425—Recent trends in treatment of obstruction (Arthur Jacobs), 1231 (O)

Prostatectomy, pelvic osteitis after, 671
 — immediate, for retention of urine (G. A. Bagot Walters), 638 (O); correspondence, 756

Prostatectomy, retropubic, 964

Prostatitis, residual, 75

Protein: Role of, in intravenous alimentation, 4—Hydrolysis, 5—Hydrolysis of, in cartilage and bone (P. Pincus), 687 (O); annotation, 697 (O); correspondence, 857, 1000, 1109

— depletion and resistance to infection (annotation), 844

Prothrombin, estimation of, 320

Prowse, John Skardon, estate of, 328

Prurigo, p-aminobenzoic acid for, 859

Pruritus, treatment of, 904, 1001, 1210

— generalized, 718

— treated with antistin, 875

Psoriasis: Injection of vitamin D in, 483—Treated with antistin, 875—Pregnancy and, 1060

PSYCHIATRY:

After-care of mental patients, 653

Books on, 789, 836

Committee, Representative Psychiatric, 131

Electro-narcosis, 1044, 1056

Mental deficiency: Treatment of: young mental defectives, 283—Statistics, 1010

Schizophrenia, endocrinology of, 894

Therapeutic social clubs: adventure in social psychiatry, 211

Psycho-analysis: Books on, 51, 1187—Psycho-analytic concept of origin of depression (W. Clifford M. Scott), 538 (O); correspondence, 1051—In hospital, 558

Psychology: Books on, 15, 255, 789—Insomnia and loss of memory, 182—Juvenile delinquency (leading article), 203—Psycho-analytic concept of origin of depression (W. Clifford M. Scott), 538 (O); correspondence, 1051

— educational, 578

Psychotherapy: In prisons (book review), 602—Current, 983

Pteroylglutamic acid, 771, 825

Public health: Centenary of, review of brochure, 786—Leading article, 886—Rise of health legislation in England and in London (E. Ashworth Underwood), 890—Dinner at Guildhall, 945

— Laboratory Service (G. S. Wilson), 627 (O), 677 (O); leading article, 695

PUDDY, E.: Remember Willemsen, 166

Puerpium and pernicious anaemia of pregnancy (L. S. P. Davidson and others), 819 (O); leading article, 840

PUGMIRE, S.: Decentralize power, 617

Pulmonary heart disease, 21

— See Lungs

PURDON, W. Brooke: The Northern Ireland Act, 516

PUXON, Margaret: Pain in childbirth, 1255

PYBUS, S. T.: National Health Service, 71—The Act or liberty, 312—Practice under N.H.S., 409

Pyelonephritis and hypertension, 282

Pyloric stenosis, hypertrophic: In the adult (A. Hobson), 99 (O); Congenital, 4 cases in brothers (A. A. H. Gallely), 100 (O)

Pyopericardium: case tenor (A. L. Wingfield), 451; correspondence, 568

Pyribenzamine, 869

Pyridylethylamine, 867

Pyrogens, 377

Q

Quadruplegia, traumatic, treated with curare in oil, 289

Queensland fever ("Q" fever), spread of, 1145; correspondence, 1255

QUENU, J. (editor): *Nouvelle Pratique Chirurgicale Illustrée*, Part I, 736

Questions, Notes, and Comments:

Acetylalicyclic acid and menstruation, 330

Achondroplasia, 582

Acne rosacea, 1014—Stilboestrol for, 1059

— vulgaris, 1220

Actinomycosis, penicillin for, 866

Adrenaline: discoloration of solutions, 865

Alcohol: In life, 716—After death, 716

Allergy: Food, 34, 184—Burnt sugar and, 184—And immunity in tuberculosis, 282—Autosensitization, 770

Alopecia, treatment of, 133

Amenorrhoea in glass-cutters, 717

Amoebiasis, treatment of, 818

Anaemia: Iron in, 625—Corrected B.S.R. in, 1165

Anaesthesia, muscular relaxation during, 236

Anaphrodisiacs, 283

Angina pectoris, testosterone in, 484

— Vincent's, penicillin for, 1220

Angioneurotic oedema, 1120

Antibodies, passage of, from foetus to mother, 483

Antrochoanal polypi, 666, 1014

Apo'ogy, 818

Arthritis, rheumatoid: "Prost'gmin" in, 236—Vitamin D in, 717—Early signs of, 770

Ascariasis, treatment of, 85

Asthenia, neuro-circulatory, 964

Asthma procaine in, 483

Bile acids, estimation of, 626

Blood: Effect of heat on B.S.R., 484—From umbilical cord, 584

— donors, menopausal, 584

Questions, Notes, and Comments (continued):

Blood pressure: Normal readings, 865—High diastolic, in the elderly, 1269

Boils: Recurrent attacks of, 332—Multiple, 1220

Bone cavity, chronic suppurating, 531

Breast: Swelling in boy's, 532—Development, 583—Shrunk, 916

British diaries: Information wanted, 238

Bronchial spasm, relaxation of, 183, 332

Calcium: By mouth, 426—And vitamin D in fractures, 717

Callosities, treatment of, 1120

Cancer: Castration or stilboestrol in prostatic, 425—Immunity to, 769—Thorotrast and sarcoma formation, 866

Cataract, 531, 626

Catarh, nasal, sulphamamide powder in, 482

Cavernositis, fibrous, 332

Cellulitis of nose, 818

Cervix uteri and perineum, distance between, 1060

Chicken-pox and herpes zoster, 716

Chillblains: Vitamin D for, 182—Of nose, 184—Treatment of, 330, 378, 532, 626

Children: Archives of Disease in Childhood, 626—Care of teeth, 1165—Adiposity in, 1220

Cholera, introduction of, into Egypt, 866

Cleft lip, repair of, 237

Cod-liver oil, alternatives to, 85

Colitis, ulcerative, and iritis, 583

Constipation in an infant, 34, 184, 238, 378

Curare and smooth muscle, 672

Cystinuria: Control of, 376—Inheritance of, 671

Deaf-mutism, inheritance of, 33

Deafness, congenital, and German measles, 1014

Death: Cases for the coroner, 671—Comparison of mortality rates, 1166

Demodex infestation, 376, 584

Dextro-amphetamine sulphate, 532

Diabetes mellitus and heredity, 718

Diarrhoea due to *Salmonella typhi* murium, 1014

Diazepam in leprosy, 582

Dicoumarol and heparin in thrombosis, 425

Dienoestrol, 582

Diet: "Man value" in dietetics, 376—After total gastrectomy, 769

Dimethyl phthalate, diluent for, 964

Diphtheria: Mixed diphtheria toxoid and pertussis vaccine, 134, 738—Posture in, 236

Disinfection of ambulance after removal of infectious case, 283

Disk prolapsed cervical, 625

Döderlein's bacillus, 818

Dreams of persons born blind, 1270

Drug addiction, 133

Drugs: Prescribing dangerous, 182—Naming, 916

Dysmenorrhoea, 377

Ears: Piercing, 85, 626, 718—Wax in, 182

Egg, white of, 183

Eneuresis, 237—In young adults, 134, 184, 238, 426

Epilepsy: Pregnancy in an epileptic, 329—Fits a menstrual period, 484

Erysipelas, infective recurrent, 331

Ethyl alcohol levels, 237

Exercise in middle age, 816, 964

Faeces: estimation of faecal fats, 332

Fat atrophy due to insulin injections, 133

Fever, prolonged, of unknown origin, 331

Flatus in the elderly, 818

Formalin, toxic effects of, 183

Fractures: Closed-plaster treatment, 377—Vitamin D and calcium in, 717

Frequency, nocturnal, in elderly men, 532, 672

Glucose-saline, keeping qualities of, 1166

Glycosuria, renal, in a boy, 329

Great anticipations, 818

Gumma, orbital, treatment of, 1060

Haematemesis, repeated, in polycythaemia, 916

Haemoglobin estimation: Tallqvist method, 33, 332

Haemoptysis, causes of, 377

Hagner's operation, 484

Hair: Superfluous, 34—Thorium for baldness, 425, 584—Vitamin B and growth of, 484, 626

718—Curly hair and pregnancy, 770

Hand injury: assessment of disability, 583

Hanging, judicial, 184

Hay-fever, due to ragweed pollen, 964

Heart attack after alcoholic excess, 817

Heart-block, recovery following, 283

Heparin and dicoumarol in thrombosis, 425

Herpes zoster: Post-herpetic muscular palsy, 331

— Chicken-pox and, 716

Hiccup, persistent, 237, 378, 532

Hirschsprung's disease, treatment of, 964

Honey, food value of, 816

Hospital: Polish children's, 672

Hypertension: Pyelonephritis and, 282—Pitressin in, 1120

Income tax, 818, 1270

Incontinence of urine in elderly, 817

Industry: Fitness for work in compressed air, 85

238—Harvard of sodium chromate, 182

Infants: Constipation in, 34, 184, 238, 378—Tetany, 283—Oral administration of penicillin to, 332—In tuberculous families, 376

Infertility, male, 1166

Inoculation: aseptic technique, 425, 672

Insomnia and loss of memory, 182

Iodine: And hydrogen peroxide, 378—In whale meat, 378

Iritis and ulcerative colitis, 583

Labia minora, enlarged, 85

Lacrimal hypersecretion, 672

Relapsing fever. See Fevers
